SOPHOCLES, a celebrated tragic poet, was born at Athens, 497 B. C. In his twenty-eighth year he entered the lists with Æschylus and gained the theatrical prize, and in the opinion of the best critics both of Greece and Rome, he has been placed above all the ancient writers of tragedy. Sophocles was distinguished also as a general. He commanded the Athenian armies, and in several battles he held the supreme command along with Pericles. He exercised also the office of Archon. He is said to have died of joy at the advanced age of ninety, in consequence of having obtained a poetical prize at the Olympic games. Of the one hundred and twenty tragedies which he composed only *seven* are extant, viz. *Ajax, Electra, Oedipus, Tyrannus, Antigone, the Trachiniæ, Philoctetes*, and *Oedipus at Colonos.* The best editions of this author are those of Capperonier, 2 vols. 4to. Paris, 1720; Johnson's, in 3 vols. 8vo. Oxon. and Lond.; Bruncks, 4vols. 8vo. and Musgrave's, Oxon. 2 vols. 8vo.

SOREL, river of Lower Canada. This stream, the outlet of Lake Champlain, is known by several local names; towards Lake Champlain it is called Richelieu river, near Lake St. Joseph the Chambly, and near its entrance into St. Lawrence the Sorel. From Windmill Point in Vermont, where the current from Lake Champlain begins, to the mouth at the town of William Henry in Lower Canada, the course of the Sorel river is a little east of North, 72 miles, and with but few partial inflections. The valley of the Sorel is indeed only a part of that very remarkable glen or chasm in the earth's surface, occupied by the Hudson river, Lake Champlain and Sorel. The stream is ample and rendered less subject to fluctuation from the seasons than rivers which are formed without lakes, but is much impeded from shoals and rapids. It serves, however, as a channel for a very considerable down stream navigation.

DARBY.

SORRENTO, a town of Naples, delightfully situated in the middle of gardens, on the south side of the Gulf of Naples, between the mountains of Massa and Vico. It was the birth place of Tasso. The number of ancient marbles, and the ruins of temples attest its former reputation and importance. Population, 4200.

SOUTHAMPTON, an ancient town and burgh of England, and capital of the county of Hampshire, is pleasantly situated on a tongue of land bounded on the south and west by the large estuary called Southampton water, and on the east by the river Itchin. The town contains many handsome streets, which are built of bricks, instead of timber, which was formerly the custom. The High Street, which runs northward from the quay, is upwards of half a mile in length, and is no less remarkable for its elegance and spaciousness, than for the resemblance it bears to the High Street of Oxford. Owing to the circumstance of the town being built upon a slightly elevated ridge, and the soil being of a gravelly nature, the streets are kept remarkably clean and dry. They have also the advantages of being well paved, and regularly lighted and watched. The public buildings are five parish churches, St. Michael's All-Saints', Holyrood, St. Lawrence, and St. Mary. There were formerly six churches; but the parishes of St. John and St. Lawrence being united in the reign of Charles II. it was deemed expedient to pull down the church of the former at the same time. St. Michael's is the oldest of the five, and is ornamented by a lofty octagonal spire, which was erected about sixty years ago for the purpose of guiding ships entering the harbour. On the north aisle of the chancel, a handsome monument has been raised to the memory of the Lord Chancellor Wriothesley; and in the opposite aisle on the south, there is a very curious antique font. It is in this church that the ceremony of the mayor being sworn into office takes place. All-Saints' church is a handsome modern building in the Grecian style. The remains of Captain Carteret, the well known circumnavigator, and of Bryan Edwards, the celebrated historian of the West Indies, are interred here. Holyrood church is a spacious edifice, with a tower at the south-west angle, and a colonnade in front, generally called the Proclamation, where the hustings is erected, and the poll taken at elections. In the interior of the church, there are several monuments, and a fine organ. The churches of St. Mary and St. Lawrence are no way remarkable. There was formerly a house of Grey Friars, instituted in 1240, of which hardly a trace now remains. At the north end of the High Street, there is a curious old gatehouse called the Bar gate. On its north front are delineated two gigantic figures, one on each side of the gateway, which, according to tradition, were intended for the giant Ascupart, and Sir Bevois of Southampton, who slew him in combat. Southampton being much frequented during the summer months by visiters, for the purpose of enjoying the sea-bathing, and drinking the chalybeate water, a spring of which, highly esteemed for its medicinal qualities, rises about a hundred yards to the west of Bar gate, is enabled to support a theatre, and assembly and ball rooms, which are beautifully situated, and elegantly fitted up. The Audit house is a handsome edifice, in which the sessions are held; it is also the repository of the records and regalia of the corporation. There is a free grammar school, which was instituted so long ago as the reign of Edward the Sixth. There is likewise a charity school for ten boys, founded by Alderman Taunton of this town; and Sunday schools, and a school of industry, were established in 1786, and are still continued. Near the entrance of the town on the right, is a neat range of alms-houses, built about fifteen years ago, to accommodate eighteen poor widows, who each receive two shillings per week from a legacy left by Robert Thorner, Esq. of Baddesley, who died in July 1690. There is an hospital, called Domus Dei, or God's house, founded in the reign of Henry the Third, for four old men and as many women. The poor house is an extensive, modern, and convenient structure. Near the town, on the north, barracks have been lately built by government, for the reception of cavalry, which occupy nearly two acres of ground. The principal trade of this port is with Portugal, the Baltic, and the Islands of Jersey and Guernsey. Wine and fruit are imported from Portugal. Tar and pitch from Sweden; hemp, iron, and tallow from Russia. English iron is brought by the coast from Wales; and coals, lead, and glass, from Newcastle. Southampton is allowed to export 6000 tons of unwrought wool yearly to Jersey and Guernsey; the most part of which is returned, converted into coarse knit hose. The manufactures are inconsiderable, being chiefly silk and carpets. Frigates and sloops of war were formerly built here, but ships of smaller burden only are now constructed. Southampton is governed by a mayor, recorder, sheriff, two bailiffs, and a common council, (formed of all those who have filled the foregoing offices,) a town clerk, two coroners, and other inferior officers, and is a county of itself, being styled the town and county of the town of Southampton, a privilege bestowed on it by King John, and, as such, is independent of the lord lieutenant and sheriff of Hampshire, having its own clerk of the peace, which office was added by charter to that of the town clerk. It returns two members to parliament, who are elected by about 700 voters, consisting of the burgesses, and those inhabitants who pay scot and lot. The mayor is admiral of the liberties from Southsea Castle to Hurst Castle, and half sea over from Calshot to the Isle of Wight. It was in this town that the Earl of Cambridge, Lord Scrope of Masham, and Sir Thomas Grey, were executed, for conspiring against the life of King Henry the Fifth. The number of eminent men born at Southampton is not very great; the most remarkable are Nicholas Fuller, an eminent divine, born in 1557, who died in 1622-3; Dr. Isaac Watts, born in 1674, who died in 1748, and Richard Pococke, a celebrated traveller, and a bishop of Meath, born in 1704, who died in 1765. In Southampton four fairs are held annually, the principal of which is opened by the mayor and bailiffs with much ceremony; there is a market every Tuesday, Thursday, and Saturday, which is held in an area behind the Audit House, and is plentifully supplied with fish and provisions of every kind, and of the best description.

The population in 1821 was as follows:—

Houses	2,161
Families	2,960
Do. in trade	2,331
Males	5,931
Females	7,422
Total population	13,353

See the *Beauties of England and Wales*, vol. vi. p. 125.

SOUTHAMPTON, county of Virginia, bounded south by Northampton and Hertford counties of North Carolina, south-west by the Meherin river, or Greenville county of Virginia, on the north-west by Greenville, Sussex, and Surry counties, and on the east by Blackwater river, or Isle of Wight and Nansemond counties. Greatest length from south-west to north-east 40 miles, and the area being within a trifling fraction of 600 square miles, the mean width about 15 miles. The outlines are nearly triangular, with the base to the north-west, and opposite angle on North Carolina, near the junction of Nottoway and Blackwater rivers. Bounded north-east and east by Blackwater, south-west by Meherin, and traversed nearly centrally by Nottoway river, the navigable facilities of this county are remarkably abundant. The whole of the preceding rivers unite and form the Chowan 9 or 10 miles by water within North Carolina, and continuing their original course south-east, open into Albemarle Sound. Extending from N. lat. 36° 30′ to 36° 54′, Southampton comes into the region where cotton can be successfully cultivated, and lying below the falls of the river, the surface is but moderately elevated above tide water. The seat of justice and principal post-office is at Jerusalem, on the Nottoway, near the centre of the county, N. lat. 36° 39′, and only 6 minutes of longitude west of the meridian of Washington City. Population of the county in 1810 was: Whites, 3216; coloured persons, 908, and slaves, 3350; total 7474:—in 1820, whites 3369; free coloured persons 1013, and slaves 3323; total 7705.

SOUTH AMERICA.

South America, one of the great continental extensions of the earth, and to which has been given a very improper relative name, since though confounded under one general term, the two sections of the newly discovered continent stand much more detached from each other than do Asia and Africa, and beyond comparison more than Europe and Asia. In general features, and in vegetable and animal productions also, the two Americas stand very strongly contrasted.

South America reaches in a very nearly north and south direction from Cape Vela, N. lat. 12° 15′, to Cape Horn, S. lat. 56°, or through above 68 degrees of latitude, 4743 miles. The greatest breadth is almost exactly at right angles to the greatest length. From Cape San Roque to Cape Blanco on the Pacific is very near 44 degrees of longitude, on from 4° to 5° S. lat. giving to the continent a width of upwards of three thousand miles.

On even a cursory glance on its map, coloured to represent, not the political, but natural subdivisions, the mountains and rivers of South America present themselves as the most distinguishing features. We find the continent united to North America by a mere strip of land, and expanding rapidly to the south-east. The connecting isthmus is really or apparently continued southward in an immense system of mountains, to which the original Spanish discoverers bestowed in their just admiration the title of Cordilleras. In the first ages of Spanish discovery, the Andes, as they are now universally called, were considered as continuous from one continent to the other, but more recent and accurate observation has rendered the connexion doubtful between the mountains of North and South America. Without attempting to decide the problem, we may proceed to regard the Andes of South America as an immense system of mountains stretching along the western side of that continent in all its length, and dividing it into two very unequal inclined planes. Between the Andes and the Pacific Ocean, the slope of land does not average one hundred miles in width, though extending along an inflected line of upwards of sixty degrees of latitude.

Rising from this confined border, the system of the Andes extends in lateral ridges, with unequal intervening vallies; the system extending in width from 100 to 200 miles. Here occur many of those elevated, and, from their approach to the equator, habitable vallies, or rather plateaus, which vary the features of every continent, but which in South America deserve particular notice. This will appear from a comparative view. In Europe, the table land of Spain is about 1900 feet above the level of the ocean. The table land of the Alps rises to about from 1300 to 1900 feet, and that of Bohemia and Silesia perhaps at a mean of 1400 feet. The highest level in France* is Auvergne, which rises to 2360 feet above the ocean level. The central plateaus of Asia and Africa are not very accurately determined, but must be far more elevated than the high plains of Europe.

In South America,† the Cordilleras of the Andes exhibit at immense heights plains comparatively level. Such is the plain between the sources of the Meta and Magdalena, N. lat. 3° 5′, elevated 8413 feet, where on its surface stands the city Santa Fè de Bogotà. Some of the vallies and plateaus of Peru are equally, if not still more elevated. But the volcanic region of Pichincha, only 13 minutes south of the equator, sustains the city of Quito at the height of 9500 feet above the Pacific.

The enormous summits or peaks of this vast system may be said literally to pierce the heavens, and not only reach, but pass the region of perpetual snow. Though it is probable that the Andes of Chili are as high as those of Colombia, the latter part of the system has been scientifically measured, whilst the more southern chains have not been visited by travellers of adequate activity and science. The following tabular view contains the height of the most remarkable peaks of the Colombian Andes:—

Chimborazo	21,440 feet. ‡
Disca Casada	19,570
Cayamba Urcu	19,392
Antesana	19,152
Cotopaxi	18,864
Altair	17,472
Sangal	17,152
Tunguragua	16,579

From this congeries of chains, peaks, and ridges, are precipitated westward into the Pacific, innumerable small, but locally interesting rivers. Of the Pacific river system of South America, the Guayaquil & Patia, neither having a comparative course of 200 miles, are nevertheless the most considerable streams, but on the eastern slope, the lengthened volumes of the Magdalena, Orinoco, Amazon, Plate, St. Francis, Colorado, and Cusu Leuvu, compensate for the brevity of those westward from the Andes.

Without noticing the minor branches, which would swell this article to an inconvenient length, it will be sufficient to review the great basins, not in their order of extent, but in respect to their position, relatively advancing from north to south.

The basin of Magdalena is long and narrow, and extending from south to north, nearly along the 2d and 3d meridian E. of Washington City, is in effect only an extension of the great vallies of the Andes. From Popayan, near the head of the basin, at an elevation of 5900 feet, the valley sinks gradually, but renders the rivers very unnavigable, from the great general descent. The entire basin stretches from N. lat. 2° to 11°, length 700; mean breadth about 120, area 84,000 square miles. Down this basin flow the various confluents of the two great constituent branches of the Magdalena, the Cauca and Magdalena proper. These streams unite at N. lat. 9°, and flowing thence one degree of latitude more northward, separate into two branches, which encircle the city of Carthagena, and enter the Caribbean sea 70 miles asunder.

The two minor basins of Atrato to the west, and Maracaibo to the east of that of Magdalena, belong to the Caribbean slope of South America, which is continued eastward to the gulf of Paria or Trinidad by a narrow strip.

From the sources of the Magdalena, a vast arm of the Andes extends north-eastward upwards of eight hundred miles, until imperceptibly merged in the plains of Coro. From this chain flow westward the confluents of the Magdalena, and to the eastward those of the Orinoco.

Entering the basin of Orinoco, introduces us to the most interesting river system of the earth. In this system, though only the third in extent, the basin of the Orinoco embraces an area of nearly four hundred thousand square miles, between N. lat. 2° and 10°, and from 2° to 17° long. E. from Washington City.

The particular confluents of this great river are too numerous to admit individual notice: it may suffice to observe, that the north-western branch, the Apure, draws its sources from the mountains of Merida and Paramo de la Rosa, and from the chain of Venezuela; some of its northern fountains rise within 40 miles of the Caribbean sea in the provinces of Maracaibo and Caracas.

The Meta, a longer, though perhaps in volume not so great a body of water, follows the Apure, and is again succeeded by the Guaviare. The latter rises in the main Cordilleras of the Andes, interlocking sources with the Rio Negro and the Magdalena.

The Orinoco properly so called, rises in the mountains of Guyana, N. lat. 5°, and long. 11° E. from Washington; flowing thence eastward, bends gradually to the south,

* Humboldt's New Spain, Black's translation, New-York, vol. i. page 37.

† Humboldt's New Spain, Black's translation, New-York, vol. i. page 41.

‡ Until recently, it was, as stated in the text, supposed that the first rank in height amongst American mountains was due to the Chimborazo, but it is now ascertained that it is more than rivalled by the peaks of Upper Peru. "In the eastern chain separating the valley of Desaguadero from the immense plains of Chiquitos and Moxos, are found the Nevado de Sorata, elevated 25,250 English feet above the ocean, and the Nevado de Illimani, of 23,000 English feet of similar relative elevation." The Sorata and Illimani were measured by Mr. Pentland. Vide Revue Encyclopédique, vol. 49, page 145—January, 1830. Paris.

south-west, and west, to where a stream flows from it into the Rio Negro. At the efflux of the Cassiquiari, the Orinoco has already flowed by comparative courses upwards of four hundred miles. The junction of the Amazon and Orinoco by the Cassiquiari and Rio Negro on an elevated plateau, is certainly the most singular and important fact in the natural history of rivers. This connexion, long denied after discovery, has been added to ascertained fact and science by Humboldt and Bompland, who actually passed from the Rio Negro by the Cassiquiari into the Orinoco.

With its great extent, variety of feature, and peculiar structure, the Orinoco is still an humble stream if compared to the Amazon. The latter basin sweeping from the Atlantic to the verge of the Pacific Ocean, embraces the central and southern equatorial regions of South America, and comprises the great superficies of two millions eight hundred thousand square miles. Similar to all very large rivers, there is an idle dispute respecting the source particularly deserving of the title given to the basin. Measured from the mouth, by the valley of the Negro, the length is about 1800 miles; by the Madeira, 2300 miles; but following the main volume and the Ucayale, it is 2900 miles. In a nearly western and eastern direction from the sources of the Tunguragua, the chord of the basin is about 2600 miles. If, therefore, we regard length of course as decisive of the question, the Ucayale is the main stream of the Amazon basin. The Ucayale and Madeira rise together from the Andes in the province of Cochabamba; but pursuing different directions, the former flows 2100 miles, and the latter 1800 miles before their union.

From the sources of the Ucayale, 17° S. lat., to the most northern branch of the Lauricocha, S. lat. 1°, the strip of land between the sources of the Amazon and the shore of the Pacific Ocean does not amount to an average of one hundred miles, and in many places is less than seventy miles wide.

To give a minute description of this wide spread and important basin would demand an extensive treatise; we must therefore be limited by a general view. If the windings are followed, by the most lengthened constituent branches, the Amazon flows from 3000 to 5000 miles. If we assume the Amazon proper, and Tunguragua, as the main stream, it receives from the north, beside innumerable branches of lesser note, the Pastaca, Piguena, Napo, Jupura, and Negro, advancing from head to mouth; on the contrary side, and proceeding in a similar direction, we find the Ucayale, Javari, Jutay, Jurua, Purus; the very lengthened Madeira, Tapajos, Xingua, and we may add the Tocantinas.

If the Amazon basin is compared with that of the Mississippi, the great extent of the former becomes more striking. The basin of the Mississippi is a trapezium of 1700 miles diagonal, with a mean breadth of 800 miles, area one million three hundred thousand square miles. The basin of the Amazon approaches a parallelogram of 2100 miles by 1400 miles, with an area of 2,940,000 square miles, forming by at least one half, the most extended basin on earth, having but one point of discharge, and affording much the most expansive navigable system of rivers, flowing towards a single recipient.

The great central valley of South America is continued southward from the basin of the Amazon, and between 13° and 36° S. lat. presents another very extended river basin, that of the Plate. The range of the Orinoco and Amazon basins are nearly at right angles to the chains of mountains, whilst on the contrary, the Plate basin ranges nearly parallel to the Andes and Brazilian systems of mountains.

The principal river of the Plate basin, the Paraguay, or as it is called in the latter part of its course, Parana, rises about S. lat. 13°, between the sources of the Madeira and Tocantinas, and flowing in an opposite direction from those of the Tapajos. Continuing a southern course through twenty degrees of latitude to its junction with the Uraguay, receiving in the intermediate distance, from the west, the Pilcomayo, Rio Grande, and Salado, and from the east, the great tributary branch the Parana, which latter name the united streams assume below their junction.

The whole of these vast arms with their minor branches, drain a navigable basin approaching the form of a square, with a mean of 1140 miles each side, area nearly one million three hundred thousand square miles. There is a remarkable equality of extent between the basins of the Mississippi and Plate, but what is more remarkable, they do not, when taken together, equal that of the Amazon. Again, if we add together the three great central basins of South America, we have a continuous valley sweeping over four million five hundred thousand square miles, and comprising within and contiguous to the torrid zone, more than the one ninth part of the land area of the earth.

The basin of the Plate, between S. lat. 20° and 24°, approaches to within fifty miles from the Pacific coast of Upper Peru; and on the opposing side of the continent, in the Brazilian province of St. Paul, the remote sources of the Parana rise but little more than thirty miles from the Atlantic Ocean. On S. lat. 24°, the continent of South America is 25 degrees of longitude, or 1575 statute miles wide, but the Plate basin has its greatest eastern and western extension on S. lat. 21°. Along the latter curve the basin itself is 25 degrees of long. wide, where the degree is 64.42 miles each, consequently it is upwards of sixteen hundred miles from the fountains of the Pilcomayo, in the Andes, to those of the Rio Grande branch of the Parana.

The breadth of the Plate basin varies less perhaps than does in that respect any other of the great river basins of the earth. From cape St. Antonio, the southern point of the bay of Rio de la Plate, to the sources of the Pilcomayo, in the vicinity of Potosi, is 1400 miles. A line drawn between these points is nearly the base of the basin, since it leaves the far greater part of the surface to the north-east. The breadth from the base contracts in advancing towards the Brazilian provinces, but will average at least 950 miles.

From so great a surface in temperate latitudes issue the various constituent streams which ultimately unite and form the wide estuary known as the bay of Rio de la Plata. This inlet opens to the Atlantic Ocean between S. lat. 35° and 36°, and long. 21° E. from Washington City, and is from the confluence of the Paraguay and Uraguay to the Atlantic 200, with a width varying from 30 to 150 miles wide.

In their general characters, the eastern and western confluents of the Plate vary essentially; the Parana and its branches are rather rapid currents, but the flow is gentle, or indeed sluggish, of the Paraguay and all its western tributaries. Such distinction of feature arises from the general structure of the continent of South

America. Rising as has been observed, by a rapid acclivity from the Pacific Ocean to the table land of the Andes, the short rivers flowing from so great an elevation westward, are brief in their courses, but rapid torrents until near their recipient. The streams again, which are discharged eastward, also are poured down the steeps with great velocity and frequent cataracts, until reaching the eastern verge of the Andes they enter on a plain, over which their channels are excessively winding and deeply cut, but currents necessarily sluggish.

The central plain of South America stretches with variant breadth, from the north-western sources of the Orinoco, to Patagonia, some places wooded, but in others presenting on the basin of Orinoco, the grassy tracts of Casanare, and Llanos of Cundinamarca and Pilcomayo; and again the wide spread Pampas of Buenos Ayres.

Crossing the central plain, the continent eastward from the basins of the Amazon and Plate, rises into a table land less elevated and less extensive than the Andes, but distinct, and from which the river currents fall with considerable force. The Amazon, flowing from the Andes, may be said to pierce the eastern plateau, and enter the Atlantic by a wide ravine between the Brazilian system of mountains and that of Guyana; but the tributary waters of the Plate issuing from the eastern and western plateaus, flow towards each other, unite in the heart of the continent, and continue over the central plain to the Atlantic.

Considering the Parana as the principal stream, a Spanish author observes, that " one of the peculiarities which most interests the curiosity of the observer, is the nature of its periodical inundations, very much resembling those of the Nile. In fact, we believe that there is not on the globe two other rivers, the qualities of which are more analogous to each other. Both have their sources in the torrid zone; and nearly equidistant from the equator, although in different hemispheres. Both disembogue themselves almost on the same latitude, directing their course towards their respective poles. Both are navigable for many leagues, and possess each their cataracts. Each of them has its periods of increase in the respective seasons, which cause it to rise in its channel, and inundate an immense tract of country."

With the preceding points of resemblance, it may be observed that the contrasts between the Nile and Rio de la Plata are equally striking. The Nile enters the final recipient by an extensive Delta, the Plate by a wide bay, and whilst the African river is environed in all the lower part of its basin by arid sandy plains, the Plate and Parana, with their confluents, drain an almost invariable fertile tract.

As a basin of navigation, that of the Plate possesses advantages fully commensurate, in a comparative view, with its relative extent. At the lowest depth, there is 15 or 16 English feet of water in the mouth of the Parana, and a much greater depth below in the bay, or above in the river. Vessels of 300 tons burthen are built above the junction of the Paraguay and Pilcomayo, and navigated to Europe and elsewhere. The Parana proper, the Salado, Rio Grande, Uraguay, Paraguay, and many others, present navigable channels from 200, to near 2000 miles, following the sinuosities of the rivers.

Beyond the basin of the Plate spreads a triangular slope from S. lat. 36° to 52°, being a continuation southward of the great plain of the Andes. The latter section is least known, and in the existing state of settlement and civilization in South America, the least important of the Atlantic portion of that continent. The Saladillo, Colorado, Cusu Leuvu, Camarones, and some other rivers, traverse the slope south from Buenos Ayres, but are mostly yet inhabited by savages, and as far as known not generally well calculated for civilized settlement. This tract is succeeded to the southward by another equally savage, and much more naturally rugged and inclement, and Patagonia, with the adjacent island of Tierra del Fuego, closes South America, by the most Austral continental protrusion of the earth.

Returning to more genial climes, and passing the ample estuary of the Rio de la Plata, we discover, skirting the Atlantic Ocean, a narrow extended but very interesting slope. The Brazilian table land, inclining a very little from the meridian towards N. E. and S. W. extends in broken fragments from the outlet of the Plate basin to that of the Amazon, giving existence and course to numerous rivers. If not on the same continent, and contrasted with the Orinoco, Amazon, and Plate, a respectable rank would be due to such rivers as Rio Grande, St. Francis, and Parnaiba.

Much confusion has arisen in Spanish American geography, by a multiplication of the same names. Several rivers are known by the title of Rio Grande, one of which, a very remarkable stream, is disembogued into the Atlantic Ocean, almost on S. lat. 32°. What is called here Rio Grande, is however only the mere discharge of a basin of about 500 miles from S. W. to N. E. and with a mean width of 140, area 70,000 square miles.

Two large lakes, the Laguna Patos, 150 by 50 miles, and the Laguna Merin, something less in length and breadth, lie parallel to the opposing coast, the latter discharging its water into the former, and both fed by numerous rivers flowing from the interior table land.

Between S. lat. 20° and 28°, and north-eastward from the basin of Rio Grande, extends a narrow zone, varying from about 150, to less than 50 miles wide, and 900 in length; having the Atlantic Ocean S. E. and the sources of the Parana N. W. Besides many smaller streams traversing this well watered tract, are the Ribeira and St. James, of considerable length of course. With S. lat. 20°, the Brazil slope of South America widens rapidly, the table land inclining west of north, and stretching towards the mouth of the Tocantinas. The rivers entering the Atlantic between S. lat. 11 and 20°, are excessively numerous, though of abridged course. The limited length of those rivers, as produced by one of those singular phenomena, which render the geography of South America peculiar. The St. Francis derives its highest sources interlocking with those of the Parana, within 200 miles from the Atlantic coast, and as far south as lat. 21°. Pursuing a northern course of 400 miles, the St. Francis inflects gradually to the north-east, east, and south-east, enters the Atlantic Ocean at S. lat. 11°, after an entire comparative course of upwards of 1100 miles, and in this long course overheading the intermediate Atlantic rivers.

On the same slope, and nearly due west from the mouth of the St. Francis, and interlocking sources with that river, and with the Tocantinas, rises the Parnaiba. The latter inclining to N. N. E. and after a comparative course of six hundred miles is lost in the Atlantic Ocean, at S. lat. 2° 40′.

Sweeping round the extreme eastern protrusion of South America, forming politically the Brazilian provinces of Pernambuco and Ceara, in a distance of 900 miles from the mouth of St. Francis to that of Parnaiba, the rivers are found still more confined in their courses than on any other part of the oceanic margin of South America; but from the estuary of the Parnaiba to that of the Amazon, or rather to that of the Tocantinas, the Pinare, Gurupy, Capim, and some others, flow from two to three hundred miles, before their exit into the Atlantic.

Passing the estuary of the Amazon, we discover between that outlet and the Delta of the Orinoco, another detached slope extending from south-east to north-west about one thousand miles, with a mean width of 150 miles; superficies 150,000 square miles. This region, to which, by a rare felicity, a general and elegant name has been given, Guyana, is nearly commensurate with the natural section we are describing, and from extended European colonization is a very interesting portion of maritime South America. Similar to the other parts of the oceanic border of that continent, the sea coast of Guyana is much indented by rivers, though only three, the Essequibo, Surinam, and Marowine, are of magnitude worthy notice.

The most considerable of these rivers, the Essequibo, is formed by two branches, the Cuyuni from the north-west, of 300 miles comparative course, and the Essequibo proper from the south, of 400 miles comparative course. Uniting at the town of Essequibo, the confluent waters open in a wide bay, which terminate in the Atlantic Ocean at N. lat. 7°.

The Surinam or Surimaca, rises in the same mountainous ridge as the Essequibo, but the former flowing eastward about 100 miles on N. lat. 4°, turns abruptly to the north, and continuing that direction, is finally lost in the Atlantic Ocean at N. lat. 6°.

The Marowine rises at N. lat. 1° 30′, and flowing thence northward, has a course of about 4 degrees of latitude, and is merged in the Atlantic Ocean one hundred miles east of the mouth of the Surinam.

The rocky, bold, but narrow slope skirting the Caribbean Sea from the Delta of Orinoco, to the Gulf and Bay of Maracaibo, completes our general survey of South America. From the Gulf of Paria, westward to the strait between the Gulf and Lake of Maracaibo, is 600 miles, but the mean width is probably less than 50 miles. The northern abutment of Colombia is continued westward of the Gulf of Maracaibo, by the provinces of Rio de la Hacha and Santa Marta. The extreme northern extension of South America is found in that peninsula jutting to the N. E. from the Delta of the Magdalena; Cape Falso, N. lat. 12° 12′, long. 5° 08′ E. from Washington, is, by Tanner's map of Colombia, the utmost northern cape of that continent, and forms part of a detached slope of about two hundred miles by one hundred. This peninsular declivity takes its name from a small river which falls into the Caribbean Sea at a city of the same name. The mountain torrent Rio de la Hacha, after a comparative course of little more than one hundred miles, forms the harbour of the city of Rio de la Hacha, N. lat. 11° 32′, long. 3° 48′ E. from Washington City.

We have completed a cursory survey of the natural features of South America, and proceed to a delineation of the political subdivisions of that continent.

Viewed as a whole, South America presents on its northern extremity the great Republic of Colombia. Excluding the savage regions towards the straits of Magellan, the southern part is occupied by the Argentine Republic, or as it is usually called, the United Provinces of Rio de la Plata; and on the Pacific Ocean, Chili. In the central Pacific part, spreads Peru and Bolivia. The vast eastern cape terminated by St. Roque, and great part of the basin of the Amazon, are occupied by the Empire of Brazil.

The Republic of Colombia extends from S. lat. 6° 40′ to N. lat. 12° 21′, and in long. from 4° 20′ W. to 21° 13′ E. from Washington City. The outlines, according to Tanner's map of that republic, commence in North America, at the Bay del Dragon of the Caribbean Sea, and from thence follows the coast of that sea, and of the Atlantic Ocean, about two thousand miles. Across the peninsula from the Bay del Dragon to that of Dulce is about 100 miles. At the latter indenting of the Pacific Ocean begins a second line of sea coast stretching 1400 miles, and terminating at the mouth of the little river Tumbez, S. lat. 3° 50′. The land boundary, if we begin the survey on the Pacific, will extend up the Tumbez river 30 miles, from whence inflecting to S. S. E. along a ridge of the Andes 160 miles to the head of the small river Chotu, and down that stream 50 miles to its influx into the Amazon. Thence up the Amazon 50 miles to the village of Balzas. At the latter place abruptly turning to nearly E. crosses the main ridges of the Andes, 250 miles to the right bank of the Ucayale river, and down that stream 100 miles. Thence inflecting to nearly N. E. 300 miles again reaches the Amazon at S. lat. 4° and 7° E. from Washington. This great river forms the boundary 400 miles, to the inundated tract formed by its junction with a north-western branch the Jupura. Now leaving the Amazon, and following the Jupura 100 miles, turns to nearly north 120 miles to the Rio Negro, which crossing and thence following the windings of the small river Calaburis 150 miles, reaches an interior chain, the Sierra Turaguaca. Following the dividing ridge of the waters flowing into the Amazon from those entering the Orinoco and Essequibo 800 miles, reaches the extreme eastern extension of the republic. Turning by an acute angle to the north-west, 300 miles, intersects the Essequibo near its junction with the Repumunuri, and again down the former to the influx of the Cuyuni 150 miles. Following the Cuyuni, about 20, and thence by a curve of 100 miles in a northerly direction, reaches the Atlantic Ocean at the mouth of the Poumaron river.

Within the lengthened outline of 6580 miles is included an area of 1,180.000 square miles, including the entire basins of the Orinoco and Magdalena, and 412,000 in the north-western part of that of the Amazon, with the narrow but very important slopes along the Pacific, Carribbean, and Atlantic coast.

The whole territory of Colombia is divided into twelve departments: Istmo, Magdalena, Zulia, Venezuela, Maturin, Cauca, Cundinamarca, Boyaca, Orinoco, Guyaquil, Equador, and Assuay.

Istmo is the north-western department, and lies in North America, along the narrowest part of the isthmus, uniting the two continents, whence its name. It extends in nearly an east and west direction, from the meridian of Washington to 6° W. Central lat. 8½° N. Including the two provinces of Veraguas and Panama, Istmo embraces a superficies of 24,300 square miles; length from west to east 400, and mean breadth a small fraction above 80 miles, population 100,085. The capital Panama, containing a population of 9000, stands at 9° 01′ N. lat., long. 2° 31′ W. from Washington City.

Magdalena, comprising an area of 53,400 square miles, and subdivided into the provinces of Carthagena, Mompox, Santa Marta, and Rio Hacha, lies along the Caribbean Sea, from the mouth of the Atrato, to the Gulf of Maracaibo, deriving its name from the Magdalena river, which disembogues itself into the Caribbean Sea near the middle of the department. Cape Falsa, in the province of Rio de la Hacha, is the extreme northern point of the continent of South America, at N. lat. 12° 21′, from whence the department stretches inland to the south-west, and up the Cauca branch of Magdalena to N. lat. 7°, having a length from north-east to south-east of about 500 miles, and mean breadth of 107 nearly; population 176,983. The capital, Cartagena, at N. lat. 10° 24′, long. 1° 26′ E. from Washington City, is situated on an island formed by the two main outels of Magdalena river, and contains 15,000 inhabitants.

Zulia is subdivided into the four provinces of Maracaibo, Coro, Merida, and Truxillo, encircling the Lake of Maracaibo. The length of this department, following the periphery of the circle, is a little above 500 miles, having an area of 29,100 square miles, the mean breadth is a small fraction above 58 miles; lying between 8° 21′ and 12° N. and in long. from 4° to 8° 30′ E. The department of Zulia is formed from the opposing slopes of a valley between the Sierra de Perija, and the mountain chain called Paramo de la Rosa, with the Lake of Maracaibo occupying the lower part of the valley; and having the department of Magdalena west, and that of Venezuela east. Population 43,700.

Venezuela, containing the provinces of Carabobo and Caracas, with a superficial extent of 43,700 square miles, and a population of 326,840, is perhaps the most important section of the Republic of Colombia. Having the department of Zulia west, and Cumana east, fronting on the Caribbean Sea, and extending inland to the Orinoco river, the department of Venezuela is favourably situated for foreign and domestic commerce. As a natural section this department is remarkable, since though stretching along the Caribbean Sea upwards of 220 miles, the slope is inwards towards the Orinoco. The city of Caracas, distant only 8 direct miles from the sea coast, is elevated above its surface 2860 feet, and the sources of the confluents of Orinoco rise within forty miles of the waters of the Atlantic. This department extends from 7° 30′ to 10° 40′ N. lat. and in long. from 7° 05′ to 11° 35′ E. from Washington City. The capital city, Caracas, situated in a mountain valley, at 10° 31′ N., long. 9° 51′ E. from Washington, contains a population of 28,000.

Maturin comprises the three provinces of Margarita, Barcelona, and Cumana, having the Caribbean Sea north, the Atlantic Ocean north-east and east, the Orinoco river south, and Venezuela west; greatest length along the Orinoco 400 miles, and embracing a superficial area of 48,600 square miles; the mean breadth is a small fraction above 121 miles. Extending from 7° 45′ to 11° 10′ N. lat. and in long. from 11° to 16° 45′ E. from Washington City, Maturin contains the great Delta of the Orinoco, a river border along that stream of 400 miles, and an oceanic front of 700 miles. Though the original discovery of Columbus, the region contiguous to the lower Orinoco is yet very thinly peopled. Maturin on 48,600 square miles, contains but 86,017 inhabitants, or not two to the square mile; and of this moderate population, the three capitals, Asuncion of Margarita, Barcelona of the province of the same name, and Cumana of Cumana comprise 14,500. The city of Cumana is the capital of the department, and stands on the Gulf of Cariaco at N. lat. 10° 25′, long. 12° 47′ E. from Washington City; population 7000.

Cauca is the department which unites the two continents of North and South America, and stretching along the Pacific coast from the mouth of the Atrato 500 miles, comprises the four provinces of Choco, Popayan, Buenaventura, and Pasto. Having a superficial extent of 53,600 square miles, the mean breadth is about 107, with a population of 149,324. The very remarkable river Atrato, flowing into the Gulf of Darien, has its source and entire course in the province of Choco of this department, and affording a navigable channel, connected with the small river St. Juan of the Pacific, by a short canal, goes far to demonstrate that there exists no real connexion between the mountains of the two continents. The city of Popayan, N. lat. 2° 26′, and in long. 0° 19′ E. from Washington City, is elevated above the oceanic level 5,825 feet; and the city of Pasto, at N. lat. 1° 13′, and in long. 0° 22′ W. from Washington City, is elevated 8575 feet above the Pacific Ocean. Far above the region of epidemic fevers, and elevated to that of European grains and fruits, the provinces of Popayan and Pasto have a climate of mildness and uniformity highly favourable to health. Pasto contains 4500, and Popayan 2500 inhabitants. These high tropical vallies of the Andes are amongst the most desirable parts of the habitable earth, where the soil admits cultivation; but the arable land being of small extent when compared with the entire superficies, comparative population will be always restricted. There does not any where else exist a greater difference in the atmospheric phenomena than does between the two provinces of Buenaventura and Choco, and the contiguous provinces of Popayan and Pasto. The former in particular is a narrow slope along the Pacific falling rapidly from the Cordillera de Sindagua, between 1° and 4° north, with a climate of unequalled heat, humidity, tempest, and noxious insects.

Cundinamarca, east from Cauca, and stretching in a direction of nearly north and south between 8° 35′ N. and 0° 40′ S. comprises the four provinces of Antioquia, Mariquita, Bogotà, and Neiva, or Neyva. With a superficial extent of 76,600 square miles, and length of 650, the mean breadth is about 118 miles. This lengthened department unites the basins of the Magdalena and Amazon; the southern province of Neyva being in great part drained by the sources of the rivers Negro and Jupura, whilst the provinces of Bogotà, Mariquita, and Antioquia, are watered by the Cauca and Magdalena. The city of Medellin in Antioquia, 6° 13′ N. lat., long. 1° 15′ E. from Washington City, stands upon a site elevated above the ocean 4847 feet; the city of Neiva, capital of the province of that name, at 3° 07′ N., long. 1° 31′ E. from Washington City, is elevated 1310; La Honda, the capital of Mariquita, at 5° 10′ N., long. 2° 04′ E. the lowest of the four capitals of the department, is elevated 640 feet above the ocean level, whilst Bogotà, the capital of the whole department, at lat. 4° 36′ N., long. 2° 44′ E. from Washington City, rises to 8413 feet above the Pacific. Neiva and la Honda are both on the banks of the Magdalena, the former lower down the stream, 143 minutes of latitude, and by the intermediate fall of 660 feet, showing the very rapid descent of the country. Here, as in many other parts of tropical America, near the Pacific coast, the extremes of climate and vegetable production exhibit the most rapid transition: the burning sea coast, covered with a tropical vegetation, is bordered inland by mountain plains covered with wheat and other Cereal gramina; and palms are succeeded by the apple. These contrasts are peculiarly striking between the sea borders of Buenaventura and Choco, and the plain of Bogotà. The latter expanse, furrowed by the Magdalena, spreads between the Sierra de Quilidio, and the bleak mountain plateau, Paramo del Chigasa, with a breadth of 100 miles, having a remarkable resemblance to the valley of Mexico, with the exception that the lakes of Bogotà have disappeared. This valley is again rendered interesting from containing near the capital, the great cataract of Tequendama, and the natural bridge of Icononza. The population of Cundinamarca amounts to 391,426, of which 188,695 are in the province of Bogota.

Boyaca, extending from 1° 40′ S. to 8° 40′ N. lat. and in long. from 2° 35′ to 9° 10′ E. of Washington City, comprising 195,000 square miles, occupies part of an immense inclined plane, falling by a very slow declivity eastward from the Andes, and the three provinces of Pamplona, Socorro, and Tunja in the basin of Magdalena. Indeed, the extreme northern angle of the department and of the province of Pamplona, is drained by the river Zulia of lake Maricaibo. Stretching thence to the river Caqueta beyond the equator, this extensive department is traversed by the Apure, Casanare, Meta, and Guaviare, branches of the Orinoco; and by the Negro, Guapes, Apuapures, and Caqueta, confluents of the Amazon. The three north-western provinces, Pamplono, Socorro, and Tunja, lying between the eastern chain of the Andes and the river Magdalena, comprise a territory of 250 miles from S. W. to N. E. with a mean breadth of 100 miles, or 20,000 square miles, is a continuation of the great plain of Bogotà, and differs in every physical feature from the much more extended region east from the Andes. Of the entire population of 409.921, there exists 390,839, on the 20,000 square miles we have designated. If the extent of the province and the tabular numbers on Tanner's map are correct, Tunja, with a superficies of 6000 square miles and 189,632 inhabitants, is one of the best peopled parts of the republic of Colombia. From this productive and cultivated tract we pass the Andes, and enter on the almost interminable plains and deserts of Casanare, where on 175,000 square miles we find only 19 082 inhabitants. Over much of this waste spreads a plain, where rises not a hill or rock; the earth at unequal distances exposes shattered horizontal strata, something more elevated than the adjacent country. The appearance of these plains change with the seasons. After the periodical rains, one wide spreading verdant turf appears like an ocean; but with the dry season vegetable life languishes and dies, and leaves the face of Casanare a Lybian desert. Advancing towards the central parts of the basin of the Amazon, the steppes, Llanos (*plains*) are followed by forests still more desolate and dreary. At long intervals on the Llanos, human and civilized habitations have been made, but in the deep woods of the Amazon, the most loathsome reptiles hold sway. Tunja is the capital.

Orinoco, sweeping over 332,000 square miles, fills the space between the departments of Zulia and Boyaca, and the Atlantic Ocean, and is subdivided into the three provinces of Varinas, Apure, and Goyana. Bounded by the Orinoco to the south-east, the plains of Casanare south, the Sierra de Merida, or provinces of Pamplona, Merida, and Truxillo north-west, and the provinces of Carabobo and Caracas north-east; and embracing an extent of about 30,000 square miles, the two provinces of Varinas and Apure, contain 109,512, out of an entire population in the department of 125,822, leaving 16,310 inhabitants on upwards of 300,000 square miles, or above 18 square miles to a human being. The uninhabited part of Orinoco, between the Orinoco river and the Sierra Paracaina, and an extension on both banks of the Rio Negro, and stretching to the Jupura, nearly to two degrees of south latitude, is a desolate but very interesting portion of the habitable earth. It is in this region at N. lat. 3° 8′, long. 10° 38′ E. that the inland communication between the Orinoco and Rio Negro offers an interior natural channel, connecting two rivers of the first order, upwards of 600 miles from the nearest ocean. This great uninhabited tract gains a certain degree of importance also from its vastness, and from the reflection that a civilized population is slowly penetrating and removing its solitudes. Angostura the capital, otherwise called St. Tomas, is situated on the right bank of the Orinoco, at N. lat. 8° 8′, long. 13° 1′ E. from Washington City; population 4000.

Guayaquil, to survey this comparatively small but more cultivated department, leads us again to the shores of the Pacific. With an extent of 14,200 square miles, the department of Guayaquil is subdivided into two provinces, Marribi and Guayaquil proper, with an aggregate population of 73,488. Though fronting on the great ocean 450 miles, except Guayaquil river there is no great commercial entrance into this department. Compared with the adjacent provinces of Chimborazo and Pichincha, Guayaquil is depressed to almost the ocean level, and lying between 4° 21′ S. and 1° N. lat. is exposed to a burning sun twice annually. The river of Guayaquil rises near the equator, and flowing south to 2° 12′ passes the port and city to which it gives name, and opens into a wide gulf round the island of Puna. The eastern recesses of this gulf are about 30 miles from the sources of the Rio Santiago branch of the Amazon, a fact in physical geography demonstrating the very rapid acclivity of the Pacific slope of South America. The city of Cuenza on the eastern slope of the Andes, at a distance of scarce 30 miles, rises above the level of the gulf of Guayaquil 8632 feet; or almost 288 feet per mile. The city of Guayaquil, the capital of the department, stands on the right bank of the river of the same name, at 2° 12′ S. lat., long. 3° 2′ W. from Washington City. The environs, according to Humboldt, are highly majestic, from the variety and magnitude of its vegetable products.

Equador, or the Department of the Equator, is amongst the most elevated habitable regions of this planet. Extending from 3° 5′ S. to 1° 15′ N. lat. and in long. from 1° 30′ E. to 2° 40′ W. this department is subdivided into three provinces, Pichincha, Ymbabura, and Chimborazo. Nature has here not sported, but exerted a strength at the effects of which the human mind shrinks with dread, whilst enchained by admiration. The Andes, divided into three separate chains in Cauca and Cundinamarca, gradually approach in the province of Pasto, and apparently merge in that of Ymbabura. But though apparently confounded, two chains remain distinct, with a very elevated intervening valley raised above the ocean from 8800 to 9500 feet. Colossal volcanic summits rise in symmetrical opposing lines, which covered with eternal snows, served as signal points to the French mathematicians in the measurement of an equatorial degree. Cotapaxi, Antisana, and Cayambe Urcu, range along the eastern, whilst Chimborazo and Pichincha crown the western chain. On the great table land between these gigantic mountains, where the barometer stands at 21.3, we find Quito, 0° 13′ S. lat. with 52,000 inhabitants, standing 9540 feet above the level of the Pacific; Ibarra, 0° 20′ N. lat. at 7591 feet of elevation, and 12,000 inhabitants; Riobamba, 1° 41′ S. lat. at 8441 feet, and 16,000 inhabitants; Loxa, 3° 58′ S. lat. at the height of 6765 feet, and 10,000 inhabitants; and Cuenca, 2° 55′ S. lat. at 8632 feet, and 25,000 inhabitants. The habitable plateau in the provinces of Chimborazo, Pichincha, and Imbabura, is 240 miles in length, with a mean breadth of 30, or 7200 square miles; on which area there is already a population of nearly 300,000 inhabitants, upwards of 41 to the square mile. It is on this aerial plain that the traveller and inhabitant, under and contiguous to the equator, range amid the mingled vegetation of the most distant climes. The lama is seen sporting in the same pastures with the sheep of Asia and Europe. The human being feels invigorated in an atmosphere, nearly four times more elevated than the chains of the Appalachian system. When we read, however, of mountains rising above the ocean to a height from 15,000 to 21,000 feet, the effect on our minds is very different from what a view of the same summits would produce when actually seen from the equatorial plateau. Already elevated to 8000 feet, such a system of mountains as that of the Pyrenees, would be merged in the plain of vision, and even Chimborazo is depressed more than one-third of its absolute height.

The province of Ymbabura, confined to the central plain, is more than semicircled by that of Pichincha, which latter rising from the sand and rocks of the Pacific, sweeps over the summit and plain of the Andes, far down the Isa, Napo, Piguena, and other branches of the Amazon combining in a length of 280 miles, all the climates, and admitting a large portion of all the vegetables of the earth. Quito, the capital of the province of Pichincha, and of the whole department of the Equator, stands on a site too uneven to admit, says Malte Brun, of the use of carriages. The latitude and height of this city have already been noticed. Though so near the equator, Fahrenheit's thermometer ranges between 40 & 61, but contrary to what might be expected, the seasons of different years vary greatly in mean and relative temperature The whole adjacent country is very subject to earthquakes; one of which, attended with peculiar destructive effects, occurred February 4th, 1797. But amid the revolutions of their turbulent atmosphere, and treading on ground so liable to convulsion, the people of Quito are admired by every traveller for urbane, kind, lively, and hospitable manners.

Assuay, the extreme southern, or rather south-western department of Colombia, sweeps eastward from the highest summits of the Andes, from within 20 miles from the Pacific Ocean, and 3° 10′ W. from Washington, to the alluvial junction of the Amazon and Jupura, 11° 40′ E. from Washington. Extending from west to east through nearly fifteen degrees of longitude, between latitude 6° 35′ S. and 0° 50′ N., this extensive region embraces an area of 251,700 square miles, with, however, only 127,900 inhabitants, or about one human being to two square miles. It is subdivided into three provinces of very unequal extent; Cuenca, 170 by 70 miles, and with an area of 11,900 square miles, containing 76,423 inhabitants; Loxa, 100 by 60 miles, and on 6000 square miles, contains 34,471 inhabitants. The residue of the population, 16,000, is seated on the western border of the immense province of Jaen de Bracamores. Indeed, the inhabited part of Assuay is in great part confined to the elevated table land of the Andes; Cuenca, capital of the province of the same name, rises above the Pacific 8,632 feet, with 25,000 inhabitants, and Loxa, capital of the province of Loxa, contains a population of 10,000, who exist 6765 feet above the oceanic level. From this temperate region, Assuay falls in a lengthened inclined plane of 1000 miles. The rivers Amazon, Gualaga, Ucayale, and Javari, pour their great volumes from the south-west into Assuay, which is again furnished by the minor, though still large streams, of Santiago, Pastaca, Piguena or Tigre, Napo, Putumayo or Isa, and is limited north-east by the Jupura. The latter rivers have their sources on the table land of the Andes, but traverse the great plain which spreads along the eastern border of that system of mountains. The white or Spanish inhabitants occupy the plateau of the Andes, whilst the alluvial plains are yet in possession of the aboriginal Indians.

We have now taken a survey of the widely extended Republic of Colombia, as much in detail as the nature of our work would admit. The subjoined summary will give the reader a condensed view of the extent and relative position of this large section of South America.

Summary Table of the departmental Subdivisions of the Republic of Colombia.

Departments.	Area in Square Miles.	Population.	Capitals.	Population.	Latitude.	Longitude.	Altitude in feet.
Istmo, - -	24,300	100,085	Panama,	9,000	9° 01′ N.	2° 31′ W.	
Magdalena, -	53,400	176,983	Carthagena,	15,000	10 24 N.	1 26 E.	
Zulia, - -	29,100	120,960	Maracaibo,	20,000	10 41 N.	5 35 E.	
Venezuela, -	43,700	326,840	Caracas,	28,000	10 31 N.	9 51 E.	2,860
Maturin, -	48,600	86,017	Cumana,	7,000	10 25 N.	12 47 E.	
Cauca, - -	53,600	149,374	Popayan,	8,000	2 26 N.	0 19 E.	5,825
Cundinamarca,	76,600	391,426	Bogota,	38,000	4 36 N.	2 44 E.	8,818
Boyaca, - -	195,000	409,921	Tunja,	16,000	5 16 N.	3 10 E.	
Orinoco, -	332,000	125,822	Angostura,	4,000	8 08 N.	13 01 E.	
Guayaquil, -	14,200	73,488	Guayaquil,	20,000	2 12 S.	3 02 W.	
Equador, -	58,700	307,614	Quito,	52,000	0 13 S.	1 45 W.	9,540
Assuay, - -	251,700	127,894	Cuenca,	25,000	2 55 S.	2 16 W.	8,632
Total,	1,180,900	2,396,404					

In relative position, and in the accuracy of information in regard to the local subdivisions, the Empire of Brasil, or Brazil, follows Colombia. After Russia and China, the Empire of Brasil is the most extensive political subdivision of the earth, and the most extensive continuous body of productive soil ever united under one sovereignty. Excluding the Banda Oriental, Brazil stretches along the Atlantic Ocean from Cape Orange, N. lat. 4°, to near the mouth of Rio Grande, S. lat. 32°; and from east to west, from Cape San Roque, long. from Washington 44° E. to the mouth of the Javari river, long. 7° E. from Washington. Extending through 36 degrees of latitude, and 37 degrees of longitude, forming a trapezium, approaching to a square of 2500 miles each side. Within this expanded perimeter, is included between three and four millions of square miles. Having an ocean border of 3900 miles, indented by small but convenient bays, and by the unequalled Amazon, and many other rivers. It would not, it is probable, be infringing the truth to say, that every 20 miles of the whole of the Brazilian coast would average a river.

The eastern part, where the civilized settlements are chiefly made, is broken and even mountainous, but advancing into the interior, over the basin of the Amazon, the surface is comparatively level. Much is low, alluvial, and periodically overflowed. It is deceptive, however, to attempt to give any general character to regions, exceeding the superficies of all Europe, and whose secondary provinces are individually more extensive than Germany, France, or Spain. Brazil is nevertheless naturally divided into two unequal physical sections. A not very well defined, nor elevated system of mountains stretches southward from the estuary of the Amazon, until merged in the Atlantic Ocean, S. lat. 28°. Eastward from this system, spreads a triangular slope of 2000 miles base and 1000 perpendicular, containing about 1,000,000 square miles. This slope sustains, with the exception of some settlements along the Amazon, and other interior streams, the improved part of the empire, but not more than one third part of its territory. Passing from the Atlantic slope of Brazil, an almost interminable interior opens. In our general view of South America, the great interior valley was noticed. The central parts of this valley are included in Brazil. Without any apparent regular elevation that could influence the courses of the rivers, the waters of the Brazilian valley are discharged northward, towards the Amazon, or southward into the basin of the Rio de la Plata. The Tocantin, Xingu, Tapajos, Madeira, Purùs, and Jutay, are only the principal tributaries of the Amazon, which traverse Brazil. The southern provinces, Rio Grande, and St. Paul's, and much of Minas Geraes, Goias, and Matto Grosso, are drained by the innumerable branches of the Parana and Paraguay.

The Atlantic slope of Brazil has been examined by several scientific travellers, but the central regions on both sides of the Amazon have been but imperfectly explored. The connexion between the Orinoco and Amazon basins, by the Rio Negro, noticed in our survey of Colombia, was only recently determined. Sufficient is known, however, to enable us to complete the general sketch of Brazil by including a territory north of the Amazon, comprising the lower part of the valley of the Rio Negro, and an additional tract of 800 miles in length, reaching from the mouth of the latter stream to the Atlantic Ocean.

The civil divisions of Brazil, perplexing to the natives, are inexplicable to strangers. In the Spanish and Portuguese American colonies, there were civil and military provinces, with different names, and sometimes conflicting limits. The subdivision of Brazil into captain generalships, is best known, and is as follows:

Rio Janeiro, containing the capital of the empire, lies along the Atlantic Ocean, from the river Doce, to the Baua Canressu. It is four hundred miles in length along the ocean, but in no place much exceeds one hundred inland, and does not average above 80 miles in width. This province, when under Portugal, was entitled and ruled as a viceroyalty, is traversed from south-west to north-east by a chain of secondary mountains, and is a high, broken, fertile, and healthy country. Rio Janeiro, the capital of the province, and of the empire, stands on a fine bay of the Atlantic Ocean, at S. lat. 23°, and long. 33° 14′ E. from Washington City. The population in 1817, was by Malte Brun computed at 110,000; the amount at present (1829) is no doubt considerably augmented.

Minas Geraes has a front on the Atlantic Ocean from the mouth of the Doce to that of the Pardo river, 450 miles, and spreads inland, nearly semicircling Rio Janeiro; having Bahia north, Goias west, and St. Paul's south-west; lying between S. lat. 15° and 22° 40′; length 600 miles, and mean breadth about 300; superficies 180,000 square miles. The south-western part of Minas Geraes, is drained by the eastern sources of the Parana; the western by the St. Francis; and the eastern by the Doce and other minor streams. It is a hilly, in many parts a mountainous country, with a population perhaps amounting to 500,000, amongst whom mining has superceded or retarded agriculture in a soil and climate where vegetation demands slight labour, and where the range of vegetable products is indefinable. This province is divided for civil purposes into the *Comarcas*, or districts of St. Joao del Rey, Sabara, and Cerro del Frio.

St. Paul's, or San Paulo, is the south-west captain generalship of Brazil, and follows Rio Janeiro, and Minas Geraes, and lying between the Atlantic Ocean and river Parana, having a front on the Atlantic Ocean of 400 miles; greatest length from north-east to south-west 560 miles, with a mean breadth of 300; area 168,000 square miles. With the exception of a narrow strip on the Atlantic Ocean, St. Paul's is an inclined plane sloping to the north-west, and down which numerous confluents of the Parana are precipitated, and flow, not towards the contiguous ocean, but directly towards the central parts of the continent. The dividing ridge between the short Atlantic rivers and the sources of the Parana, is part of the Brazilian system of mountains, already noticed, and which, in St. Paul's, rise from the margin of the Atlantic. The city of St. Paul's, though not in a direct line, 40 miles from the ocean, is drained by a tributary of the Parana. The mountains rise abruptly from the ocean to about 6000 feet, and slope by gentle ascent inland. The city of St. Paul's, connected with its port Santos by a paved road formed with great labour and expense over the mountain gorges, contains a population of 30,000 souls. Its elevated position, and latitude almost exactly under the southern tropic, give to this city a peculiarly temperate climate.

The whole of the province of St. Paul's, lying between S. lat. 19° and 25° 40′, contains a population of about 220,000 souls, engaged in agriculture and mining. Such a population, however, when viewed comparatively, shows a country where civilized settlement is only commenced, though, perhaps of all the original establishments in America, the first settlers of St. Paul's were amongst the most active and intelligent.

Rio Grande, deriving its name from one of the numerous rivers of South America bearing that title, is the southern province of Brazil, having the Atlantic Ocean south-east, St. Paul's north, Banda Oriental south, and Uruguay west, with a front of upwards of five hundred miles on the Atlantic Ocean. The south-western boundary of Rio Grande is of great political consequence, as it is the limit between the empire of Brazil, and Banda Oriental. On the map published in London in 1825, and which forms the frontispiece to the "Account, Historical, Political, and Statistical, of the United Provinces of Rio de la Plata, the limit between the Banda Oriental and Rio Grande is thus traced: commencing on the Uruguay river, at its junction with the Ubicui, and following the latter to its source; thence, by a line south-eastward about sixty miles to the source of the Yaguaron river, and thence down the latter to its entrance into the Laguna Merin. From thence to the Atlantic Ocean, a distance of about 40 miles in a direct course, the boundary is not either etched or coloured, but most probably was intended to follow the Laguna Merin, its outlet, into the Laguna Patos, and thence to the Atlantic, by the mouth of the Rio Grande river. The boundary thus traced deserves particular attention, as the original of the map was drawn at Buenos Ayres, and of course acknowledged by the authorities of the United Provinces of Rio de la Plata. On Tanner's map of South America, the limit is drawn across the peninsula, between the Laguna Merin and the Atlantic Ocean, reaching the ocean about 20 miles north of a place named on the map, Marco del Limite.

The physical features of the province of Rio Grande are in a peculiar manner varied and interesting. The southern part is composed of that remarkable basin from which the province derives its name, and which has already been noticed in our general view of South America. The western and north-western sections slope towards the Uruguay and Parana rivers, whilst the north-eastern are composed of a very narrow mountainous slope along the Atlantic Ocean. The whole province extends from the river Iguacu, flowing into the Parana, 25° 20′, to the river Yaguaron, S. lat. 32° 40′; long. 25° E. from Washington City, dividing the province into two very nearly equal sections. Its extent in square miles is about one hundred thousand, having a length from north to south of upwards of five hundred, with a mean breadth of two hundred miles. Rio Grande, the capital, stands on the very singular outlet of the river of that name. It is a seaport, but the shallowness of the water on the entrance, the violence of the currents, and quicksands, render the entrance dangerous for vessels drawing more than ten feet, though within the bar there is a safe anchorage, and depth of water for any ship, of whatever draught. It is along the Rio Grande that the population is chiefly distributed. "A circuit," says Malte Brun, "of twenty leagues, is supposed to contain a hundred thousand inhabitants."

The small island of St. Catherine, opposite the north-eastern coast of this province, and the adjacent shores around the city of Rosario, have been much celebrated for fertility of soil and picturesque scenery. The centre of the island is in S. lat. 27° 30′, but the mountainous elevation of the coast lowers the temperature so much, as to give to the seasons a mean heat suitable to a much higher latitude.

Bahia lies between the Atlantic Ocean and the river St. Francisco, and has Minas Geraes south, Maranham west, and Pernambuco north. It derives its name from that of the great Bay of Todos os Santos, or All Saints Bay, on which, or rather on a peninsula between it and the Atlantic Ocean, stands the capital, San Salvador do Bahia, with a population, it is probable, of one hundred thousand people. The peninsula is narrow, but receding from the southern point northward, rises to about six hundred feet above the ocean and bay. The city ranges nearly four miles along this neck. The point or ship entrance is at S. lat. 12° 50′.

Under the name of Bahia, are included some comarcas or districts not directly connected with its administration. The district of Sergipe del Rey lies between the river St. Francis and Rio Real, and north-east from Bahia. Ilheos extends along the Atlantic Ocean from the Rio dos Contas to the Pardo, and of course between Bahia and Minas Geraes. However, for the purposes of general and physical geography, the bounds of Bahia may be viewed as follows: along the Atlantic Ocean, four hundred miles, from S. lat. 11° to 15°. The river St. Francis curves round this province on two sides, and forms a natural boundary upwards of seven hundred miles. On the south it is bounded by the Pardo, and a line, perhaps imaginary, thence to the right bank of St. Francis. Length from south-west to north-east about five hundred, and mean breadth two hundred miles, with an area of one hundred thousand square miles. Situated entirely within the torrid zone, and greatly diversified in surface, the productions of Bahia are numerous and valuable. Indigo, tobacco, rice, sugar, &c. are, with Brazil wood, its most common staple. Coffee is also cultivated, as are innumerable fruits and grains.

Pernambuco is remarkable as forming the most eastern part of the continent of America. It is bounded south-east, east, and north-east by the Atlantic Ocean; south by the river St. Francis, and west by a chain of mountains called the Sierra de Pianhi. Extending from south latitude 3° to 11°, and along the Atlantic Ocean by an immense sweep, from the village of Santa Cruz, on the small bay of Camosin, upwards of one thousand miles to the mouth of the St. Francis. It approaches to a square of four hundred miles each side, and comprises an area exceeding one hundred and sixty thousand square miles. A part of the coast only, however, is inhabited, but that contains the capital. This singular city is composed of two towns, Recif, or Pernambuco proper, and Olinda. The former is built on two islands, and the latter, three miles distance, on an eminence. Joint population sixty-five thousand. Lat. 7° 20′ S., long. from Washington City, 37° 10′ E. The interior of Pernambuco is singular as a physical section of South America, from the character of its rivers. Those flowing into the Atlantic are extremely limited in their length of course, whilst the interior appears a wide desert, entirely devoid of streams of any kind, giving to its map an appearance similar to that of Arabia. From the first establishment of the Portuguese on this part of America, the principal staples of Pernambuco have been cotton, sugar, and Brazil wood.

Ceara or Seara, and Paraiba, are districts included within Pernambuco, and dependent on the military governor thereof, but are independent as respects their civil jurisdiction.

Maranham follows Pernambuco, to the north-west, and includes the district of Pianhy. Taken in its most extended limits, this province stretches from the estuary of the Turuiassu river, S. lat. 1° 10′, to the northern boundary of Minas Geraes, S. lat. 14° 25′, or through upwards of thirteen degrees of latitude; having the Atlantic Ocean north; Pernambuco east; the river St. Francisco, or Bahia, south-east; Goias south-west, and Para north-west. Length from north to south above nine hundred miles, with a mean width of at least two hundred and eighty miles, and an area, at the lowest estimate, of two hundred and fifty thousand square miles. In regard to actual settlement by a civilized people, the extended region under the general name of Maranham, is nominal in great part. The comarca, or district particularly called by the title of Maranham, from the name of the capital, is small, but important from its staple productions, which to many more, may be named annati, capsicum, ginger, and pepper. The city of Maranham, with a population of thirty thousand souls, stands on an island at the mouth of the Pinare river, S. lat. 2° 28′, long. Washington City, 32° 56′ E.

The seven provinces, or captain generalships we have surveyed, stretching from the vicinity of the equator to S. lat. 32°, and containing an aggregate superficies of nine hundred and ninety thousand square miles, do not contain, when thus taken together, the one-third part of the Brazillian territory, and we now proceed to notice the still more extended, but less known tracts of South America.

Goias, as delineated on Tanner's map of South America, stretches from the confluence of the Tocantin and Araguay rivers, S. lat. 6°, to the junction of a small river named Pardo, with the Parana, S. lat. 21° 40′; having Matto Grosso west; Para north-west and north; Maranham north-east; Minas Geraes south-east; and St. Paul's south. Length one thousand and eighty miles, and mean width exceeding two hundred miles, with an area of at least two hundred and twenty thousand square miles. This very extensive province is bounded on the west by the Araguay in the entire length of that river, and contains nearly the whole valley of the Tocantin. The southern part is drained by the extreme northern tributary of the Parana, the Paranaiba, which has interlocking sources with those of the Tocantin and Araguay. The province of Goias, is obviously from the courses of its rivers, composed of two unequal inclined planes, sloping north and south from a table land between 16° and 18° S. lat. This plateau must be of considerable elevation, as a chain of mountains called the Cordillera Grande, is drawn from it on Tanner's map, and extends to the junction of the Araguay and Tocantin, through eleven degrees of latitude.

Goias is as yet thinly peopled, and but very imperfectly explored. The settlements are principally on the higher branches of the Tocantin and Paranaiba. Villa Boa, the capital, stands in a mountain valley on the source of a branch of the Vermelho river, at S. lat. 16° 12′, long. 28° 56′ E. from Washington City, about 700 miles N.W. and directly inland from Rio Janeiro. The population of Goias is too much scattered, to be sufficiently well ascertained in regard to number, to admit even an approximate enumeration.

Matto Grosso, still more extensive and still worse explored, lies west and south-west from Goias, and extends from S. lat. 9°, to the tropic of Capricorn, S. lat. 23° 50′. On the southern boundary, this province fills the space, about 250 miles, between the Parana and Paraguay; and on the northern limit sweeps upwards of one thousand miles from the Araguay to the Madeira. At the broadest part, S. lat. 10°, this province extends about 1100 miles from east to west; its greatest length from the angle on the Paragnay, to that on the Madeira, above twelve hundred miles. The area falls little, if any short of 600,000 square miles, or between nine and ten times the extent of Virginia. With our imperfect knowledge of its local features, it would be mere idle presumption to give a general character of Matto Grosso. It may be sufficient to observe, that the central part is decidedly a table land of considerable elevation, as from it flow, north-westward, the eastern sources of the Madeira; to the north are discharged the higher branches of the Tapajos and Xingu; the waters of the Rio das Mortes, a branch of the Araguay, flow eastward, whilst the numerous and most northerly confluents of the Paraguay fall to the south down the higher rim of the basin of Rio de la Plata. The table land of Matto Grosso is, in fact, a continuation of that of Goias.

Villa do Cuibabu, the capital of Matto Grosso, is situated on a river of the same name, at S. lat. 15° 20′, and long. 21° E. from Washington, about 1100 miles north-west by west from Rio Janeiro, and 1200 a little east of north from Buenos Ayres.

If we add the combined extent of Goias and Matto Grosso, 820,000 square miles, to that of the Atlantic provinces previously noticed, 990,000 square miles, we have an area of *one million eight hundred and ten thousand square miles*, a superficies exceeding that of the Roman empire under Trajan and the Antonines, and far exceeding China proper, or European Russia, and yet we have not included perhaps one half the Brazilian territories. We have now to launch into the central regions of Amazonia.

Para reaches from the sources of the Branco branch of Rio Negro, in the mountains of Guyana, N. lat. 4°, to Fort Principe de Beira, on the Madeira, S. lat. 12°. In longitude this province extends from the mouth of the river Juriassu, 32° E. from Washington City, to the sources of the Javari, 5° E. from the same meridian. Length from east to west, 1830 miles. The mean width must exceed one thousand, with an area of 1,830,000 square miles. The main volume of the Amazon reaches Para at the mouth of the Javari, and separates Lower Peru from the dominions of Brazil to Fort St. Fernando, at the mouth of the Ica. Below the latter point, the already great stream of the Amazon enters and continues its entire course of upwards of one thousand four hundred miles in Para. Immense as is the mass of water already accumulated in the Amazon above Para, it receives in that province, beside innumerable smaller streams, the Jupura and Negro from the north-west, and from the south-west, the Jutay, Jurua, Tefte, Purùs, Madeira, Tapajos, Xingu, and Tocantin. We have already waived the attempt to give general characters to regions so immense—we may here merely observe, that it would be no hazard to pronounce Para, if all its natural advantages of tropical climate, fertility of soil, and abundance and navigable facilities of its rivers are taken into view, as the most favoured tract of comparative continuous extent on the whole habitable earth.

When we turn, however, from the features of nature to the improvements of man, we find Para, with a few detached settlements, a waste. The immense Llanos, Pampas, or grassy plains devoid of timber, so extensive along the eastern slope of the Andes, in the entire length of South America, have but a limited existence on the lower part of the basin of the Amazon. Entangled forests, with all the variety and luxuriance of a tropical clime aided by a soil exuberantly fertile, spread over Para. The hand of man can be hardly said to have attacked this world of wood. Para, or Grand Para, sometimes called Belem, a city on the right bank of the Tocantin, at its mouth, and which contains 20,000 inhabitants, is the capital, and gives political name to the province. This city stands at S. lat. 1° 30′, and long. 28° 27′ E. from Washington City.

The government or district of Rio Negro, is a comarca of Para, but the former, dependent on the military, is free from the civil jurisdiction of the latter. In Rio Negro, there has not yet risen a town deserving the name of city.

We have, as far as our materials admitted, sketched the outlines of the ten captain generalships of Brazil, and by that means given the general extent and relative situation of the subdivisions of that empire. But, for civil jurisdiction, that sovereignty is divided into comarcas or districts, in each of which there is an *ouvidor* or judge. These comarcas, where their position is actually and accurately laid down, enable us to fix real settlement much more correctly than can be done by the great military provinces. Malte Brun names twenty-four comarcas, which, as may be seen, in part follow, and in part are different from the provincial subdivisions: of these, Bahia, Porto Seguro, Sergipe del Rey, and Ilheos, are included in Bahia. The comarca and captain generalship of Rio Janeiro are commensurate, with the exception of Espirito Santo, which occupies the north-east part of the province from the river St. John. The comarcas of Ceara, Paraiba, and Pernambuco, are included in the province of the latter name. Piahu and Maranhao, are comarcas of Maranhao, or Maranham. San Paulo, Santa Catarina, and Paranagua, are comarcas of St. Paul's. Porto Seguro, Sabara, Serro do Frio, and Villa Rica, are comarcas of Minas Geraes. Rio do Frio is a comarca of Matto Grosso, on the head of the Araguay. Some other comarcas are named from the province in which they are placed, but from increase of population these judicial districts must be subject to frequent change.

The population of Brazil has been a subject of much and mere conjecture. It has been estimated from three to four millions, and may probably, if all castes are included, exceed even the latter amount. If the position of the comarcas is carefully examined on a map, it will be seen how very detached are the settlements. Brazil, separated from Portugal, has become a nation of America, with an unequalled extent of dominion, and must, under an even tolerable administration, advance to great power and prosperity.

The United Provinces of Rio de la Plata follow the empire of Brazil in relative position. We may remark as a curious coincidence, that in North America, the United States sweep over the great basin of the Mississippi; and in South America, the republic of Colombia embraces the Orinoco, Brazil the greater part of the basin of the Amazon, whilst the United Provinces of the Rio de la Plata are, with but partial exceptions, commensurate with the basin of the great river from which their title is derived. Thus in America, those wide natural basins, with streams flowing to single points, have already influenced the artificial outlines of new nations, and will contribute physically to unite communities morally and politically connected.

Similar to other parts of the Spanish dominions in America, the administration of the parent state gave rise to murmurs long previous to actual revolt. These murmurs rose to a storm in 1810 at Buenos Ayres, and the Platane provinces ceased to be Spanish. The revolution in that country is in fact not yet terminated, but the aspect of the provinces is sufficiently fixed to admit a geographical view; which we are enabled to take with some clearness, from the Historical, Political, and Statistical Account already noticed.

Before, however, entering on the detailed provincial survey, we may pause to examine the great confluents of the Rio de la Plata. The basin of the Plate extends from the sources of Paraguay, S. lat. 13°, to Cape St. Antonio, S. lat. 36° 40′, and what is peculiarly remarkable, its greatest breadth about S. lat. 22°, equal to 26 degrees of longitude, reaches from less than one hundred miles from the Pacific Ocean, to a still nearer approach to the waters of the Atlantic. The Pilcomayo on the west, and the Parana on the east, flow respectively towards the central parts of the continent. It is generally known that the Andes range nearly parallel to, and at no great distance from the Pacific, but it is by no means equally well known, that the corresponding Atlantic slope from S. lat. 20° to the mouth of the Rio de la Plata, is still more restricted in breadth. The latter, immediately under the southern tropic, in the vicinity of St. Paul's, is not thirty miles wide, from the shore of the Atlantic to the sources of the Tieté; and again, at S. lat. 28°, the higher branches of the Uruguay flow within 50 miles of the Atlantic waters.

The name of Rio de la Plata is only given to the bay below the junction of the Parana and Uruguay. By a misnomer, similar to what has occurred in North America with the Mississippi and Missouri, the Parana has superseded the main stream of the Paraguay. The latter rises at S. lat. 13°, interlocking sources with the Tapajos and Xingu. Augmented by numerous confluents, this river flows almost directly south to S. lat. 21° 20′, at the city of Assumption, where it receives from the north-west a very large branch, the Pilcomayo, and also from the same side, 100 miles lower, another of great magnitude, the Rio Grande, and again 50 miles still lower, loses its name by receiving the Parana. The latter takes its source in the long range of mountains situated to the north-west of Rio Janeiro, in S. lat. 21°. It is increased by uniting with the Parancuba, the Tiesse, the Paranapane, and the Curitaba. Winding to the north-west, to S. lat. 19° it receives from the north the Paranaiba, and turns to S. S. W., and continues that direction to S. lat. 27° 30′, into the Missiones de las Guarames. From this place, it begins to display its peculiar character: forming an archipelago, of an infinite number of islands, and turning west, joins the Paraguay at the city of Las Siete Corrientes. Here the Parana and Paraguay have conjointly drained at least 800,000 square miles, and the united waters under the former name, but continuing the general course of the latter, assume the grand and majestic appearance which it retains, and descending, like a fresh water sea, with a mean course south, but curving to the west, to S. lat. 34° 20′, where it receives from the N. N. E. the Uruguay, and opening into a wide estuary loses its name in that of Rio de la Plata. Without regarding partial bends, the Parana flows from Corrientes to its mouth 560 miles, receiving from the west numerous minor confluents. The Parana admits the entrance of vessels of 15 feet draught, and is navigable for those of 300 tons burthen above the city of Assumption. The various confluents are navigable to near their sources, rendering the basin of the Rio de la Plata, like that of the Mississippi, a vast expanse capable of indefinite intercommunication by water.

The Parana is subject to annual inundation. The rise begins about the end of December, some time after the commencement of the rainy season in the countries between the tropic of Capricorn and the equator; and it continues to rise, without interruption, to the beginning of April. Then, decreasing till July, with a little more rapidity than it rose, it again returns to its natural bed. The inundations are not invariable as to elevation. The average rising is about twelve feet.

The local features of soil and climate will be best seen by reference to the subjoined description of the provinces.

Buenos Ayres, from which the whole republic is often named, is the most southern and important province, and lies south-west from the great bay of Rio de la Plata and the Parana river. It is in form of a triangle, with the base from Cape St. Antonio north-west to Rosario on the Parana, and stretching inland to a rather indefinite extent. The surface to which settlements have been extended may amount to 20,000 square miles. The capital of the province and of the whole republic, the important city of Buenos Ayres, is situated on the south-western or right bank of Rio de la Plata, about 30 miles below the junction of Parana and Uruguay rivers, and at S. lat. 34° 36′ 29″, long. 18° 32′ E. from Washington City, and 58° 23′ W. from London; at an elevation above high tide in the adjacent bay of 35 Castillian, or 33⅓ English feet. As this city occupies a favourable position in the southern temperate zone of America, and as we have element derived from respectable observers on the spot, it may be well to dwell something at large on the climate and seasons of Buenos Ayres.

To the west and south the territory of Buenos Ayres is flat, forming a continued plain, which extends to the confines of the provinces of Cordova and Mendoza. These pampas, or open plains, sweep upwards of five hundred miles to the south-west from Buenos Ayres, which is in fact seated on their margin. They spread from the Atlantic Ocean to the Andes, and are parts of the same species of soil which at broken intervals skirt the eastern slope of the Andes from the Llanos of Cundinamarca inclusive, to the recesses of Patagonia. The quality of the soil is generally chalk and productive mould to the depth of three feet. Neither on the surface, nor on excavating, are stones of any kind met with. It is only at the depth of seventy-five or eighty feet that a hardened clay containing lime, and called *tosca*, is encountered. Directly north from the city is the inundated valley of the Uruguay, which rising in the Brazilian province of Rio Grande, flows first nearly west, gradually curving to south, which latter course, with a slight inclination west, it pursues from south lat. 30° to its junction with the Parana, at 34°. To the north-west, again spreads the still more extensive delta of the Parana, the whole covered with immense forests. To the north-east, beyond the bay, the surface of the Banda Oriental is high and dry, and finally to the east and south-east, opens the great bay of La Plata. From these local features, and the great difference of surface over which the various winds sweep, it is obvious that the seasons of Buenos Ayres must be liable to great and sudden revolution; and that health must be most essentially influenced by prevalent winds. This is the case, and the wind most dreaded at Buenos Ayres is that from the north. This wind is humid, at all seasons, and often attended by excessive rains. It produces laxity of the whole frame, but in a particular manner affects the head. A fact attends the north wind at Buenos Ayres, which almost uniformly precedes copious rain; objects become visible at an immense distance. La Colonia, on the opposite side of the bay, 25 miles distant, is seen under the influence of the north wind. The north-east wind, though in a diminished ratio, participates in the preceding phenomena. The south-west (*pampero*) is by far the most wholesome wind at Buenos Ayres. Its elasticity, purity, and vigour, make it desirable in all seasons, as it counteracts the humidity too prevalent in the houses. The effects produced by the *pamperos* are at once deducible to the cause, by reference to the physical geography of that part of South America, south-west from the estuary of the Plate. In summer, a breeze from the river, or from the east, is produced every evening, with the same regularity as attends those currents of air called trade-winds within the tropics. It has been observed in winter at Buenos Ayres, that often when the air in the streets is warm and bracing, it is cold, moist, and distressing in the houses. This is occasioned by the want of fires. The author, from whom these observations are extracted, observes, "Our fathers have handed down to us an absurd prejudice against fire; and the anti-philosophical and hurtful manner in which they made use of it, in open brasiers, was sufficient, by its effects, to sanction the prejudice. It is but lately, that foreigners have overcome that aversion in us to artificial heat; and their example, their good state of health, and their not suffering more than others from the commencement of cold weather, but on the contrary less, have made converts of many of the natives, who already begin to have chimneys in their habitations."

Taking a series of seasons, the general weather is found pleasant and salubrious; the aspect of the sky beautiful; the air bracing, and exciting in the human mind a confidence of health.

The barometer has risen to thirty inches, and was never lower than twenty-nine. The thermometer seldom falls even to the freezing point of Fahrenheit. A series of years, from 1817 to 1821 inclusive, give for the greatest heat, 83, 85, 85, 86, and 81, and for the greatest cold, in 1817, 28°, or four degrees below the freezing point, a very uncommon occurrence in that country.

Such is the territory and productive facilities of the province of Buenos Ayres, that under a free and liberal administration its prosperity must advance rapidly. In 1825, the city contained a population of 81,136, the country 82,080; aggregate 163,216.

The list of staples for exportation, shows, however, the very low state of agriculture. These staples are hides of horses, cows, and vicunna; sheep's and vicunna wool; horse hair and ostrich feathers; lamb, otter, chinchilla, wolf, lion, and tiger skins; tallow, beef, and last of all, wheat.

Entre Rios, or *Between Rivers*, is a real Mesopotamia, having the Parana south and west, the Uruguay east, a line from one river to the other, nearly along S. lat. 30°, of one hundred and fifty miles. From the northern boundary it extends in the form of a parallelogram of about one hundred and forty miles wide, to the confluence of the Parana and Uruguay, in S. lat. 34°. The length of its course is equal to four degrees of latitude, or 280 miles, in round numbers; superficies 39,200 square miles. No spot of all South America is more advantageously situated for agriculture and commerce, bounded as it is by two of the finest rivers of that continent. In its natural state Entre Rios was a dense forest, and so in a great measure it remains; as in 1825, the inhabitants amounted to only about thirty thousand.

Corrientes lies above Entre Rios, and remarkable as is the river perimiter of the latter, that of the former is not less so; having the Parana on the north and west, and the Uruguay east. At the north-east angle of the province the two rivers approach to within thirty miles of each other, and then recede, the Parana westward, and the Uruguay south-west. Spreading thus between those rivers, the province of Corrientes fills the space from the Parana above its junction with the Paraguay, or from S. lat. 27° 20′, to the northern boundary of Entre Rios, S. lat. 30°, forming nearly a square of two hundred miles each way; area about forty thousand square miles. This province, but little known, was one of the most early Spanish settlements on the basin of the Plate. The city of Corrientes is situated on the east, or left bank of the Parana, immediately below the mouth of the Paraguay, S. lat. 27° 26′, and almost exactly due north from Buenos Ayres; difference of lat. 7° 10′, or five hundred English statute miles.

With much resemblance to Entre Rios, the surface of Corrientes is more diversified. In the interior are many lakes, and in particular one called Ypicu, or Ybera, boasted of for the beauty of its shores. The inhabitants of Corrientes, similar to those of all other countries where the climate is mild, the soil fertile, and the population thin, are disinclined to labour. The situation of the capital is admirable for commerce, and the dense forests would be as favourable for steam-vessels, but hitherto, pastoral pursuits have been preferred. Agriculture has not been altogether neglected; sugar, cotton, and indigo have been exported, but in moderate quantities. Coffee has likewise been cultivated with good success—but nature has done too much in Corrientes.

The river Uruguay separates on their eastern sides both the preceding provinces from Banda Oriental.

Paraguay is the next province to Corrientes, with the Parana intervening. Here again, the courses of the rivers give compactness and a defined natural outline to a political section. The Parana, after having been swelled by innumerable streams from the mountains of Brazil, crosses the southern tropic, and flows southward with a very slight inclination to the west, to below S. lat. 27°, when abruptly turning to west, one hundred and fifty miles, unites with the Paraguay, and encloses the province of the latter name on two sides; which province is again washed on the west by the great river from which its name is derived. On the north Paraguay bounds on the Brazilian province of Matto Grosso. The whole forming an oblong 280 by 200 miles; area 56,000. Such is Paraguay on our maps, but the following extract shows how imperfectly the physical or political features of this remote region is known even at Buenos Ayres.

"It is undoubtedly one of the provinces which has always been held in most estimation, on account of the abundance, variety, and value of its productions. For the last 15 years, however, (from 1825) which goes back to the time when, with Buenos Ayres, it separated itself from the Spanish domination, it occupies an obscure place in the politics of that country, and maintains no social or mercantile relation with any other part of the world; for which state of seclusion it is favoured by its detached local situation. Without knowing whether this circumstance ought to be attributed to the rustic character of the only person who has governed Paraguay, during the greatest part of that time, or to the constitutional apathy and ignorance of the persons governed, the fact is, that notwithstanding it followed the sentiment of the whole territory, as regards its separation from Spain, that province has not only taken no part in the war of independence, but also, since that moment, has cut off all communication with the contiguous and united provinces, and thus continued to the present time to prevent the exportation of its interesting productions, and to prohibit the return of all foreigners or natives, with very few exceptions, who came for the purpose of introducing ultramarine merchandise into Paraguay. *Hence, nothing is known of that province which is not of an old date; and that information, of course, is liable to all the inaccuracies with which such communications were constantly divulged in those times.*"*

The author of the preceding goes on to state what important facts are known of Paraguay. It abounds in mountain forests of the finest ship timber, and though so far inland, the construction of vessels has always been one of its principal branches of commerce. Most of the small vessels employed in the trade of all the internal rivers, have been constructed there. In Paraguay some ships have been built, which have been navigated to Buenos Ayres, a distance of 1200 miles. In the year 1824, one of those ships sailed to Lima, after having made several voyages to Europe.

This province seems to produce in highest perfection that remarkable herb, (yerba mate, or the *chenopodium ambrosioides* of Linnæus) the tea of South America. It has been noted for the excellence of its tobacco, cotton, and many other vegetables. It has also gained a shameful notoriety by the forcible detention of M. Bompland, who was so long and usefully the companion of Baron Humboldt, and who was sent as a naturalist by the government of Buenos Ayres, to explore those recesses situated between the Missiones of Corrientes and Paraguay.

The three provinces we have surveyed constitute the territory of the republic of the United Provinces of la Plata to the east, or along the right bank of Parana; extending through upwards of ten degrees of latitude, and comprising an aggregate of 135,000 square miles, most advantageously situated for every pursuit necessary to human prosperity, happiness, and improvement. In general character, the face of the country to the east and west of the Parana and Paraguay differs essentially. The dense forests of Entre Rios, Corrientes, and Paraguay, are followed, advancing towards the Andes, by the Llanos de Manso, and other interminable grassy plains, which occupy the far greater part of the regions from the Parana and Paraguay to the mountains of Chile.

Santa Fe gives name to a province north-west from that of Buenos Ayres. This city is the first on the road from Buenos Ayres to Paraguay, at a distance of 300 miles above the capital, and at S. lat. 31° 32′. It stands on the Salado, at its entrance into the Parana. The province of Sta. Fe is bounded by Buenos Ayres south, Cordova north, and the barbarian frontiers south-west. The population is very scanty, and the number of its inhabitants unknown; supposed to be from 15,000 to 20,000. With all the advantages of position and soil, agriculture is neglected. The inhabitants are devoted to rearing horses and vicunnas. Its productions are conveyed to Buenos Ayres by land, as well as by water.

Cordova is the capital of the province of that name, and the first city to which the traveller comes after leaving Buenos Ayres, in following the western road, which is commonly called the road of Peru. It was founded in July 1573, and is situated at S. lat. 31° 15′, about 400 miles N. W. from Buenos Ayres. Its situation is picturesque, amid mountains. The city alone contains a population of from 12 to 16.000 souls, and that of the whole province may amount to from 70 to 80,000. The territory of Cordova remains but vaguely defined, but is usually considered about 330 miles square; which would give nearly one hundred and nine thousand square miles; but such estimates without adequate data are of little value. Many circumstances of interest respecting this province are, however, known. The city contains a university tolerably well endowed. In the territory there are many towns and places of whites and Indians; such as Concepcion, Carlota, Tutumba, San Xavier, Rio Seco, Frayle Muesto, Soto, Pichano, Quilino, Yschitin, La Toma, San Marcos, Cruz Alta, and several others, with a very scanty population in each. The greater part of the inhabitants being spread about the country, on the *Haciendas* or *Estanias*, establishments for grazing.

Agriculture is neglected, though wheat and other grains succeed well; but the people are pastoral, mild, and happy. If the pursuits of the people of Cordova did not assimilate to those of the banks of the Parana, we might ascribe the pastoral character of the former to the nature of their rivers: no navigable stream flows from Cordova. But on the Parana, Paraguay, and Uruguay, and even at Buenos Ayres, the people are pastoral. This general similarity in the habits of society in places so very remote, and in places so physically distinct, must have for causes something which writers have not sufficiently explained. The effects every traveller must observe. Most of the rivers of Cordova are lost in the intermediate plains before reaching the Parana. One is an exception, which reaches the Parana at Rosario, but it is unnavigable. In 1804, and 1810, attempts were made to remove the obstructions to the navigation of this river, but proved abortive. In fact, to complete such works demands a more dense and enterprising population than exists on Cordova.

St. Louis, or San Luis de la Puntz, still more remote from Buenos Ayres than is Cordova, and still more deprived also of the benefits of navigable rivers. This city lies on the road to Mendoza, at S. lat. 33° 22′ about 500 miles a little north of west from Buenos Ayres, and 300 miles east from Santiago de Chile. Though founded as early as 1565, it yet contains only 1500 inhabitants. The province is about 300 miles by 180, and contains on an area of 54,000 square miles a population of 25,000 souls. The temperature of the air is good; and yet, the lack of population in the towns, and culture in the country, greatly diminish its importance. It is well calculated for breeding cattle, and the rearing of horses and vicunnas,

* Historical, Political, and Statistical Account of the United Provinces of Rio de la Plata, page 251. London, 1825.

the chief employment of the people. Occupying a point on the great road from Buenos Ayres to Mendoza, Santiago de Chile, and other places, San Louis, may with a more numerous and more industrious popula'ion, become a city of great importance.

San Juan, a city at S. lat. 29° 20′, 60 miles north from the termination of the jurisdiction of Mendoza, remained until recently almost unknown, though founded 270 years, and contains a population of upwards of 20,000 souls; and 35,000, if the adjacent villages of Las Lagunas, Pueble Viejo, Jacha, Valle Fertil, &c. are included. It stands 700 miles N. W. from Buenos Ayres. The province is about 300 miles square, terminating like Mendoza, on the summit of the Andes.

In all the provinces of the republic of Rio de la Plata, hitherto noticed, we have found pastoral life prevailing, but approaching San Juan and Mendoza, we perceive a favourable change. The former city, is now considered as that which most closely follows Buenos Ayres in the march of social reform. In particular, the people of San Juan have made astonishing progress in ecclesiastical reform. They have incorporated the regular with the secular clergy, and suppressed the convents. In regard to agriculture, this city and territory competes with Mendoza. The inhabitants cultivate the vine to great extent, and export wines and brandies to Potosi, Buenos Ayres, Santa Fe and other places. The fertility of the soil is so great that wheat produces a hundred fold. The olive tree is also much cultivated, and the fruit and oil are great objects of commerce. In the northern part of the province gold mines abound; and from one, that of Tacha, an average of 80,000 dollars is drawn annually.

Mendoza, a city containing a population of 15,000 souls, was founded on the eastern side of the Andes in 1560. It stands at S. lat. 35° 50′, on the direct road from Buenos Ayres to Santiago de Chile, 650 miles westward from the former, and 150 eastward from the latter city. The ground on which Mendoza stands is elevated 4656 feet above the ocean. The provincial jurisdiction of Mendoza is bounded west by the Andes, south by the river Diamante; on the north and east it touches San Juan and San Luis, and on the south-east borders on the savage or barbarian frontier. The whole province is about 400 miles from north to south, with a breadth of 300 east and west. This would give an aggregate of 120,000 square miles, but the far greater part is merely nominally connected with the capital, and much spread into the pampas, and is uninhabitable.

The really cultivated section adjacent to Mendoza, is, however, amongst the best improved parts of Spanish America. Beside the capital there are several towns of considerable note, such as San Carlos, towards the south in the valley of Uco, Coriconto, towards the east, and another, Los Barriales, in the same direction. Towards the north, at the very extremity of the jurisdiction, lies a town, the name of which sufficiently expresses its favourable locality—*Las Grandes Lagunas de Guanacache*.* Towards the N. E. six miles from Mendoza, stands San Vincente, a town of considerable importance. Entire population 35,000 souls.

The inhabitants of the city and province of Mendoza, are amongst the most enlightened of the republic, as is proved by the facility with which religious and political fanaticism have yielded to more liberal opinion. The character of the inhabitants of both sexes is amiable and hospitable. This city was rendered remarkable in the annals of the revolutionary war, because in it was organized the army which carried independence to the republic of Chile, and which also opened the road to that of Peru. The province is the most agricultural of the republic to which it belongs, and its people most devoted to labour. Their chief employment consists in the cultivation of vines, clover, and other productions usually met with in a fertile soil abundantly irrigated. They also carry on an extensive traffic in wine, brandy, and dry fruits, with the neighbouring provinces, particularly Buenos Ayres, Santa Fe, and Paraguay, managing even to export dry fruits as far as Brazil. The country produces Indian corn and wheat adequate to the internal consumption. The people of Mendoza are also actively and very extensively engaged in the transport trade, from Buenos Ayres to Chile.

Rioja, a small city situated on one of the highest branches of the river of Mendoza, at S. lat. 28° 25′, and 870 miles to the north-westward of Buenos Ayres, and 400 miles to the northward of Mendoza, though containing only 2 or 3000 inhabitants, is the capital of a province of considerable extent, and with a population of 20,000 souls. The province has the Andes of Chile west, the province of Tucuman north and east, and San Juan south. It is about 400 miles in length from north to south, with a mean breadth of 300, or with an area of 120,000 square miles; but of this great superficies little is cultivated or inhabited by a civilized people. The deficiency of population is not owing to a defect of soil or climate, since both are admirable. Wheat and the vine are cultivated, but pastoral pursuits and mining are preferred to agriculture. Famatina, one of the most productive mines of America, lies in the Andes, about 100 miles west from the city of Rioja. This province is subdivided into four departments, Los Llanos, (*the Plains*) Aranco, Famatina, and Guandacol.

Santiago del Estero, (*Santiago of the lake*) stands on the right bank of the river Dulce, 600 miles N. N. W. from Buenos Ayres, and almost exactly equidistant, 350 miles, and directly between Rioja and Corrientes on the Parana. It may be noted as a very remarkable and important feature in the physical features of that section of South America comprising the provinces of Cordova, Mendoza, San Juan, San Luis, Rioja, and Santiago del Estero, though embracing a surface upwards of 500 miles square, or 250,000 square miles, have no navigable outlet. The most remote northern sources of the Colorado, which flowing S. E. enters the Atlantic Ocean at S. lat. 40°, are found above Rioja at S. lat. 27°; but though flowing through the provinces upwards of 600 miles, it affords no navigable facilities worthy of notice. Leaving the civilized settlements, this stream crosses the pampas and reaches its point of discharge far south from any white establishment. From the Colorado, in the southern part of Mendoza, to the river of Santiago or Dulce inclusive, in a distance from S. W. to N. E. of 500 miles, only one river, that of Cordova, reaches any outlet. The river which passes Santiago del Estero, called

* Guana, is a species of American palm tree, and this town must have been named from the Lagunes or lakes where that vegetable abounds. Guanacache, on Tanner's map, is at S. lat 31° 10′, 200 miles N. N. E. from Mendoza.

the Dulce, rises in the mountains of Tucuman, flows south-eastward about five hundred miles, and is lost in an interior lake; and such is also the case with numerous other rivers which issue from the Andes and pursue their courses towards, but never reach the Parana.

The city of Santiago del Estero was founded about 1551, at S. lat. 27° 28′. The city is thinly peopled, but the number of inhabitants under its jurisdiction may be computed at 50,000, whose principal occupation is agriculture. It is a country well adapted to grain, of which sufficient is produced for home consumption. The provincial extent of Santiago is too undefined to admit an estimate of its superficies.

Tucuman, a city containing 10 or 12,000 souls, follows advancing northward, Santiago del Estero, at the distance of one hundred miles. The former is at S. lat. 27°, about 650 miles north-westward from Buenos Ayres, on the road from that city to Upper Peru. The population of Tucuman does not exceed 12,000 souls, but the whole province, it is probable, contains an aggregate of 40,000. The territorial extent is small, being only about 150 miles from east to west, by 180 miles from north to south; area 27,000 square miles. It is a country well adapted to agriculture and grazing, and both are followed by the inhabitants; wheat, rice, Indian corn, and tobacco are produced. Esculent roots abound, particularly potatoes of extraordinary size and flavour. Cotton and woollen stuffs are made here of cheap but good quality, for home use and exportation. Though bordering on the Llanos or plains, the higher part of Tucuman abound in forests of very large timber. The city itself is environed in one of those woods, in which upwards of fifty species of trees have been enumerated.

In the war of independence Tucuman acted a very distinguished part. In 1812, a splendid victory over the royalists was gained in its vicinity, and in this city, in 1816, was drawn up by the general Congress the Declaration of Independence, as well of Spain, as of every other foreign power, which had only been the case, *de facto*, since the 25th of May, 1810. The inhabitants, are affable, amiable, hospitable, and honourable in their dealings, as well as industrious in their habits.

Catamarca, the territory of which lies east from that of Tucuman, and south-east from Salta, was founded about 1680, and contains a population of 4500 souls. The whole province is inhabited by 35,000, including with those of the city, the towns of Piedra Blanca, Sierra del Alto, Sierra de Ancasti, Tinogasta, Santa Maria, and Belen. The territory is not well defined, but in the 26th degree of south latitude, the climate is mild and the soil productive. Though grazing has been more attended to than agriculture, grain and cotton are made for domestic use and for exportation. Reaching the Bermejo river, the unnavigable character of the streams begins to change for the better. The Bermejo, by numerous sources, flows from the Andes of Salta and Jujuy, and crossing these provinces, unite above Catamarca, and turning to south-east, reaches the Paraguay after a course of 700 miles. With all this great length of course, this fine stream cannot be navigated to its mouth. We have already noticed abortive projects to remove the obstructions in its bed. In the actual state of things, the produce of Catamarca, like that of all the neighbouring provinces, must find a market by land carriage.

Salta, situated at S. lat. 24° 50′, on the road from Buenos Ayres to Upper Peru, 950 miles north-north-westward of the former. This city was founded in April, 1582, and has for its territorial boundaries, those of Jujuy, Tucuman, Attacama, and the great Chaco of Potosi. The population of the city and suburbs amount to about 10,000, but the whole country 40,000, including the inhabitants of Caldera, Rosario de la Frontera, Rosario de Serrillos, Chicoana, Auta, Sumalas, Goachipas, Serrillos, Campo-Santa, Zoras, Corras, Valle de San Carlos, Valle de Calley, Rio del Valle, Balvuena, Mira-Flores, and Macapillo. The province of Salta, though under the southern tropic, or but little advanced into the southern temperate zone, enjoys a mild climate. Many branches of the Andes extend themselves into its recesses, and approach the Bermejo river. The country abounds in forest timber, and though unprovided with navigable channels, no country can be more abundantly supplied with pure and wholesome water. The mines of gold, silver, and copper, are much celebrated, and the province produces also iron, sulphur, and alum. The principal article of exportation is mules, which to the amount of from 60 to 80,000 head have been sent in one year to Peru. Salta possesses the first materials of the three kingdoms, animal, vegetable, and mineral, and it is already peopled by inhabitants worthy of their advantages. Measures are there adopting to render the Bermejo navigable; and a company is forming for that purpose in Buenos Ayres.

Jujuy, a small city about 100 miles north from Salta, stands on a river of the same name, a branch of the Bermejo, at S. lat. 23° 50′, and 13° 05′ long. E. from Washington City. It was founded in 1591; its territorial jurisdiction about 120 miles from east to west, and 210 from north to south; bordering to the north-west on Potosi, to the south on Salta, and to the north and east on Oran and Great Chaco; population of the province 30,000 souls. Wheat, barley, maize, and different kinds of pulse, potatoes, sugar, honey, and brandy are exported, but the principal employment of the people is in breeding sheep, vicunnas, horses, and mules. The mules are here, as they are to an immense extent in Spanish America, the means of transportation, and are themselves again the most valuable article of commerce. Jujuy would be most signally benefited by the opening of the Bermejo to navigation.

Upper Peru includes all that territory belonging to the Republic of Rio de la Plata, which begins where the jurisdiction of Jujuy finishes, and ends at the river Desaguadero; on the opposite bank of which begins the Republic of Peru. Limiting Upper Peru, however, by the Desaguadero, a small river, flowing north-west into the lake Titicaca, or Chicuita, must mean its termination in that direction, since to the northward this country stretches down the higher branches of the Madeira and Ucayale rivers, 6 degrees of latitude beyond the mouth of the Desaguadero, and reaches S. lat. 12°.

The author we have followed in our view of the provinces of Rio de la Plata, under the head of Upper Peru, observes that, "On account of the occupation of this province by the Spaniards, it has been impossible to obtain any statistical account posterior to the revolution. All that is known for certainty is prior to that event; and with the idea of giving preference to what has been published within the country itself, the following accounts are extracted from a book printed in Buenos Ayres, in the year 1803, under the title of *A Guide to* FOREIGNERS, *in the Viceroyalty of Buenos Ayres.* This authority informs us, that under the Spanish government, Upper Peru was subdivided into the four provinces of Potosi, Cochabamba, Charcas, and La Paz.

POTOSI, the city, which contains a population of about 20,000 souls, was founded in 1545. It stands at S. lat. 19° 28′, on one of the higher branches of the Pilcomayo river, upwards of 1200 miles, following the nearest road, N. N. W. from Buenos Ayres. The province, as near as we are able to define its boundaries, extends from the river Jujuy in S. lat. 24°, to the Desaguadero, S. lat. 18° 50′; and from the river Tarija to the Andes east and west. Length 350, mean breadth 170, area about 60,000 square miles. It is drained by the Vermejo and Pilcomayo rivers. The name and celebrity of this province and city were derived from the great mine mountain in the vicinity of the city. The mine was opened on the 21st of April, 1545, and the city increased so very rapidly, that in 1611 it contained 160,000 persons, but subsequently declined to about 30,000. It is supposed, on good authority, that in 255 years, from 1545 to 1800, that the mines of Potosi yielded upwards of *one thousand six hundred and forty-seven millions, nine hundred thousand dollars*, or above 6,462,000 dollars annually. One consequence of this abundant and continued production of the precious metals has been, that Potosi as a country remains poor, thinly peopled, and uncultivated.

CHARCAS follows Potosi, from which it is separated by the river Paspaya, a confluent of the Pilcomayo, and extends north to the river Guapey, a branch of the Madeira, and which separates it from Cochabamba. This province, known by the various names Charcas, Chuquisica, and La Plata, lies between 18½° and 21° S. lat.; is about 400 miles long from west to east, with a mean width of 100 miles, or 40,000 square miles. This province occupies a table land from which the waters of the Madeira flow northward towards the Amazon, and those of the Pilcomayo descend south-eastward towards the Paraguay. The climate has been the admiration of all travellers, and to this many incidental advantages recommend it; for instance, its university, the superior education of its inhabitants, with their polished manners, and the rich productions of its fields and pastures.

La Plata, or Chuquisaca, the capital, stands on a branch of the Pilcomayo, at S. lat. 19° 27′, about 65 miles N. E. from Potosi. It was founded by Pedro Azures, and made a bishopric in 1551, and in 1608 raised to a metropolitan city. Before the late revolution, it was the seat of a royal audience, and contained 15,000 inhabitants; whole province 30,000.

COCHABAMBA is the first province which we have reached amongst those appertaining to Buenos Ayres, which lies entirely in the basin of the Amazon. This province was founded in 1572, and from the following account, taken from a manuscript document preserved in the public library of Buenos Ayres, containing the observations of Don Thadeus Haenke, it is very erroneously laid down in our maps.

"The territory of the province of Cochabamba forms a long and narrow strip of land, which, with but little variation, runs from west to east. Its length is about 130 geographical leagues, (20 to a degree, we may presume, or about 3⅓ English miles) more or less, supposing it a straight line; and its diameter, under the same supposition of a straight line, does not exceed the space of 20 or 30 leagues. Its direction is almost from north to south." From these observations, the province of Cochabamba contains an area of about 43,000 square miles, and although in its territory gold and silver mines are not found as they are in most parts of Upper Peru, it is a country of the first importance. Its soil is proverbially fertile, and the elevation and variety of its surface give it almost every variety of climate. The population amounts to upwards of 100,000 souls, and it is one of the best peopled provinces of the whole republic to which it belongs. The pursuits of the people may be seen from their productions for export, which are indigo, cacao, cochineal, wools of the vicunna and of alpaca (*cavia paca* of Linnæus) grains, &c.

LA PAZ terminates the republic of the United Provinces of Rio de la Plata. It was founded in 1548, at S. lat. 17° 20′, in a ravine on one of the extreme higher sources of the Ucayale, and by any road upwards of 1500 miles N. N. W. from Buenos Ayres, and 700 S. S. E. from Lima. The provincial territory of La Paz lies in one of the great vallies of the Andes, and is drained by the Beni, a confluent of the Ucayale. It extends from S. lat. 13° to 18½°, leaving the remarkable lake Chicuito or Titicaca to the westward. On the high parts the climate is cold and variable. Some of the mountains rise above the region of perpetual snow; but the vallies are warm and very productive.

We close our account of the United Provinces of Rio de la Plata by the subjoined tabular summary of the extent of the provinces and their population in 1825. The reader must be aware, nevertheless, that the estimates are too much founded on defective data to deserve entire confidence, but we trust with all its imperfections it may serve to give a general view of this interesting country.

Provinces.	Sq. miles.	Population.
Buenos Ayres,	20,000	163,316
Entre Rios,	39,200	30,000
Corrientes,	40,000	50,000
Paraguay,	56,000	30,000?
Santa Fé,	30,000	20,000
Cordova,	109,000	80,000
San Luis,	54,000	25,000
San Juan,	90,000	35,000
Mendoza,	120,000	35,000
Rioja,	120,000	20,000
Santiago del Estero,	250,000	50,000
Tucuman,	27,000	40,000
Catamarca,	25,000	35,000
Salta,	25,000	40,000
Jujuy,	25,200	30,000
Potosi,	60,000	60,000
Charcas,	40,000	30,000
Cochabamba,	43,000	100,000
La Paz,	40,000	35,000
	1,213,000	908,316

The physical extent north and south of the Republic of the United Provinces of Rio de la Plata, may in general terms be considered as reaching from S. lat. 13° to 40°, or through 27 degrees of latitude: in longitude from the western border of La Paz to the eastern angle of Corrientes, from 7° to 21° E. from Washington City, or through 14 degrees of longitude. Having the Andes west, Lower Peru north, the Brazillian provinces north-cast and east, the Atlantic Ocean south-east, and the wide and almost unexplored regions of Patagonia south.

Rigidly measured, there would be a larger superficies enclosed within the outlines, than is shown in the preceding table, but as a habitable section of the earth, the table yields a more conclusive result than would an aggregate including extensive tracts upon which a dense population could not subsist. In its actual state, if we suppose the inhabitants to have augmented to a million, there are only 82 on 100 square miles. In fact, the great error committed by the Spaniards in colonizing America, was that of spreading their physical force over too wide a surface; therefore, the actual settlements, after a lapse of three centuries, are detached from each other, and individually weak, if we except Mexico and a part of Colombia and of Peru.

On one million of square miles of the Republic of Rio de la Plata, 200 persons to the square mile could be amply supported, or that country might sustain a population of two hundred millions, which would be nearly equal to that of Europe at the present time.

To the south from the basin of the Rio de la Plata, again spreads a vast region in the temperate latitudes, which in the course of events must receive a civilized population from the contiguous provinces; it is therefore no risk to say that there is a continuous surface of one million and a half of square miles on which the population of the republic of the Plate may expand, and it is as safe to say, that the population of these regions will double in each 30 years.

In treating of the three great divisions of Colombia, Brazil, and the United Provinces of the Rio de la Plata, though the data was far from being in either case ample or perfect, yet the elements for the residue of South America, are still more deficient; but we hope to make the view correct, as far as our means will admit.

In regard to geographical connexion, the republic of Chili, or more correctly Chile, follows that of the Rio de la Plata, having the great system of the Andes intervening.

Chile extends along the Pacific Ocean from S. lat. 24° 20′ to S. lat. 44° or through 1180 minutes of latitude, equal to a fraction above 1356 miles; but the breadth inland from the Andes does not exceed, if it amounts to 100 miles: the area is about 135,000 square miles. This extent is, however, very much restricted in regard to civilized settlement. The river Biobia at S. lat 36° 50′, separates the white from the Araucanian territory, consequently the population of Chile, exclusive of independent Indians, exists on the $12\frac{1}{2}$ degrees of latitude north from the Biobia river, or on 86,250 square miles. Beyond the Indian country, the republic holds the archipelago of Chiloe, with about 26,000 inhabitants. The main island is about 140 miles long from north to south, with a mean breadth of perhaps 30, and 4200 square miles. The whole surface of Chile, upon which resides a civilized people, a little exceeds ninety thousand square miles. By a census taken about 1812 the provinces of northern Chile contained a white population of 1,200,000, and the Chile islands 26,000; the whole 1,226,000; yielding a distributive population of $13\frac{6}{10}$ths to the square mile. The provinces are, advancing from north to south, Copiapo, Huasco, Coquimbo, Cuscos, Petorca, Aconcagua, Quillota, Santa Rosa, Mellipilla, Mapocho, Rancagua, Colchagua, Curico, Maule, Canquenes, Isla de Maule, Chilan, Puchacay, Chillan, Rere, Conception, and Isla de Laxa.

Santiago, the capital of Chile, at S. lat. 33° 20′, was founded in 1541, by Pedro de Valdivia, under the provincial name of Nueva Estramadura. It stands about 90 miles from the ocean, and 21 from the foot of the Andes, about 100 miles north-westward from Mendoza, and nearly an equal distance S. E. by E. from the port of Valparaiso. It is a fine city, containing a population of 50,000 souls; is well built, paved, and admirably supplied with pure fountain water. Standing on the thoroughfare from Buenos Ayres to Valparaiso, it is an entrepot for an immense merchandize. The inhabitants have been noted for their lively and hospitable character. The climate of Santiago is much influenced by its height, which is $2347\frac{3}{4}$ feet above the level of the Pacific Ocean.

Valparaiso, the port of St. Jago, is built on a rocky peninsula, forming a crescent, within which is the harbour. Population 6500. S. lat. 33° 2′. This is the most commercial port, perhaps in America on the Pacific Ocean.

Conception is the second largest city, and the outpost of Chile towards Araucania. It stands at S. lat. 36° 40′, on a bay made by the Biobia river, and on the north side of the river, 3 miles above Talcahuana the port; 350 miles S. S. W. from St. Jago. The harbour of Biobia is safe, and admits the largest vessels.

The other important seaports of Chile, are Copiapo, S. lat. 27° 15′, Coquimbo, or La Serano 29° 54′ S., and Valdivia. The latter is, however, in Araucania, at 39° 50′ S., and though one of the most capacious and safe harbours of America, is commercially of no moment.

In regard to climate, that of Chile is peculiar in America. South from the Maule, or about S. lat. 35°, the seasons are variable. Proceeding north along the Pacific coast, from the Maule, rains become more and more rare, until in the provinces of Coquimbo, Huasco, and Copiapo, it ceases entirely. The air is from November to May cloudless: dews are light, and throughout the year an unequalled serenity prevails. The temperature fluctuates between 70° & 80° of Fahrenheit, and very seldom rises to 85°. Thunder storms are extremely rare in this region of atmospheric tranquillity.

Mines of gold, siver, copper, iron, lead and tin, abound in the northern provinces of Chile. The precious metals are in particular produced in great plenty. Wheat and hemp are named amongst the exports, but agriculture is not in an advanced state.

The revolutionary movements in other Spanish American colonies, extended to Chile, in 1809, and from that period until 1818, the country alternately submitted to the Spanish royalists, or declared themselves independent. In 1817, general San Martin led an army from Buenos Ayres, by Mendoza, into Chile, and after many previous successes, secured Chilean independence by the splendid victory of Maypo, April 5th, 1818. A constitution of government was subsequently formed, and Chile ranks amongst the nations of the earth.

Our survey of Colombia, Brazil, the United Provinces of la Plata, and Chile, has brought us round to the highly interesting country of Peru.

Peru, if taken in the utmost extent, includes, as we have seen, the four north-western provinces of the republic of Rio de la Plata, but what has been called Upper Peru will, it is probable, be soon antiquated, and leave the term to designate that great section of South

America, having the Pacific Ocean west and south-west, Colombia north, and Brazil east, and the United Provinces of Rio de la Plata and Chili south-east. Extending along the Pacific Ocean from the river of Tumbez, S. lat. 3° 47′, to the Desert of Atacama, 21° 30′ S. and in long. from 12° E. to 4° W. from Washington city. Within these limits is included an aggregate area of something above five hundred and thirty thousand square miles; physically divided into two unequal inclined planes. The western or Pacific plain, narrow and steep, is in no place 80 miles wide, in some not 30, and does not average above 50 if so much, but stretches the whole oceanic border of Peru, 1500 miles. The Andes of Peru have never, it is probable, been well defined on any map. Their range is, however, known with more precision than the collateral ridges or chains. The whole system of the Andes follows the general course of the opposing coast, and consequently, between S. lat. 5° and 16°, the Andes extend from north-west to south-east.

The middle branches of the Amazon, rising from 3° to 5° S., flow eastward from Loxa and Jaen of Colombia, crossing the mountain vallies nearly at right angles. On the contrary, the southern confluents of the Amazon rising in the mountain vallies from 10° to 18° S., pursue the course of those vallies to the northwest, as is the case with the Ucayale and its numerous confluents; the Gualaga and its branches, and also the Lauricocha. Thus the higher tributaries of the Maranon or Amazon drain an inclined plane, having its descent along, and not from the system of the Andes. It is from this singular physical structure, that the relative terms have arisen of Upper and Lower Peru. The two extremes of the eastern Peruvian plain, the province of Cuzco, and the eastern part of Truxillo, occupy the higher and lower part of this slope, though both are at about an equal distance from the Pacific Ocean.

Under the head of Colombia, we have taken some pains to describe the very elevated vallies of the Andes. We have found those high arable plains from one thousand to ten thousand feet, in the provinces of Popayan, Pasto, Ymbabura, Pichincha, Chimborazo, Cuenca, Loxa, and Jaen; and we find neither their extent nor height diminished in Truxillo, Tarma, Guancavelica, Guamango, and Cuzco in Peru. In Peru, as in the mountain regions of Colombia, all the climates of the earth approximate, but the excess of heat is in no part of either as high as the latitude would seem to indicate. By the meteorological tables of Lima, published by Dr. Unanue, in his admirable work on the climate of that capital, which were made out for the years 1799 and 1800, it is found that the greatest degree of heat in Lima is $20\frac{2}{3}$° of Reaumer, or 77° of Fahrenheit, and the lowest 13° of Reaumer, or 61° of Fahrenheit. On the mountain table lands there is scarce any change of temperature. The woods and fields are always verdant, and the grains and fruits of Europe flourish amid the vegetation of the torrid zone—Fahrenheit's thermometer standing at about 65° or 66°, a little below the mean of Lima. Amid this perennial summer on the east and table lands, eternal snow lies on the higher Andes, and the human frame may be reposed on a couch surrounded with an unvarying, mild, and salubrious air, with the eye fixed on the region of never relaxing frost.

The narrow slope along the Pacific has been called the country of *valles;* here rain, thunder, and lightning are rare, indeed scarcely known; but the want of moisture gives barrenness to the soil, except where proximity to rivers permits artificial irrigation. Wine, oil, and sugar are produced on the valles; the high plains abound in grain, Peruvian bark, and cacao. The mountains are productive of mineral wealth. In 1791 the mines of gold, silver, quicksilver, copper, and lead, yielded under a very defective management, an annual amount of 4,500,000 dollars, of which seven-eighths was silver.

The most important difference, however, between the *valles* and high plains regards health. On the latter, intermittent, malignant, and catarrhal fevers are prevalent; on the former salubrity prevails, with as little interruption as in any part of the earth.

Under the Spanish government, Peru, like Mexico, was subdivided into intendancies; and since the emancipation of the Spanish colonies few provincial changes have been made, it will suffice, for a general view, to give the political sections as they stood in 1795. At the latter epoch Peru was divided, advancing from north to south, into the intendancies or provinces of Truxillo, Tarma, Lima, Guancavelica, Guamanga, Cuzco, and Arequipa.

Truxillo is bounded north by Colombia, west and north-west by the Pacific Ocean, south by Tarma, and east by the uninhabited regions between the Gualaga and Ucayale rivers. In latitude it stretches from 3° 25′ to 8° 50′ S.; and in long. from 4° 05′ W. to 2° E. from the meridian of Washington City. Length along the Pacific Ocean 400 miles, mean width about 180, area 72,000 square miles. The north-western part of this province, sometimes distinctively called Piura, is the most western part of South America, a part of a burning and barren slope, but thinly peopled; the eastern section, between the Tunguragua and Gualaga rivers, is also in great part uninhabited, leaving for the civilized and cultivated tracts in Truxillo, the mountain valley of the Andes, watered by the Lauricocha river. In 1795 the whole province contained an aggregate population of 230,176, which was composed of whites 19,098, Indians 115,647, Mestizoes 76,949, Mulattoes 13,757, and African slaves 4725.

Truxillo, a city and seaport of the province of the same name, stands on the Pacific, S lat. 8° 01′. It was founded in 1535, by Francis Pizarro: present population uncertain. Caxamarca, on the Tunguragua, is about 100 miles inland, and north east by east from Truxillo; S. lat. 7° 40′ This is no doubt one of the most ancient cities of America. It was one of the great capitals of Peru under the Incas, and the ruins of palaces and temples yet exist. Population 12,000.

Tarma, between S. lat. 8° 15′ and 12°, follows Truxillo, having the Pacific Ocean south-west, Lima south, the uninhabited regions towards the Ucayale east, and Truxillo north. The outlines of Tarma are very irregular, but the area may be estimated at about 26,000 square miles; on which, in 1795, existed a population 200,928, of whom were whites 15,939, Indians 105,187, Mestizoes 78,682, Mulattoes 884, and African slaves 236.

The south-east part of Tarma must be amongst the elevated table lands of South America. The rivers Lauricocha and Gualaga there interlock sources with the Apurimac; the two former flowing to the north-west, and the latter to the south-eastward. The Indian town of Tarma, with about 6000 inhabitants, stands on this elevated plateau, at S. lat. 11° 20′, and about 85 miles north-east by east from Lima.

Lima, containing the capital of Peru, stretches from S. lat. 10° 18′ to 15° 30′, bounded by the Pacific Ocean on the south-west, by Tarma north and north-east, Guancavelica east, and Guamanga and Arequipa south-east. It is about 400 miles in length along the Pacific Ocean, with a mean breadth of 80 miles inland; area 32,000 square miles. Being comprised in great part of the valles of the Pacific coast, though containing the capital, Lima is not so well peopled as are the provinces spreading along the table land of the Andes. In 1795, there were in Lima 22,370 whites, 63,180 Indians, 13,747 Mestizoes, 17,864 Mulattoes, and 29,763 slaves, forming an aggregate of 146,924.

Lima, the capital, stands on the high plain of Rimac, from which by a curious corruption the permanent name of the city was derived. Called in the first instance Ciudad de los Reyes, Lima was founded, January 15th, 1535, by Francis Pizarro, and with many other of his works, evinces the keen sagacity of that ferocious conqueror. The city is six miles from Callao its port, and though the intermediate space is level, it is nevertheless an inclined plane, rising from the ocean upwards of five hundred feet. This gradual but comparatively great elevation gives to Lima its admired command of view, and also enables the inhabitants to drain their streets by constant running water, from the small river, the mouth of which forms the harbour of Callao. The houses, public and private, are many of them as splendid and solid as the frequent occurrence of earthquakes will admit. The churches are numerous, but the most important edifice is that of the University, founded in 1576. The number of inhabitants has been stated variously, but generally supposed about 54,000, of whom one third are whites. Having been for nearly three centuries the centre of commerce and political power, Lima is a city of much wealth and luxury, and is beyond any dispute the finest city of America on the Pacific coast.

Callao, though six miles from Lima, cannot be regarded as more than a suburb, though containing a population of 6000 souls. The inhabitants of both cities have been admired for urbanity of manners, and a lively active genius. The adjacent country is in a peculiar manner delightful, but the pleasure of viewing this beautiful picture is damped by the reflection that it is the outside of a region liable to frequent and most destructive earthquakes. In 1786, Lima was shaken and upwards of a thousand of its inhabitants destroyed; and at the same moment Callao was ingulfed, and only two hundred out of four thousand lives were saved. This was only one of many similar visitations recorded in the history of the two cities.

Guancavelica, containing an area of about 10,000 square miles, and lying east from Lima, with Tarma north and Guamanga south-east, is a mountainous region, which has been rendered remarkable from one of the most extensive mines of quicksilver yet discovered in America. Though lying between S. lat. 11° 40′ and 14° 30′, it is a cold, and in many places a frozen region. The city of Guancavelica from which the province is named, is perhaps the most elevated town ever inhabited by man. It is upwards of 12,300 feet above the ocean level, and the quicksilver mines of Santa Barbara, in the vicinity, are 2200 feet still higher. The population of this aerial city, though greatly diminished in number, still exceeds five thousand souls. The valley and plains composing the province of Guancavelica, are drained by the Jauja, Bangara, and other rivers forming the higher north-western branches of the Apurimac. The whole province is about 200 miles by 40 miles; area 8000 square miles, with a collective population of 30,917, of whom only 2341 were whites.

Guamanga has Guancavelica and the southern part of Lima west, Arequipa south, Cuzco east, and the plains of the Apurimac north and north-east. The central and civilized settlements of this province are contiguous to Guamanga the capital. The whole province contained in 1795, 111,256 inhabitants, of whom only 5378 were whites, and the residue 75,284 Indians, 29,621 Mestizoes, 943 Mulattoes, and 30 slaves. This province is about 300 miles by 60 miles; area 18,000 square miles.

The name of the principal river flowing from Guamanga explains the nature of the country; it is called the Pampas, or river of the plains. The capital containing 26,000 souls, occupies an unhealthy situation on a confluent of the Bangara river, at S. lat. 13° 8′, and 250 miles S. E. by E. from Lima.

Cuzco, a city containing about 40,000 inhabitants, the ancient seat of the Incas of Peru, is situated at the foot of a ridge of the Andes, at S. lat. 13° 41′, and by the road of Guamanga, 550 miles S. E. by E. from Lima. Similar to other Peruvian provinces, that of Cuzco is far from being easily defined, but as laid down on our maps, it is bounded west by Guamanga and Arequipa, south-east by the United provinces of Rio de la Plata, and the lake of Chucuito, and north by a country yet in the possession of native Indian tribes. It is about 350 miles long from north to south, being between S. lat. 12° 50′ and 17° 50′, with a mean width of 135, and area 47,250 square miles. Aggregate population in 1795, 216,382, of whom 31,828 were whites.

The province of Cuzco is one of the most diversified, not only of Peru, but of the earth. High and precipitous chains of mountains are separated by deep vallies or by elevated plains, from which the Jambari, Vilcabamba, Apurimac and other rivers flow to the north, and many brief but rapid currents rush into the lake of Chucuito. The latter is a Caspian on a small scale, of about 180 miles from south-east to north west, and with a very irregular outline. It is in fact a mountain basin, similar to to Bohemia in Europe, and Mexico in North America, with the exception, that the two latter have their outlets broken, and the former has no issue for its imprisoned waters. Between lake Chucuito, and the Pacific Ocean at S. lat. 16° are the extreme sources of the Lauricocha, or main stream of the Amazon.

Arequipa closes the Peruvian provinces to the south, having the Pacific Ocean south west, Lima north-west, Guamanga north, Cuzco north-east, the United Provinces of Rio de la Plata south east, and the Chilean desert of Atacamas south. This province is a long and narrow strip along the Pacific Ocean between S. lat. 15° and 21° 27′, but extending from south-east to north-west, the actual length exceeds 600 miles; breadth inland not exceeding a mean of 40 miles; the area 24,000 square miles.

Arequipa, the capital, is an inland town of considerable note, containing a population of 24,000 souls, situated at the western foot of the Andes, at S. lat 16° 20′. The commercial capital is Arica on the Pacific, through which, a trade is maintained with the inland provinces. It stands at S. lat. 18° 20′. The slope of Arequipa entire, partakes so much of the general character already given of the whole Pacific coast of Peru, as not to need much farther description. It may suffice to observe, that along the streams agriculture is more skilfully and extensively pursued, than it is on the plateau of the Andes, where the soil is more productive, but where mines of the precious metals supersede the far more useful and really more enriching labours of the field.

In 1794, there were in the intendancy of Arequipa, an aggregate population of 136,024, of whom 39,357 were whites, 66,609 Indians, 17,797 Mestizoes, 7003 Mulattoes, and 5258 slaves.

Summary table of the population and relative provincial extent of Peru in square miles.

Provinces.	Agg'te Pop'n.	Extent in sqr. mls.
Truxillo	72,000	230,176
Tarma	26,000	200,928
Lima	32,000	146,924
Guancavelica	8,000	30,917
Guamanga	18,000	111,256
Cuzco	47,250	216,382
Arequipa	24,000	136,024
	227,000	1,072,607

How or in what manner the population of Peru has been affected by recent revolutionary movements we are unable to state, but according to Baron Humboldt, the inhabitants of that country amounted to 1,400,000, about 1820. In 1794, when the estimates were made from which the preceding summary was formed, the components of the people of Peru were, whites 136,311, Indians 608,911, and the residue Mestizoes, Mulattoes and slaves. The proportions given by Humboldt, are nearly the same, and it is probable, have not varied materially in the last 34 years.

Since 1821, Peru has been definitively separated from Spain, but the political condition of the former is far from fixed, nor have we document for its actual condition.

When we read florid descriptions of the tropical mountain vallies and plains of America, we are seduced from a consideration of their great disadvantages. In the table lands of Mexico, Central America, Colombia, and Peru, a perpetual summer may be said to reign, but these gardens are separated from the continent and each other, by steep and excessively lofty mountains, and by deep and precipitous vallies. Here, nature seems to have opposed equal barriers against water or land intercommunication. To construct roads over the chains and vallies of the Andes, or the Anahuac, demands a labour almost beyond all human power, and to open the channels of the rivers to navigation is a task still more appalling. If we turn our attention to a map of Peru, and the south-western provinces of Colombia, we see the great fountains of the Amazon rising near the very shore of the Pacific, through 16 degrees of latitude, and gradually uniting, trace a direct channel to the Atlantic Ocean. But when we learn, that to reach the navigable bosoms of these rivers, we must fall from 2000, to 12,000 feet, we also learn the painful truth, that ages must elapse before united wealth and physical force can render those flowing masses of water available to the inhabitants of the elevated plains of the Andes.

Since the discovery of America, the commerce of these peculiar regions has been conducted by package transportation on the backs of animals, with but little exception, and the features of the earth indicate the perpetuity of this caravan mode of conveyance.

Thus far we have surveyed the vast provinces of Colombia, Brazil, the United Provinces of Rio de la Plata, Chile, and Peru, and to complete the view of civilized settlements on South America, we return to the shores of the Atlantic Ocean.

Guiana—Guyana, taken in the utmost extent, designates a space in South America, stretching south-eastward from the Orinoco, to the Oyapok river, having the Atlantic Ocean north-east, the Orinoco river north-west, and the Brazillian provinces west, south-west, and south. Thus extended, Guyana would extend upwards of one thousand miles from east to west, with a mean breadth of at least three hundred miles, but under the head of Colombia, the extensive country between the Orinoco, Atlantic Ocean, and the Pomaron and Essequibo rivers, has been already noticed. Therefore, under the present article, we have to review the region particularly called Dutch, French, and English Guyana, comprising a tract of 450 miles by 300; area 135,000 square miles.

Of the foregoing superficies, the inland, and far greater part is not only unsettled by civilized colonies, but remains unexplored. The coasts are low, and the river banks in many places liable to inundation, and the very gradual acclivity of the country from the ocean, permits the flow of the tides far inland. From every description of the ocean border of Guyana, it bears a very striking similitude to that of Louisiana; on both, sand hills parallel to the shore, and of no great, if any elevation above high tides, seem to indicate accretion from the alluvion of the ocean. The great current of rotation from Africa, washes along the coast of Guyana, and no doubt contributes to the deposit of sand. The general range of Guyana is from east to west, as is that of the mountains which separate it from the rivers flowing into the Amazon. The principal rivers of Guyana are thus determined in their course, and the Essequibo, Demerara, Berbice, Corentin, Surinam, Maroni, and Oyapok, flow in nearly a northwardly direction.

The elevation of the interior mountain chain of Guyana has been stated at 2000 feet, from which the rivers have a direct and rather precipitous course, until they fall over numerous ledges of rock, and reach the level of the ocean. The country is consequently divided into three physical sections; first, the interior, mountainous; secondly, a hilly and broken tract between the mountains and the falls; and thirdly, the sea and river sand alluvial border. This structure is essentially the same in character with that of the Atlantic slope of the United States, and proves that the far finest part of Guyana, is yet an uncultivated wilderness. In latitude, this part of South America lies between N. lat. 1° 20′ and 7° 20′, and in long. between 18° and 24° 40′ E. from Washington City.

Along the flat and in part marshy shores, the European colonies have been established. The Dutch settlements of Essequibo, Demerara, and Berbice form what is now called British Guyana. These settlements containing 10,000 whites and 80,000 negroes, line the coast from the mouth of Essequibo river to that of Berbice, inclusive, and do not extend above 100 miles along the coast. Starbrock, at the mouth of the Demerara, is the capital, and contains a population of 10,000, amid the most flourishing part of British Guyana. The town and settlements of Essequibo, and Poumaron are of inferior importance. The settlers generally reside on their farms, and are many of them excessively wealthy. Whole population 3151 whites, 3220 people of colour, and 96,349 slaves.

Surinam follows the Dutch British settlement of Berbice, and including the whole of what is yet Dutch Guyana, stretches in an east and west direction from the settlements of Berbice 240 miles to the Marowine river. This flourishing colony is a monument of active industry; "none of the Antilles," says Malte Brun, "are so extensively or so well cultivated." Parmaribo, or Paramaribo, the capital, is built on the western bank of the Surinam. The streets are lined with orange, shaddock, tamarind, and lemon trees, bearing mingled bloom and fruit perennially. In 1815, the whole number of inhabitants in Dutch Guyana amounted to 2029 whites, 3075 people of colour, and 51,937 slaves; the whole 57,041.

Cayenne, or French Guyana, is of very inferior consequence to either the British or Dutch part. Nominally reaching from the south-east to north-west 200 miles, from the Oyapok to the Marowine river, the actual settlements are restricted to the banks of the small river Cauron. The whole number of inhabitants has been estimated at 2000 whites, and 16,000 negroes, mulattoes, and mestizoes.

We thus find in the three sections of Guyana only 7180 whites, and 170,581 people of colour and slaves; in all 177,761.

If the whole region from the mouth of the Oyapok to that of the Poumaron is viewed on a map, it will be perceived that the extremes differ about three degrees of latitude, and lying so far within the tropics as to approach within 5 degrees from the equator, that but little difference of climate or season could exist between the parts, but such uniformity of temperature does not exist. The dry season lasts at Surinam from the end of July to November, and the rainy season corresponds to the winter months of Europe; but the summer and winter, or rainy and dry seasons, begin at Cayenne about two months earlier than at Surinam. At Cayenne, Fahrenheit's thermometer does not at any time rise above 82.3°, and in the rainy or winter season ranges below 75.2°. The climate of Surinam is still milder. Mr. Stedman, however, represents the seasons as variable as in any part of Europe. The influence of northern winds during the rainy season, and of the east and south-easterly breezes in the dry months, are felt along the whole coast of Guyana. The effect on health of such a country is obvious; malignant and intermittent fevers must prevail, and extend their influence more or less from local circumstances; and from what has been stated, it is rendered certain that the fine hilly tract of Guyana above the falls of its rivers, must in the progress of settlement constitute the most healthy, agreeable, and best populated part.

The vegetable productions of Guyana are such as are superinduced by the soil and climate. Sugar, coffee, and indigo are staples of commerce. The fruits of Europe, except the grape, fig, and pomegranate, do not flourish: the orange, lemon, sapota, guava, amiona, and others, abound. The forests of Guyana are proverbially dense and specifically numerous.

From those parts of this great continent where civilization has at least commenced, we now turn to that lengthened peninsula and insular group, which protrudes far into the southern temperate zone This extensive region, bounded north by Chile and the province of Rio de la Plata, stretches from the river Colorado, S. lat. 40°, to Cape Horn, S. lat. 56°. or through upwards of one thousand one hundred miles north and south. The width varies from 400 miles on the north to a point to the south, but will average a breadth of 400 miles, with an area exceeding 440,000 square miles. Even the coasts are not very accurately known, and the interior has been but defectively explored. The ignorance, or the indifference of geographers, has designated these southern regions under the names of Patagonia, Terra Magellanica, and Araucania, each applied vaguely. The latter term, however, admits of some precision when applied to the country south-east from Chile, and south-west from the provinces of Rio de la Plata.

When the Spaniards, early in the sixteenth century, entered Peru, their sanguinary career swept with unequalled rapidity over Peru and over northern Chile. They advanced without fear of successful opposition until they crossed the river Maule, when they at once encountered an enemy not only their equals, but superiors in the art of war, and though nearly three centuries have elapsed since the Spaniards penetrated into southern Chile, their posterity have rather retrograded than advanced in Araucania. Under the head of Chile, we have found the provinces of that republic bounded by the Biobia river, with the exception of the detached achipelago of Chiloe. On the Atlantic side of the continent, the civilized settlements do not extend beyond lat. 38°. The intermediate country, therefore, between southern Chile and the extreme southern settlements of Buenos Ayres and Mendoza, and all beyond to Cape Horn, is in possession of the native Indians. These hordes, few in number, but fierce and warlike, are inimical to the Spaniards, and interrupt the communication between Buenos Ayres and Patagonia. In April, 1822, a commissioner was sent by the provincial government of Buenos Ayres, in order to negotiate a purchase of a large part of the Indian territory. A conference was had with the caziques, but the high price demanded defeated the negotiation. The following extract shows the relative situation of the Indians and whites, and the ultimate views of the latter at Buenos Ayres. "The Indians who belong to these chiefs, (the caziques who met the commissioner) are seven feet in height, naked half way down the body, and painted, wearing leather hats with a plume of feathers. Most of them agreed to sell lands, but demanded for them silver to an immense amount. Owing to this, and to the opposition made by the Indians called Rangueles, who belong to Chile, and are constantly inimical to peaceful measures, influencing, by their courage, all the other Indians; that Congress, or *Parlimento*, as they call it, produced no advantageous result, as to the laudable idea of *buying* those countries, and not taking them away by *force*. In consequence of this failure, no choice is now left to the government of the United States, but to resort to *violence;* which Buenos Ayres will the more easily carry into execution, as the number of all these barbarians does not exceed 8000 men, armed with slings and lances, with no other advantage than the rapidity of their evolutions, which they derive from their dexterity on horseback."*

It would be useless to swell our necessarily brief notice of Araucania and Patagonia with barbarous names which time and civilization must obliterate. This most protruded continental section of the earth terminates in a broken, barren, and desolate group of islands. separated from the main land by the celebrated straits of Magellan. They were discovered, passed, and named in 1519, by

* Account, Historical, &c. of the United Provinces of Rio de la Plata, page 185.

Magelhaenes, a Portuguese navigator. The tortuous length of these straits is about 450 miles, and their navigation difficult and dangerous. The cold sterility and desolation of these Magellanic regions have been no doubt too greatly exaggerated. More recent and correct information has removed much of the terrific from the face of nature along its shores, and has shown the navigation much less difficult than was formerly supposed. No permanent civilized establishment has yet been made on the straits of Magellan, though perhaps no other colonial settlement could be made more beneficial to the commercial interests of mankind. In the present state of human affairs, the imperfectly known seas and islands which environ southern Patagonia are regarded as the terror of seamen, and the sources of prolific fable in physical geography.

We have reserved to close this account of the colonized parts of the continent of South America, a notice of the province recently contended for by Brazil and the United Provinces of Rio de la Plata.

Banda Oriental, so called relatively to Buenos Ayres and Entre Rios, is bounded by the Rio de la Plata south, the Uruguay river west, the river Ybicui north, the Rio Yaguaron and the Laguna Merin north-east, and the Atlantic Ocean south east. It extends from S. lat. 29° 30′ at the entrance of the Ybicui river into the Uruguay to Punta del Este, S. lat. 34° 59′, or through 329 minutes of latitude, equal to 380 miles nearly; the mean breadth from east to west about 200 miles; area 76,000 square miles. If a temperate latitude, a fruitful soil, and commercial facilities by ocean and rivers are taken into view, no other equal section of the earth can exceed the Banda Oriental. Without regarding minute bends, it is bounded 350 miles by the most navigable part of the Uruguay; by the great Bay of Rio de la Plata, in all its length from Punta Gorda at the mouth of the Uruguay to Cape Maldonado, 215 miles. Along the Atlantic Ocean, from Cape Maldonado to Fort de Santa Teresa, 100 miles, and thence with but a short land interval, by the Laguna Merin, and the Yguaron and Ybicui rivers, to the entrance of the latter into the Uruguay.

The central part of this fine country is a table land from which flow several rivers of considerable magnitude. The Laguna Merin is the estuary of the St. Luis, Cebullati, Olinar, and Yguaron, the waters of which, collected in the Merin, are discharged by the strait of Sangradero in the Laguna de los Patos, and reach the Atlantic by the Rio Grande. Beside the Uruguay, and many rivulets, the bay of Rio de la Plata receives at Punta Espinello, seven miles N. W. from Monte Viedo, Rio Santa Lucia, from the interior settlement of Minas. The most considerable stream, however, of the Banda Oriental, the course of which is entirely within the country, is the Rio Negro. This stream heads with the Yguaron, and Ybicui, and by its most considerable southern branch the Rio Yic, with the Santa Lucia and Cebullati. By a comparative course of three hundred miles to the south-eastward, it falls into the Uruguay, 80 miles directly north from the city of Buenos Ayres. Above the Rio Negro, again issue from Banda Oriental, the Guegissay or Quequay, Rio Diamon, and Arapey rivers.

Without any assistance from art, the streams of the Uruguay, Negro, Cebollati, Ybicui, and Santa Lucia, are navigable far into the interior. A ridge of high land, winds through the whole length of the Banda Oriental, called the *Cuchillo Grande*, (*Large Knife*) from which the rivers have their sources.

As in all other Spanish and Portuguese American colonies, the settlements in Banda Oriental are detached, and in many instances distant from each other. The principal inhabited places are Monte Video, Colonia, Santa Lucia, Camelones, San Jose, San Carlos, Soriano, and Cerro Largo; which are all towns: and the villages are, Toledo, Pando, Rocha, Penarol, Piedra, San Salvador, Minas, Florida, Porongos, Colla, Bacas, Vivoras, Espinilla, Mercedes, Piasandu, and Hervidera.

The climate of the Banda Oriental is temperate and humid in general. The winds from the ocean, which are those from south-west to north-east inclusive, are productive of rain, those from the western side of the meridian are dry. In particular, the N. W. called *passageros*, are invariably dry land winds. The salubrity of this country has been the boast of its inhabitants and of strangers.

In the year 1810, the population of Banda Oriental was between 60 and 70,000 souls, and at present, 1829, it is probable, exceeds 70,000. Monte Video, the capital, stands on the north side of the Bay of Rio de la Plata, at S. lat. 34° 55′, two degrees of long. and diagonally 132 miles, a little S. of E. from Buenos Ayres, and 80 miles almost directly west from the mouth of the Bay at Punta del Este. The width of the bay from Monte Video S. W. to Punta de la Memoria, is 60 miles. The city stands on a small open bay, and is generally represented as containing about 20,000 inhabitants. The original settlement of the capital and province is disputed between Spain and Portugal, but the general and particular names being Spanish, afford an almost conclusive evidence in favour of the former. The dispute was national and of long standing, and when Brazil became an empire under the eldest son of the king of Portugal, that monarch risked a war with Buenos Ayres, in preference to yielding the claims of his parent country to the Banda Oriental. This war terminated by a treaty signed at Buenos Ayres, August 27th, 1828, and the following articles of the treaty show the disposition made by the parties of the object of contention.

"Art. 1.—His majesty the emperor of Brazil, declares the province of Monte Video, at present called the Cisplatane, separated from the territory of the empire of Brazil, in order that it may constitute itself into a state free and independent of any nation whatever, under the form of government which it may deem most suitable to its interests, wants, and resources.

"Art. 2.—The government of the Republic of the United Provinces concurs in declaring, on its part, the independence of the Province of Monte Video, at present called the Cisplatane, and in its being constituted into a free and independent state, in the foregoing article."

The 4th article provides for the formation of a representative convention Congress, by deputies elected from the Banda Oriental and by the city of Monte Video; and the 5th, 6th, and 7th articles provide for the formation of a provisional government, and constitute the Congress a Convention to form a permanent Constitution. The remaining 12 articles regulate the various details relating to the troops, rights of removal, and of property, delivery of prisoners, &c.

With the ultimate proceedings under the treaty, we are unacquainted; but are enabled to regard the Cisplatane province, or Banda Oriental, as at least nominally an independent republic of South America.

We have, as far as material has been collected, and with due regard to our restricted limits, taken a general survey of the continent of South America, and close the article by a notice of the islands, contiguous to and usually regarded as appertaining to that continent.

Tierra del Fuego, already briefly noticed under the head of Patagonia, is a large but desolate irregular island, separated from the continent by the Straits of Magellan. It is three hundred miles in length from the Straits of Le Maire, to Black Cape. The surface is mountainous and contains one or more active volcanoes, whence the name, Tierra del Fuego, or Land of Fire. The main island is environed with many smaller ones of similar mountainous and desert character.

It is a common error to suppose that Cape Horn, the *Ultima Thule* of South America, is a part of the island of Terra del Fuego: on the contrary, Cape Horn, almost exactly on S. lat. 56°, is the extreme southern point of Hermit Island.

Between the western outlet of the straits of Magellan, in S. lat. 53°, and Maulin Bay, separating Chiloe Island from Chile, in S. lat. 41° 40′, through upwards of eleven degrees of latitude, the western coast of South America is much broken by islands and small peninsulas; amongst the former, the most worthy of notice are Ancon, Madre de Dios, and St. Martin's, between S. lat. 49° 20′, and 52°, and between the Gulf of Santissima Trinidad, and Cape St. Isabella. Cape Corsa separates the Gulf of Santissima Trinidada from Campana Island, extending to S. lat. 48°. The gulfs of Chonos, Guytecas, and Chiloe, form in fact one lengthened bay from the peninsula of Three Mountains to Maullin Bay, or for about 250 miles. This labyrinth is filled with numerous islands, the principal of which, Chiloe, was noticed under the head of Chile.

Immediately to the north of the western entrance of the straits of Magellan is the peninsula of Lobos, terminating to the north-west in the Cape of Santa Isabella, and again between S. lat. 45° 22′ and 46° 41′, extends the true peninsula of Three Mountains, attached to the continent by a very narrow neck of land.

It is very remarkable, that leaving the Bay of Maullin, and advancing northward, that there is not along the coast of South America a single island worthy of notice, or a peninsula from Chiloe to the Pearl Islands in the Gulf of Panama, in a distance, following the coast, of four thousand miles.

The islands of the Pacific, Juan Fernandez, Ambrosio, St. Felice, and the Gallapagos, have been by geographers attached to South America, but the relative distance renders the connexion doubtful. A similar remark might also be made with respect to the Malouine or Falkland's Islands in the southern Atlantic, but we may notice the former from their historical notoriety. The group crossed by S. lat. 52°, lies about 110 miles a little north of east from the straits of Magellan. There are several smaller, but only two of any considerable size are relatively called East Island and West Island, separated by a strait, the San Carlos of the Spaniards, or Falkland's Channel of the English. No wood, and but a scanty vegetation of any kind grows on these islands, except grass, which is luxuriant. They are in reality, though long contended for between Spain and Great Britain, mere barren rocks or marshes, the residence of Phoci and wild fowl.

Though the Atlantic coast of South America is lined in many places by islands, they are mostly very narrow and separated from the main shore by very confined channels. From the straits of Magellan to the equator, the only island of considerable extent is that of Joanes, between the mouth of the Amazon and Tocantin; lying between the equator and 1° 30′ S. Length from N. E. to S. W. 180 miles. Its form is oval, and comprises an area of about 9000 square miles. There are several villages on its shores.

Trinidad, off the mouth of the Orinoco, is perhaps the far most important island of South America, to which with Tobago it certainly belongs. The ranges of mountains, and the longitudinal position of Tobago and Trinidad, connect them with the Sierra de Paria. The latter lies between N. lat. 10° 06′ and 10° 51′; and excepting four sharp and narrow capes, the form is nearly a square of 40 miles each side. The outlines of Trinidad are peculiar; from each angle of the square protrudes a point, to the south-east Point Galeota, to the south-west Point Yeacas, north-west Point Coroval, and north-east Point Galera.

The two western points of Trinidad, Punta de la Pena, Cumana, and the Delta of the Orinoco, nearly enclose the gulf of Paria, a sheet of water, of one hundred miles from east to west, with a mean breadth of sixty miles. This gulf opens to the north, between Trinidad and Cumana, by the channel of the Dragon's Mouth, and towards the Orinoco by the Serpent's Mouth. It was through the Dragon's Mouth, that Columbus, in 1498, entered the gulf of Paria, and gave the island the name of Santissima Trinidad. It was first colonized by the Spaniards, and with casual interruptions from the English and French, continued a Spanish colony to 1797, when it was invaded and taken by the English, and by the treaty of Amiens, March 27th, 1801, it was finally ceded to Great Britain.

The products of Trinidad are cotton, sugar, coffee, indigo, and ginger, with a great variety of tropical fruits, and maize. The climate is moderately healthy, with a soil of boasted fertility. Existing population uncertain.

Tobago, lying 23 miles north-eastward from Punta de Galera, is evidently a continuation of the Sierra de Paria, and of the northern ridge of Trinidad, is a small island thirty miles from south-west to north-east, with a mean breadth of seven miles. On this confined spot, a few years since, resided 2574 whites, and 15,426 negroes. Tobago was one of the discoveries of Columbus, in 1498, and underwent perhaps, more changes of masters, than any other American island. Finally, in 1814, it was ceded to Great Britain. Commercial staples nearly similar to those of Trinidad.

Margarita, island and province of Colombia, cut into two nearly equal parts by N. lat. 11°, is separated from the coast of Cumana by a channel of 12 miles width. Its greatest length from east to west is 40 miles. The very irregular outline renders an estimate of the surface difficult, but may be stated at 350 square miles. In 1827, it contained a population of 14,690, of whom 3000 were contained in Asuncion, the capital.

Curaçoa, Buenaire, and Oruba, are three islands lying off the province of Coro in Colombia, but belong to the kingdom of the Netherlands. Curaçoa, the principal island, is situated at from N. lat. 12°, to 12° 18′, long. 8° E. from Washington city. Buenaire lies 60 miles easterly, and Oruba an equal distance westerly from Curaçoa. The whole three may amount to a length of 70 miles, with a breadth of seven or eight, with an area of 500 square miles, and of which nearly one half would be in Curaçoa. It was perhaps only the Dutch, of all the European nations, who attempted colonies in America, who could have succeeded in Curaçoa. The land is arid and sterile; the soil, what little does exist, thin. Yet on this ungrateful tract, there were in 1815, whites 2781, free coloured persons 4033, and 6026 slaves, in all 12,840.

Williamstadt, the capital, is represented as one of the most magnificent, clean, neat, and convenient towns in the whole West Indies. Sugar and cotton have been successfully cultivated on Curaçoa, but on Buenaire and Oruba, the rearing of stock has been preferred to agriculture by the inhabitants.

Summary Table of South America.

The political sections taken in the order of the preceding description.

Political Section.	Sq. miles.	Population.
Republic of Colombia,	1,180,000	2,396,404
Empire of Brazil,	3,000,000	4,000,000
Republic of Rio de la Plata,	*1,100,000	1,000,000
Chile,	90,000	1,226,000
Peru,	227,000	1,072,607
Guyana,	135,000	177,761
Patagonia and Araucania,	440,000	500,000?
Banda Oriental,	76,000	70,000
Islands,	44,000	87,690?
	6,292,000	10,530,462

We have completed our brief survey of the most interesting, because the most fruitful and healthy peninsula of the earth, and we find at its conclusion the striking moral phenomenon, that on much more than one seventh part of the productive soil of this planet, there exists only ten and a half millions of human beings. On a surface where the whole existing human species could be subsisted, there is a little fraction above 1½ human beings to each square mile; or about 16 to each 100 square miles.

If we compare South America to Europe, and take the respective climates into the contrast, it is safe to say that the former could support a population double to that of the latter. Europe, on about three millions of square miles, has an existing population of two hundred millions; therefore, if South America was peopled equal to Europe, it would contain four hundred millions of souls.

The actually inhabited part of the United States of North America, amounts to about 600,000 square miles, on which there is an aggregate of, say thirteen millions of persons: the surface peopled nearly equal to one tenth part of South America, consequently, if the latter had a population even equivalent to the former, it would then have ONE HUNDRED AND THIRTY MILLIONS OF SOULS.

For a more full account of the the Provinces, Cities, and Islands of South America, see our articles AMERICA, Vol. I. p. 578; ARAUCANIA, Vol. II. p. 285; AREQUIPA, 321; BRASIL, Vol. IV. p. 404; BUENOS AYRES, p. 778, and Vol. V. p. 1; CARACCAS, Vol. V. p. 318; CHILI, Vol. VI. p. 19; CUENCA, Vol. VII. p. 324; CURACOA, p. 349; CUSCO, 372; TIERRA DEL FUEGO, Vol. IX. p. 492; NEW GRANADA, Vol. X. p. 54; GUAMANCA, p. 139; GUAYAQUIL, p. 141; GUIANA, 144; LIMA, Vol. XII. p. 66, PATAGONIA, Vol. XV. p. 398; PERU, p. 504; QUITO, Vol. XVI. p. 296. SOUTH CAROLINA, one of the original thirteen United States of America, bounded south-east by the Atlantic Ocean, south-west by Georgia, and north and north-east by North Carolina. It has an ocean border from Little Inlet to the mouth of Savannah river, 185 miles;—along Savannah, Tugaloo, and Chatuga rivers, in common with Georgia, 270 miles;—along the southern boundary of North Carolina, 300 miles;—entire outline 755 miles.

The greatest length of this state is from the eastern angle on the Atlantic Ocean, at Little River Inlet, by a line extending N. W. by a westerly direction to the western angle of Picken's district on the Chatuga river, 275 miles. The area of South Carolina has been generally and greatly underrated. Measured carefully, on the recent and excellent state map by the rhumbs, it gives a result of very near 33,000 square miles. The mean width is 120 miles. The state lies between N. lat. 32° 01′ and 35° 10′, and in long. from 1° 44′, to 6° 20′ W. from the meridian of Washington City.

Immediately south-west from the Susquehanna river, the physical geography of the Atlantic slope gradually assumes a separation into three zones, indeterminate in separating lines, but fully apparent in Maryland, more distinct in Virginia, and completely developed in North Carolina, South Carolina, and Georgia. These three zones are, first, from the ocean extends a level sea sand strip about 60 miles wide, and stretching along the whole front of South Carolina, 180 miles; second, a hilly and higher, but parallel and contiguous band of nearly equal breadth; and lastly, a still more broken and elevated tract, comprising the residue of the state. These three zones may be specifically designated, the south-east or sea-sand border; the middle, sandy and hilly section; and lastly, the north-western or mountainous portion.

The zone near the Atlantic rises very gradually from the Ocean level, near which it is marshy, and is intersected by a net-work of interlocking streams, receiving the tide, though none are sufficiently deep to admit the navigation of large vessels. Receding inland, the surface seems to emerge from the swamps, and hills of moderate, but increasing elevation, appear. The interlocking of the river channels ceases before reaching the middle zone. In a state of nature, the Ocean zone of South Carolina was covered with a most dense forest, in which the gigantic Palm *Arec oleracea*, raises its majestic stem. The tide in the principal rivers passes over the first to the middle zone.

Great part of the middle or central zone of South Carolina has been called "*the Sand Hills.*" Here pine forests abound, the productive soil lying mostly along the rivers. This central belt passes the tides and reaches the falls of the rivers. In a geological view, the two outer zones have been considered alluvial. The exterior one on the Ocean is truly so, and much of the alluvion recent, but the second must, in regard to formation, be referred to a very remote period, though below the falls of the rivers, the whole surface exhibits full evidence of submersion. The great ledge of rock over which the rivers of the Atlantic slope of the United States are precipitated, and which in every case arrests the tide south-west from the Hudson, crosses the Great Pedee near Sneadsborough, and almost on the line between North and South Carolina. Continuing south-westerly, the rock ledge is passed by the Wateree near Camden, the Congaree at Columbia, immediately below the junction of the Saluda and Broad rivers, and by the Savannah at Augusta, where it quits South Carolina.

Above this ledge and the river falls, commences the high hilly or mountainous zone, and though the change is not in many places very rapid, yet a few miles to the north-west exhibits the salutary transition. Below the falls the aspect of nature is more or less monotonous, and near the outer border vies with the ocean in depression and level: but above, receding towards the Appalla-

* We have taken the superficies and population of the Provinces of Rio de la Plata in round numbers.

chian chain, hills meet the eye, in a succession of form and elevation, round, bold, and swelling in their contour. The rivers wind through vales, variegated and gently undulating, and where under the hand of culture, smiling in all the gaiety of field, garden, orchard, and meadow.

Agriculture in South Carolina has been controlled effectually by soil and climate, and the latter regulated as much or more from relative elevation of surface as by mere parallels of latitude. The extremes of the state, from the marshy surface of Beaufort, Colleton, and Charleston districts, to the mountainous tract embraced by Spartanburg, Greenville, and Picken's districts, differ three degrees of latitude, and at least 1000 feet in relative level. The difference of height is more than equal to two degrees of latitude in effect on aerial temperature; therefore, the upper and lower section, or what in South Carolina is the same in position, the northern and southern part, differ in temperature equivalent to five degrees of latitude.

Below lat. 33°, the orange, lime, and lemon come to perfection; the fig is reared in great part of the state. Apples and peaches abound in the more northern and higher parts. As staples, rice and cotton have been long the principal objects of agriculture in that state. The former is limited by climate, and the necessity of irrigation, to the sea border, but the latter has a range commensurate with the entire superficies of the state. The cotton of South Carolina presents, however, two distinct varieties. "*The Sea Island, or black seed*," is limited as its name imports; but the green seed, or common cotton, is cultivated in other parts.

Rice and cotton do not preclude the cultivation of grain. Indian corn is reared in every part, and wheat, rye, oats and barley in the interior, and particularly on the high mountainous section. Sugar cane has also been cultivated to advantage in Beaufort district.

Taken as a whole, South Carolina is a fruitful and prosperous state. The natural vegetation combines the pines and palms with the oaks and hickory, and in cultivated plants, the sugar cane and orange to the wheat and apple. Though the sea coast offers to commerce no harbours of the first class, it abounds with those which admit commercial, and exclude large vessels of war. Similar to many other sections of the Atlantic slope, the rivers of South Carolina are more navigable for boats at a distance from, than near the sea coast; and to aid internal navigation, two very important and several smaller canals have been completed.

The Santee Canal, made to effect a direct water communication between Charleston harbour and Santee river, leaves the latter at Black Oak Island, or rather opposite that island, and crossing the intermediate swamp in a direction of south south-easterly, enters the western branch of Cooper river about thirty miles, in a direct line, almost due north from Charleston. Length of the canal 21 miles. This is the most extensive artificial water channel yet executed in the United States south of Virginia.

Before entering the Atlantic ocean, and 15 miles inland, Santee river divides into two great arms, called locally and relatively, North Santee, and South Santee. From the former to Winyaw bay, or the estuary of Pedee river, there is an intermediate marshy peninsula of 12 miles wide. To connect the two rivers, and obviate the danger of the open ocean, a canal called Winyaw Canal, 6 miles in length, has been opened across the peninsula, from Winyaw bay to Kinlock's creek of Santee river.

Above the river falls, side cuts have been made to meliorate the navigation of the Saluda, Broad, and other rivers. A rail road from Charleston to Augusta in Georgia has been commenced, and other similar works projected.

The natural channels are numerous and extensively navigable. Great Pedee river rising on the line between Virginia and North Carolina, and traversing the latter, is a river of upwards of two hundred miles comparative course, and of considerable volume where it enters South Carolina, and within which it receives from the west Lynche's and Black rivers, and from the east Waccaman river. The Pedee also, by its northern and main tributary the Catawba, rises in North Carolina, and is a fine navigable stream at its entrance into South Carolina. Between Charleston and Columbia, the Congaree joins the Pedee with an equal if not superior body of water. The former drains the far greater part of the north western section of tho state, and is navigable far above Columbia in both its constituents, the Saluda and Broad rivers. The Savannah, forming the south-western boundary of the state, is navigable to the entrance of the Tugaloo.

Along the marshy sea border, though none of the channels are deep, they are numerous, and amongst the principal entrances may be named, advancing from N. E. to S. W.: Georgetown entrance or Winyaw bay, North Santee, and South Santee; CHARLESTON HARBOUR, Stone River, North Edisto, and South Edisto; St. Helena Sound, Port Royal entrance, and Savannah river.

History and Progressive Population.—The name of Carolina is derived from that of Charles IX. king of France, and was imposed from an abortive attempt made during the reign of that monarch, by the French to colonize that part of America. The first actual settlement by an English colony in the territory now included in South Carolina, was formed in 1680, though partial attempts had been made as early as 1670. At the former epoch a few settlers fixed on Oyster Point, between Ashley and Cooper rivers, and laid the foundation of Charleston. Conflicting grants were made by the English crown to the country, and contributed to retard settlement. In 1662, Charles II. granted to Lord Clarendon and others, all that zone of North America from N. lat. 31° to 36°, and two years afterwards the boundaries were extended to 36° 30′. Locke's scheme of government made the previous confusion a chaos, which was in part reduced to order in 1719, by the permanent separation of the colony into two parts, which were called relatively North Carolina and South Carolina. South Carolina now advanced slowly but steadily. The cultivation of useful vegetables was encouraged. Rice was first introduced into the colony about the year 1695. Indigo followed, (cotton. now the great staple of the country, was introduced at a later period) and South Carolina, though frequently harassed by Indian warfare, flourished until checked by the Revolutionary war. In that great moral contest this state was an illustrious actor and a deep sufferer. Her fields and waters were made classic by being the theatre of many of the most remarkable events of that war. Many of her sons distinguished themselves as patriots and heroes, and some were made martyrs to the cause. To mention no others, the names of Hayne, Marion, Sumpter, and Lee, threw a halo of glory over the state. The character and actions of Marion, give indeed to the history of the southern campaigns the richness of the epic, with the solid grandeur of reality.

In 1790, the population of South Carolina amounted to 240,073; in 1800 to 345,591; in 1810 to 415,115; and in 1820, to 501,154. This gives an increase of 209 per cent. very nearly, in 40 years. In our review of the natural subdivisions of the state, three zones were noticed, and it is very remarkable, how much the relative castes depend upon natural features of soil. With a view to render this important statistical fact obvious, the subjoined table was calculated.

Natural Section	Area in Square Miles.	Whites.	Free col'd Perso	Slaves.	Aggregate.	Pop'n to the Square Mile.
Alluvial,	9,000	43,241	4,451	132,637	180,329	20
Hilly,	13,000	101,537	1,801	89,013	192,351	14½
Mountainous,	11,270	93,114	553	34,807	128,474	11½
Amount,	33,270	237,892	6,805	256,457	501,154	15

This table exhibits the comparative density on the different zones, and the respective numbers of each caste, and is the only instance in the United States where, in any state, the Africao race preponderates.

Education.—For the higher branches of education, the principal institutions of this state are the Charleston College at Charleston, and the South Carolina College at Columbia. This latter institution has been established and sustained by legislative bounty. The building, library, and philosophical apparatus, including some necessary repairs, have absorbed 200,000 dollars, and to this may be added an annual appropriation of 15,000 dollars.

Free schools are also supported at the expense of the state. In 1828 the commissioners of free schools reported the establishment of 840 schools, in which were taught 9036 scholars, the cost of which was 39,716 dollars; and in 1829 the appropriation to this object was 37,200 dollars.

Government.—The existing Constitution of South Carolina was adopted June 3d, 1790, and under the authority of the 11th article, was amended by the Legislature, December 17th, 1808, and on December 19th, 1816.

The Legislature consists of two houses, under the title of General Assembly. The senators are chosen for four years, and are divided into two classes, one of which is elected biennially. No person is eligible to a seat in the Senate, unless he is a free white man of the age of 30 years, and hath been a citizen or resident in the state five years previous to his election; he may be elected whether resident in or out of the district for which he is chosen; but if a resident of the district, he must be legally seised and possessed in his own right, of a settled freehold estate of the value of three hundred pounds sterling, clear of debt, and if a non-resident in the district, he must be in like manner possessed of a settled freehold estate, in the district, of the value of one thousand pounds sterling.

The House of Representatives is chosen biennially, the qualifications for membership in which require the individual to be a free white man twenty-one years of age, a citizen and resident of the state three years previous to his election; if a resident in the election district, he must possess a settled freehold estate of five hundred acres of land and ten negroes, or a real estate of one hundred and fifty pounds sterling, clear of debt: if a non-resident of the district, he must be legally possessed of a settled freehold estate therein of the value of five hundred pounds sterling, clear of debt.

The Governor is chosen by joint ballot of both houses of the Legislature, for a term of two years, and at the end of that term, is ineligible for the four succeeding years. He must have attained the age of 30 years, and have resided within the state and been a citizen thereof ten years previous to his election, and when elected must be seised and possessed of a settled estate within the same in his own right, of 1500 pounds sterling, clear of debt. The Lieutenant Governor is elected at the same time, continued in office for the same period, and must be possessed of the same qualifications as the Governor.

The Governor has the power of pardon after conviction, except in cases of impeachment.

The executive power is vested in superior and inferior courts directed and established by the Legislature: the judges hold their offices during good behaviour, and are only removable by impeachment.

To exercise the elective franchise in the choice of members of the Legislature of either branch, it is requisite, that the person be a free white man citizen of the state, and have attained to the age of 21 years; paupers, and non-commissioned officers and privates of the United States army excepted; must have resided in the state two years previous to the day of election; have a freehold of fifty acres of land or a town lot, of which he must be seised and possessed at least six months before such election: or not having such freehold or town lot, hath been a resident in the election district in which he offers to give his vote, six months before the said election.

By the 11th Article of the Constitution of South Carolina, it is provided that: "No convention of the people shall be called, unless by the concurrence of two thirds of both branches of the whole representation." But, the Constitution may be amended by the Legislature, when "a bill to alter the same shall have been read three times in the House of Representatives, and three times in the Senate, and agreed to by two thirds of both branches of the whole representation; neither shall any alteration take place until the bill so agreed to, be published three months previous to a new election for members of the House of Representatives; and if the alteration proposed by the Legislature shall be agreed to in their first session, by two thirds of the whole representation in both branches of the Legislature, after the same shall have been read three times, on three several days in each house, then, and not otherwise, the same shall become a part of the Constitution.

Under all these restrictions, the Constitution of South Carolina has been, as we have shown, twice amended.

For political and judicial purposes, this state, in place of counties, is subdivided into districts. In the subjoined table, the italic letters annexed to each district, show their relative situation, *e*, *w*, *n*, *s*, and *m*, stand for *eastward*, *westward*, *northard*, *southard*, or *middle*.

SOUTHWELL, or Suell, a market town of England, in Nottinghamshire, situated in a fertile and well-wooded country, on the banks of the river Greet. It consists principally of one large street, on the ro. from Newark to Mansfield; and this street is intersected by two smaller ones. The church is celebrated for the beauty and variety of its architecture. It consists of a nave with two aisles, two towers at the west end, a transept, a choir with aisles, and a chapter. It is 306 feet long. One part of the town is under civil, and the other under ecclesiastical government. The first, called the burgage, is governed by justices appointed by the Archbishop of York, and the second, called the prebendage, by prebends. The chapter exercises a peculiar jurisdiction over 28 parishes. A silk and cotton manufactory have been established here, and added to the population of the place. In 1821 the population was 573 houses, 610 families, 279 families in trade, and the number of inhabitants 3051. See Dickinson's *History of Antiquities of Southwell*, 4to. 1787.

SPA, a town of the kingdom of the Netherlands, and in the province of Liege, and celebrated for its mineral waters. It stands on a small river, at the extremity of a deep valley, and in the middle of all the romantic scenery, which occurs among wild and precipitous mountains. Its streets, which have the form of a cross, are four in number, and are regular and spacious. The accommodation afforded by the hotels and private lodging houses are, in general, good. There is a theatre and a good ball-room, and the public walks are grand though not extensive.

The springs, which are six or seven in number, are all acidulous chalybeates, an analysis of which we have already given in our article Mineral Waters. Population about 3000.

SPAIN.

PART I.—HISTORY.

In giving a short sketch of Spanish history, it cannot be expected that we should enter into any minute details. Our limits would scarcely contain a simple enumeration, in chronological order, of the many important events which have contributed, at various periods, to influence the face of this country. We shall content ourselves, therefore, with a brief statement of the different revolutions through which it has passed, with occasional observations upon its agricultural, commercial, and political state. With this view, the history of Spain may be divided into six periods.

I. Its state prior to the irruption of the northern nations.

II. While under the dominion of the Goths.

III. While subject to the Moors.

IV. While under the dynasty of Austria; and

V. While governed by the Bourbons.

Chap. I. *State of Spain prior to the irruption of the Northern nations.*

With respect to the first period, we shall pass over the fabulous legends of Berosus, who traces the origin of its inhabitants to Tubal, the fifth son of Japhet, and gives a long line of descendants, who reigned in Spain for several centuries. But whoever were the aborigines of this country, they are generally known in ancient history under the name of Iberians; and it is also ascertained

* In 1820, when the last census was taken, that part of South Carolina west of Saluda river, and N. W. from Abbeville district, composed Pendleton district; but subsequently, the latter was abolished, and out of its former limits Anderson and Pickens districts were formed.

that the Celts or Gauls, at a very early period, had formed numerous settlements to the west of the Ebro, and had become so blended with the inhabitants by intermarrying and living together, that they obtained the designation of Celtiberians.

The Greeks and Phœnicians had also planted colonies in the maritime districts, but neither of these nations penetrated into the interior, contenting themselves with the command of the sea, for the purpose of commerce, which they were allowed to hold without molestation from the inhabitants, who were glad to benefit by their trade, while they enjoyed in peace and tranquillity the produce of their own lands. This state of amity was at last interrupted by the Phœnicians, who having built the city of Gades, now Cadiz, were desirous of extending their authority over the neighbouring territory. The Spaniards, alarmed at the growing prosperity of the new city, collected their forces, and would soon have driven out the intruders, had not the Phœnicians invited the Carthaginians to their assistance, who, furnishing them with powerful succours, not only repulsed the Spaniards, but obtained the greater part of the province.

This expedition formed the commencement of the Carthaginian power in Spain. Elated with their success, and delighted with the richness of the country, and the valuable mines of gold and silver which it contained, they contemplated the conquest of the whole peninsula. For a time, however, their arms made very little progress against its warlike inhabitants, who defended themselves with great bravery and resolution, till the whole power of Carthage was directed to their subjugation. During nine years of incessant hostility, the Carthaginians penetrated into the very heart of the country, when their general, Hamilcar, was killed in a general engagement with the Vettones. His successor, Asdrubal, carried his victorious arms as far as the Ebro; and, in order to secure his conquests, built the city of New Carthage, which afterwards became one of the most considerable cities in the world.

These successes excited the jealousy of the Romans, who could not behold without alarm the rapid advance of their rivals to the entire dominion of such a country as Spain. They, therefore, willingly listened to the request of the Saguntines, who had implored their protection, and interposing in their behalf, prevailed upon the Carthaginian general to enter into a treaty, in which it was stipulated that the Carthaginians should not pass the Ebro, and that the Saguntines and other Grecian colonies should enjoy their ancient rights and privileges. No violation of this treaty occurred during the life of Asdrubal; but extending his conquests in other directions, he, either by force or persuasion, established the dominion of Carthage over the finest provinces of Spain. A few years after, however, he fell by the hands of an assassin; and no sooner had Hannibal succeeded to the command of the Carthaginian army, than he made preparations for the siege of Saguntum. Though this city was situated within the Carthaginian territory, it was expressly excepted by treaty from all hostilities; but Hannibal promised himself many advantages from its reduction. It was a key by which the Roman army could easily enter into Spain; and its possession would serve as a barrier against their future encroachments. This colony also was immensely rich, and he expected to find in it treasure sufficient to defray the expenses of a premeditated war against that rival power. The Saguntines, however, bravely defended themselves for eight months; and every inch of ground was disputed with undaunted resolution. Being at last reduced to great extremity by the scarcity of provisions, and having no prospect of assistance from the Romans, the principal senators collected in the market place their richest effects, and the contents of the public treasury, and having set fire to the pile, threw themselves into the midst of it, and perished in the flames. Many of the inhabitants soon after followed their example; and the rest, making a sally on the besiegers, were all put to the sword.

The siege, one of the most memorable in ancient history, produced a lengthened and bloody war betwixt the Romans and Carthaginians, of which Spain, for several years, continued to be the theatre. The Romans, taking advantage of Hannibal's absence in Italy, sent an army into that country. After a long contest between these rival nations, and attended with various success, the Carthaginians were driven out of Spain, and the Roman standard planted on the walls of Cadiz, which, as it was the first, was also the last stronghold which the Carthaginians held in that country. But though the Roman power was thus in a manner extended over Spain, they found it no easy matter to maintain their authority. Many of the native princes had remained calm spectators during the struggle between their invaders, while others had alternately sided with the forces of Carthage and Rome. But when they saw their country reduced to the state of a Roman province by the appointment of pretors to its government, they evinced a general disposition to throw off the yoke. The avarice, extortion, and oppression of the Roman magistrates, gave occasion to frequent revolts; but their undisciplined troops were as yet unable to cope with the legions of Rome, and every attempt to recover their liberty, served only to rivet their chains the more closely. Among these attempts, the most successful and worthy of record, was that of the Celtiberians in Lusitania, under the brave Variathus. This person, during the distracted state of his country, had been a captain of a banditti, and afterwards became one of the principal leaders of the Lusitanians. In two successive engagements he defeated the Romans with great slaughter, compelled them to shut themselves up in their strong cities, and laid the whole country under contribution. By the dexterity of his movements, he, for six years, put to flight every army that appeared in the field against him, and had drawn off many nations from their alliance with Rome. A consular army for a time checked the career of Variathus; but, soon recovering from his reverses, he defeated the consul Servilianus with the loss of three thousand legionaries, and afterwards, by a most skilful manœuvre, so hemmed in the whole Roman army, that they had no way of escape but by submission. Instead, however, of seizing this opportunity of avenging his country by their destruction, he offered peace, with this single condition, that he should keep possession of the territories now in his power without molestation from the Romans. This generous offer was joyfully accepted, and the terms were soon after ratified by the Roman Senate. Variathus thus laid the foundation of a new kingdom, which, had it not been for the treachery of his enemies, would have set bounds to the conquests of Rome in that quarter, and counterbalanced their power. But instead of the generous rivalry of arms, Rome now employed the basest of means for the accomplishment of her ambitious projects. The laws of nations, the faith of treaties, and humanity itself, were set at defiance during the subjugation of this devoted country.

She could not brook a rival within the bounds of the peninsula; and after repeated attempts to exasperate Variathus, and force him to commence hostilities, he was declared an enemy to Rome, and was soon after, at the instigation of the Roman consul, and by the promise of great rewards, treacherously murdered by his own attendants. Spain thus lost one of her noblest defenders; but she found in the citizens of Numantia heroes worthy of the liberty which they sought, but which they were not destined to enjoy.

Numantia had maintained its independence during the struggle between Rome and Carthage; and its inhabitants had resisted every attempt at its subjugation, with such daring courage, that the bravest troops of Rome trembled at the very idea of a Numantine war. The first army that sat down before its walls was completely routed and dispersed. In the following campaign 4000 Numantines pursued an army of 30,000 Romans, seized and plundered the camp which they had abandoned, killed 20,000 in the pursuit, and shut up the remainder in a rough and mountainous country. In this situation the Roman commander, seeing no way of escape, was compelled to sue for peace. This was generously granted by the Numantines, who, for the lives of 10,000 Romans, merely stipulated that they should be allowed to maintain their independence, and be reckoned among the friends of the Roman people. But, in return for this noble and disinterested conduct, the senate of Rome refused to ratify the treaty; and, lost to all sense of honour and of justice, they basely resolved, in opposition to the remonstrances of all the officers who had served in Spain, to extirpate that brave and generous people. Scipio, one of their most experienced generals, and the conqueror of Carthage, was chosen for this dangerous expedition. Unwilling to expose his men, by hazarding an engagement with the Numantines, he enclosed the city with 60,000 troops, who were protected by a wall and ditch, being resolved to reduce the inhabitants not by force but by famine. The besieged, after several brave attempts to break through the enemy's lines and obtain succours, seeing their ruin inevitable, entreated the Roman commander that he would either allow them to die like brave men in a general action, or preserve their liberty by an honourable capitulation. Scipio, however, would listen to no proposals, and insisted upon an unconditional surrender. This drove the Numantines to despair, who were now reduced to such straits that they were destroying and devouring each other; but preferring death to slavery, they set fire to their city, and either killed one another, or perished in the flames. The fall of this city was considered of such consequence that Scipio was honoured with a triumph, and had the surname of Numantinus added to that of Africanus. It consummated the subjection of Spain; for though that noble love of liberty, for which this nation was so justly famed, frequently led them to attempt their emancipation, yet they were never afterwards able to make any head against the Romans; but were at last compelled to receive the religion, the laws and the customs of their conquerors. The last who submitted were the Cantabrians, who were almost exterminated by Agrippa; and from that time Spain continued incorporated with the Roman empire until the irruption of the northern nations.

Remarks.—Before the invasion of the Carthaginians Spain was divided into a multiplicity of petty kingdoms and commonwealths, who being entirely detached, and having little communication with each other, fell one by one under the power of their conquerors. Had the Spaniards been united as one state, or mutually assisted each other, it is not probable that so brave and virtuous a people would ever have been brought under a foreign yoke. Few nations have performed such great and heroic exploits, or exhibited so many noble examples of self-devotion to the cause of liberty as the ancient Spaniards. They were trained from their infancy to martial deeds, and were early inspired with a love of liberty and a contempt of death—being taught to esteem nothing so glorious as to die fighting in defence of their country. Thus naturally brave, and capable of enduring great labour and fatigue, no reverses could shake their courage. They yielded only inch by inch to the whole power of the Roman empire. Armies, sufficiently numerous to conquer kingdoms, were slaughtered among their mountains; and their subjugation was completed only after a struggle of nearly 200 years. Spain, however, received in exchange for her independence wise laws and an equitable government; and soon became the richest, the happiest, and the most powerful province in the empire. Many Roman families of distinction settled in the country, and five and twenty colonies were distributed in the most fertile districts, who, intermarrying with the natives, consolidated the two nations as one people. The executive government was, in general, milder here than in any other of the Roman provinces. It was administered in towns by magistrates named by the citizens; and the different districts were under the superintendence of pretors or deputies, who had the charge of the public works, and the collection of the revenue. Many magnificent ruins, still existing, testify the opulence and civilization of Roman Spain; and several of her cities, as Merida, Seville, Cordova, and Tarragona, were numbered with the most illustrious of the world. During her long tranquillity agriculture and the arts were encouraged and protected by the emperors; her commerce was extensive and profitable; and her vegetable and mineral riches were improved and manufactured by the skill of an industrious and happy people. But as Spain had shared in the grandeur and civilization of Rome, she also participated in her decline. Under the last emperors, her population had considerably diminished, her commerce had become languid, and her agriculture had suffered by the accumulation of estates in the hands of a few. The peace and repose of four centuries had enfeebled the national character, and almost eradicated their love of glory: and the Spaniards, whom the Romans conquered, was as another race from those who submitted to the northern barbarians.

Chap. II. *Spain under the dominion of the Goths.*

The Suevi, Alani, and Vandals, in their progress southward, broke into Spain about the beginning of the fifth century; and, in a few years had reduced and partitioned among them that beautiful country. The native militia, for a time, successfully repelled the inroads of barbarians; but when these were supplanted by the mercenary guards, the gates of the Pyrenees were betrayed to the enemy, whose progress was marked by rapine and carnage. They exercised their cruelty indiscriminately upon the Romans and Spaniards; and ravaged with equal fury the cities and the open country. Famine, and its inseparable attendant, pestilence, swept away a large proportion of the inhabitants; and the barbarians were not satiated till they began to feel the destructive effects of those calamities which they themselves had occasioned. The majority of the nation submitted to the yoke of their conquerors; while a few maintained their independence in the mountains of Galicia. These barbarians, however, were not allowed long to enjoy their conquests. The Goths had become the allies of Rome by the marriage of their king with the daughter of the Emperor Theodosius; and were induced to draw their swords for the recovery of Spain. During three years the contest was obstinately supported with desperate valour and various success, when the superior achievements of the Gothic king at length prevailed, and Spain was once more restored to the authority of the empire. The Roman power was again overthrown by the Vandals; and after the passage of that people to Africa, the Suevi aspired to the conquest of the country, and threatened to extinguish the Roman dominion. But Theodoric the Goth, by one decisive victory, laid the foundation of the Gothic monarchy in Spain. Rechiarius, king of the Suevi, was taken prisoner and put to death, when the remains of his army retired to Galicia, and for more than a century his successors held a precarious authority in that province. Euric, the son of Theodoric, consolidated the Gothic power; and, in addition to his territories in Spain, his dominion extended from the Pyrenees to the Rhone. His son Alaric, however, was stript of his Gallic possessions by the victories of Clovis; but the Goths were amply compensated for their loss by the secure enjoyment of the provinces of Spain. They fixed the royal seat at Toledo; and the Suevic kingdom of Galicia was soon after added to the monarchy. The Romans, who had continued masters of the whole coast from the straits of Gibraltar to the confines of Valentia, and also held considerable possessions on the ocean, were confined within the small territory of Algarve, and this they held, by the moderation of the Gothic monarch, for nearly ten years, when king Suintilla became the first absolute master of the whole Peninsula.

The history of the Gothic dominion in this country, from the accession of Euric to that of Roderic, afford few materials of any interest. Their princes were frequently engaged in civil or religious wars; and long adhered to the wandering and warlike manners of their fathers. The dissolute and cruel reign of Witiza the predecessor of Roderic, had lost him the confidence and esteem of his subjects, and had occasioned a general defection throughout the kingdom. A civil war was the consequence, which ended only with the death or deposition of Witiza, and the accession of Roderic to the Spanish throne. The sons of the deposed monarch, however, could not brook their degradation from the rank of princes, and endeavoured to wrest the sceptre from the hands of their rival. They were still supported by a considerable party in the state; but unable to accomplish their object by their own strength, they began to intrigue with the Saracens, which paved the way for the speedy subjugation of their country by that ambitious people.

The followers of Mahomet had overrun the whole of Mauritania and reduced it to the obedience of their master, except the castle of Ceuta, which resisted for a time all their efforts. This fort, with a small district around it, was the only territory south of the straits belonging to Spain, and was entrusted to Count Julian, who defended it with such skill and intrepidity, that Musa, the Moslem commander, was compelled to retire with disgrace from before its walls. This nobleman, it is supposed, was married to a sister of king Witiza, and, being consequently involved in the downfall of the deposed family, his resentment was excited against the usurper of their rights. Besides his command in Africa, he possessed extensive estates and numerous followers in Andalusia, and thus held in his hands the keys of the Spanish monarchy. These, in an evil hour, he betrayed to the enemy; and this Christian commander, who had so nobly repulsed that very enemy from the gates of Cueta, forgetting the highest claims of religion and of country, sacrificed all in revenge of a private wrong. When the first intimation of his purpose was conveyed to Musa, the wily Moslem hesitated to trust an army of the faithful to the traitors of a foreign land: but having ascertained what might be expected from the intrigues and influence of the count, and having been well informed of the dissensions among the Spaniards, he despatched an army under Tarik to the easy conquest of a populous and wealthy kingdom. On the descent of the Saracens, Roderic hastily collected a small army to oppose their progress, and to check the devastations which they committed upon the unarmed inhabitants. He, at the same time, endeavoured to heal the divisons which were so fatal to his country, and was so far successful that the sons of Witiza, with a seeming devotion to the common cause, joined his standard with their dependants. The bishops also, and the flower of the nobility assembled with their followers at the royal summons; and his army amounted to nearly one hundred thousand men; but they were without discipline, and their fidelity was suspected. The troops of Tarik were composed of twelve thousand veteran Saracens, and a crowd of Moors who were eager to share in the expected plunder. The two armies met on the plain of Xeres, and after three days of hard skirmishing they joined in a general engagement. The issue was long doubtful. Sixteen thousand Moslems had fallen under the swords of the Goths; and they would soon have been overwhelmed by the numbers of the Christians, had they not been saved by the defection of the sons and brother of Witiza, who held the most important post in the army of Roderic. The ranks of the Christians being thus broken and thrown into disorder, opened a way for the action of the Moorish cavalry, which made prodigious havock; and during the three succeeding days of flight and pursuit, the remains of the Gothic army were scattered or destroyed. This decisive and fatal battle sealed the ruin of the Gothic monarchy in Spain: and in the course of a few years, the victorious Moslems had subjected the finest provinces of the peninsula to the obedience of the caliph. The vanquished were allowed to retain their laws, religion, and language, upon the payment of an annual tribute; but many who preferred a life of poverty with the unrestrained exercise of their religion, to the precarious possession of their properties, retired under Pelagius, a prince of the blood, into the mountains of Asturias, where, forgetting every other care, sought only to provide for their safety and freedom. Here the vital spark of national independence was cherished and kept alive; and it was thence that the successors of these warriors emerged in after times, and by degrees recovered their country from the Moorish yoke.

Remarks. During this period, Spain presents to us a compact monarchy, concentrated within its natural limits, whose laws, manners, and religion, have in a great measure remained unaltered for fourteen centuries. The crown was elective in a council of bishops and nobility, styled *palatines*, who, while they swore allegiance, bound the monarch by a reciprocal oath that he would execute faithfully his important trust. The only indispensable requisite in the king was his being descended from the illustrious blood of the Goths. But though he derived his title from election, his power was almost absolute. He had the sole command of the army, bestowed all places of trust and profit, assembled and dissolved the national councils, exercised an ecclesiastical supremacy, and further had the power of making laws, which were revised, confirmed, and published by the assemblies of the states.

The administration of justice was strictly exercised throughout the kingdom, and the greatest reverence was everywhere paid to the laws. Before the reign of Euric, the Goths had no written jurisprudence; but this prince employed some of the most learned and eminent men in the kingdom in composing a body of laws, called the Theodorictan code, which he imposed upon all his subjects both in Gaul and in Spain. His successor Alaric, however, abrogated these, and restored the Roman laws, which continued in use until a new code of civil and criminal jurisprudence was examined and ratified by a legislative council at Toledo. This code contained the edicts of a succession of kings from Euric to Ejica, and, uniting a part of the Roman law with the Christian morality, formed a body of laws superior to all others then in existence. The native Spaniards, who were long separated from the Goths by the irreconcilable difference of religion, were at length raised to a participation of the same privileges with their conquerors; and all insensibly submitted to the restraint of an equitable rule.

The Goths, on their first entrance into Spain, were Arians; and for more than a century continued devotedly attached to that persuasion, till the conversion of king Recared, who, with the principal nobility, publicly renounced the errors of Arius, and embraced the catholic faith. The Spanish church at this time, though oppressed and persecuted, had retained much of its primitive purity; and even after its doctrines became the established faith of the kingdom, it still maintained its integrity and respectability. It was in a great measure free from those gross superstitions which then prevailed in the church of Rome. The Roman pontiffs were never able to obtain any right of interference in its concerns; and in one of the last councils held at Toledo, his claims of jurisdiction in Spain were rejected with contempt, and treated as an usurpation. The pious and temperate lives of its bishops were often conducive to the order and stability of the state, and the influence of the clergy in general was uniformly directed to the support of the best interests of the king and the people. It was indeed greatly owing to the predominance of episcopal policy in the national councils that the Gothic dominion in Spain was rendered friendly to the vanquished at home, and formidable to its foreign enemies, maintaining the authority and vigour of the laws, securing the privileges of every class of the community, and protecting all in the enjoyment of their property.

In the earlier ages of the Gothic rule in this country, industry and the useful arts were greatly neglected; and the warlike barbarians regarded with indifference all those accomplishments which can only be appreciated in a more refined and civilized state of society. But during a long peace, and a succession of wise administrations, agriculture and commerce had rapidly advanced, and had introduced a state of prosperity and refinement, which corrupted both prince and people. The favourite exercise of arms had been long abandoned by the Spanish youth. The floodgates of luxury were opened, and a love of ease and pleasure pervaded all ranks. The walls of their cities were mouldering into dust; and the descendants of those hardy bands who had humbled the pride of Rome were slumbering in security, ready to become a prey to the first invaders.

Chap. III. *Spain in subjection to the Moors.*

The first Moorish invaders under Tarik, consisting of various tribes, asserted, by assuming the name of Spaniards, their original claim of conquest; and though they were afterwards joined by numerous bands of Arabs of different countries, who were allowed to share in the fruits of this important enterprise, they appropriated to themselves the most fertile districts of the country. "The royal legion of Damascus was planted at Cordova; that of Emesa at Seville; that of Kinnisrin or Calchis at Jaen; and that of Palestine at Algezire and Medina Sidonia. The natives of Yemen and Persia were scattered around Toledo and the inland country; those of Egypt were established at Murcia and Lisbon; and the fertile seats of Granada were bestowed on the ten thousand horsemen of Syria and Irak, the children of the purest and most noble of the Arabian tribes." A spirit of emulation and jealousy existed among these different tribes, which gave rise to frequent disputes, and which, being nourished by a factious and hereditary pride, scattered those seeds of division, which afterwards ripened into a full harvest of intestine broils, and which led to their final expulsion from the peninsula.

The Moorish conquests in Spain continued to be governed by a lieutenant of the Caliph of Damascus until the deposition and destruction of the Ommiades in Arabia, when Abdalrahman, a royal youth, who alone had escaped the massacre of his house, fled into Spain, where he was hailed with joy by the party attached to his family. After a short and successful struggle with the lieutenant and forces of the rival family of the Abbassides, he established the throne of Cordova, and became the first Caliph of the west. The dynasty of the Ommiades continued to reign in this country with great splendour for nearly two centuries and a half, when the Spanish Caliphate expired. Their dominions were split into several petty states by the rebellion of the Moorish governors, who usurped the sovereignty of the provinces over which they presided, and assumed the royal style in Cordova, Seville, Valentia, and Granada. This dismemberment occasioned constant wars, which were sometimes prosecuted with all the rancour of hereditary feuds; and during which the monarchs, as well as the boundaries of the different kingdoms, were continually changing. Their limits were also greatly circumscribed by the conquests of the Christians, who were gradually extending their territories, and threatened the complete recovery of their native possessions.

The Goths, who had retired with Pelagius to the mountains of Asturias, had chosen that prince as their monarch: and his territories were at first confined to the small province of Liebana with the hamlet of Cangas for its capital. This district was so fortified by nature, that, with a few defenders, it was capable of resisting almost any number of invaders. Here Pelagius laid the foundation of the kingdom of Leon, and of the Spanish monarchy; and defied the whole power of the Moors, who twice attempted with numerous armies to dislodge his little band of patriots; but were as often overthrown with dreadful slaughter. By these victories he became master of all the Asturias, and soon after extended his dominion over the best part of Biscay. His little territory afforded an asylum to the oppressed Christians, who, retiring privately from the Moorish provinces, repaired in great numbers to his standard, and by thus recruiting his forces, enabled him and his immediate successors, to descend with more confidence into the lower and more fertile parts of the country, and to push their conquests, on the one hand, as far as Castile; and, on the other, to the confines of Portugal. The kingdom of Leon increased rapidly in extent and resources during the reigns of Alphonso III, who subdued Galicia, and spread his dominion as far as Coimbra, and of Ramirus II, who penetrated to Madrid, which he took by storm, and even threatened Toledo, at that time one of the strongest cities in the hands of the Moors. Encouraged by the successes of the Christians in Leon, other provinces began to establish themselves as independent states, and by similar means, rose to power and distinction. The independence of Navarre commenced about the middle of the ninth century; that of Castile thirty years later; and Aragon was erected into a kingdom in the beginning of the eleventh century. The wars and events which led to the formation of these kingdoms, were signalized by many heroic achievements; and no history records a succession of kings so remarkable as those who shone in those different states. Several of the name of Alphonso were distinguished and able princes, one of whom invented the Alphonsine tables, and superintended the digesting of a code of laws, which likewise bears his name. By the establishment of these states the Moors were driven from the finest provinces of the Peninsula, and confined within the kingdom of Granada. In a series of years, however, by the usual events of intermarriages, or succession, or conquest, all these were united under Ferdinand and Isabella, the former the hereditary monarch of Aragon, and the latter, the heiress of Castile and Leon.

As our limits will not admit of any detail of these transactions, we shall content ourselves with presenting here a chronological table of the different kingdoms, with the periods of their formation, and the sovereigns by whom they were governed.

Leon and Asturias.	Barcelona Counts.	Navarre.	Castile.	Aragon.
718. Pelagius.	801. Bera.	831. Aznar, Count.	1035. Ferdinand I.	1035. Ramirus I.
737. Favila.	820. Bernard.	836. Sancho.	In 1037, the kings of Castile became kings of Leon and Asturias.	1070. Sancho I.
739. Alphonso I. the Catholic.	844. Alderan.	853. Garcias.	1065. Alphonso VI. and I. of Castile	1094. Peter I.
757. Froila I.	858. Wifred.	857. Garcias-Ximenes.	1070. Sancho II.	1104. Alphonso I.
768. Aurelio.	872. Salamon.	880. Fortunio I. the first king.	1072. Alphonso VII.	1134. Ramirus II.
774. Silo	880. Wifred II. the Warlike.	905. Sancho I.	1109. Urraca and Alphonso VIII.	1137. Pelonille and Raymond-Berenger.
783. Mauregat, an usurper.	911. Miran.	926. Garcias I.	1157. Sancho III.	1162. Raymond, surnamed Alphonso II.
788. Bermudus I.	928. Seniofred.	978. Sancho II.	1158. Ferdinand II.	1196. Peter II.
791. Alphonso II. the Chaste.	967. Borellus.	994. Garcias II.	1188. Alphonso IX.	1213. James the Victorious.
842. Ramirus I.	993. Raymond I.	1000. Sancho III. the Great.	1214. Henry I.	1276. Peter III. deposed.
850. Ordogno I.	1017. Berenger I.	1035. Garcias III.	1217. Ferdinand III.	1285. Alphonso III.
886. Alphonso III. the Great.	1035. Raymond II.	1054. Sancho IV.	1252. Alphonso X. the Wise.	1291. James II.
911. Garcias.	1067. Raymond III.	1076. Sancho V.	1284. Sancho IV.	1327. Alphonso IV.
914. Ordogno II.	1081. Raymond-Berenger IV.	1094. Peter I.	1295. Ferdinand IV.	1336. Peter IV.
923. Froila II.	1131. Raymond-Berenger V. who died in 1162, when the county of Barcelona passed to the king of Aragon.	1104. Alphonso.	1312. Alphonso XI.	1387. John I.
924. Alphonso IV.		1134. Garcias IV.	1350. Peter the Cruel.	1395. Martin.
927. Ramirus II.		1150. Sancho VI.	1369. Henry II.	Interregnum.
950. Ordogno III.		1194. Sancho VII.	1379. John I.	1412. Ferdinand.
955. Ordonio, an usurper.		1234. Thibaut I.	1390. Henry III.	1416. Alphonso V.
955. Sancho the Big.		1253. Thibaut II.	1406. John II.	1458. John II.
967. Ramirus III.		1270. Henry.	1454. Henry IV.	1479. Ferdinand II. married Isabella of Castile.
982. Bermudus II.		1274. Joanna I. and Philip, king of France.	1474. Isabella and Ferdinand V. king of Aragon.	1516. Charles I. who inherited from his mother Joanna the monarchy of Spain
999. Alphonso V.		1305. Louis Hutin, king of France. Interregnum.	1504. Joanna and Philip.	
1027. Bermudus III.		1316. John I.		
		1316. Philip the Long, king of France.		
		1322. Charles, king of France.		
		1328. Joanna II.		
		1349. Charles II. the Bad.		
		1387. Charles III.		
		1424. John II.		
		1479. Eleonora.		
		1479. Gaston-Phœbus of Foix.		
		1481. Interregnum.		
		1483. Catherine. John d'Albert.		
		It became subject to Castile in 1512		

The first care of Ferdinand and Isabella, after having wisely settled the interior affairs of their dominions, was the recovery of Granada. An opportunity was soon found for breaking the peace with the Moors; and after a protracted and bloody war, this wealthy kingdom, which had occupied a large proportion of the south of the Peninsula, having under its jurisdiction thirty-two cities and ninety-seven walled towns, was reduced within the small compass of the city of Granada. Being now invested by the Spaniards, and all communication with the surrounding country cut off, the inhabitants were reduced to the utmost extremity. The Moors, however, made a gallant defence; and received an honourable capitulation, in which it was stipulated that the inhabitants should retain the undisturbed possession of their property, the use of their laws, and the free exercise of their religion. Thus this last strong-hold of the Arabs in Spain submitted to the Christian arms, after an almost uninterrupted war of eight centuries, and during which, according to the Spanish historians, three thousand seven hundred battles were fought. Shortly after the battle of Xeres in 712, the Moors had overrun the whole Peninsula, except a small district in the mountains of the Asturias; but the tide of victory was not long in setting in from an opposite direction; and they were gradually driven by the arms of the Christians from all their possessions in Spain: from the Asturias in 716; from Salvarba in 750; from Catalonia in 820; from Leon in 923; from Castile in 1073; from Aragon 1118; from Cordova and Jaen in 1236; from Seville in 1248; from Valentia in 1264; from Murcia 1265; and from Granada in 1492.

The important conquest of Granada was, in the same year, followed by the more important discovery of America by Christopher Columbus; which, with its subsequent conquest, redounded more to the glory and fame of Isabella than any other act of her reign; and as she consented to defray the whole expense of the expedition, without the concurrence of Ferdinand, she reserved for her subjects of Castile exclusively all the advantages resulting from such an undertaking.

Upon the death of Isabella, the archduke Philip, king of the Netherlands, who had married her daughter Joanna, a princess of very slender capacity, claimed the crown of Castile in right of his wife. Ferdinand, who, by the will of his queen, had been appointed regent of the kingdom till her grandson Don Carlos should attain the age of twenty, found it prudent to resign the regency and retire to his own dominions of Aragon. The reign of Philip, however, was short and turbulent. He disgusted the nobility by his great partiality to his Flemish favourites, upon whom he bestowed all places of trust and emolument; and also by his cruelty to his queen, whom he wished to deprive of the government, and to confine as a deranged person. This conduct spread universal discontent, the consequences of which were averted only by his death, which happened about seven months after his arrival in Spain. The affairs of Castile were thus thrown into great confusion, and the states, in order to maintain the tranquillity of the kingdom, invited Ferdinand to resume the regency, which he held until his death in 1515.

This monarch was one of the greatest princes that ever ruled in Spain, and possessed in a very high degree the love and affection of his people, who lamented his loss with unfeigned sorrow; and called him with great justice, their father and deliverer. He bequeathed his hereditary dominions, and also the kingdoms of Naples and Navarre, which he obtained by conquest, to Joanna queen of Castile, and after her to his grandson Don Carlos. He appointed Cardinal Ximenes, archbishop of Toledo, regent of Castile; and bestowed the regency of Aragon and its dependencies upon his natural son Don Alonzo, archbishop of Saragossa.

Remarks.—It could scarcely have been expected that during this period, when the Peninsula was divided into small kingdoms without frontiers and guaranty; and governed by sovereigns of different nations and religions, who were almost continually at war with each other, much attention would be devoted to its agricultural and commercial interests. Yet that portion of it which was subject to the Moors, enjoyed a degree of prosperity and civilization, unexampled in Spain during any other period of its history. This people were particularly skilled in agriculture, and carried every branch of public and private economy to a high degree of perfection. They paid the most minute attention to the analysis, classification, and manure of the different soils, to rustic buildings, plantations, and agricultural implements, and to the care of animals. They divided their lands into small fields, which were kept constantly under tillage, and by their reservoirs and canals, they conveyed water to the highest and driest spots. They were the first who introduced into this country the cultivation of rice, sugar, cotton, and silk; and the general appearance of their estates formed a striking contrast to the domains of the crown, and the immense wastes of the Gothic lords. They were also expert in all the mechanical arts; and in almost every city were established looms, forges, mills, glass-houses, &c. The invention of paper is due to this people; and many kinds of manufactures, particularly silk and cotton stuffs, morocco leather, &c. were brought by them to so great perfection, that, in the twelfth century, the tissues of Granada and Andalusia were highly prized at Constantinople and throughout the Eastern empire. Their skill in architecture was equally conspicuous; and the *Alhambra* of Granada, still in existence, is an evidence of the fine taste, studied elegance, and ability of their artists. To this improved state of industry the Moors added the love of science and learning. These they introduced into Europe at a time when it was immersed in darkness; and they possessed many luxuries unknown to the neighbouring nations. "The successers of Abdalrahman had formed a library of 600,000 volumes, 44 of which were employed in the mere catalogue. Their capital of Cordova, with the adjacent towns of Malaga, Almeria, and Murcia, had given birth to more than 300 writers; and above 70 public libraries were opened in the cities of the Andalusian kingdom." The Arab historians describe the reign of the Ommiades as the most splendid and prosperous era of Moorish Spain. "The third of the Abdalrahmans derived from this kingdom the annual tribute of 12,045,000 dinars or pieces of gold, about six millions Sterling, his royal seat at Cordova contained 640 mosques, 900 baths, 200,000 houses; he gave laws to 80 cities of the first, to 300 of the second and third order; and the fertile banks of the Guadalquivir were adorned with 12,000 villages and hamlets, The inmates of his seraglio, comprehending his wives, concubines, and black eunuchs, amounted to 6300 persons; and he was attended to the field by a guard of 12,000 horse, whose belts and scimitars were studded with gold." To this extraordinary concurrence of industry, wealth, talents, and learning, this people united that romantic gallantry which so eminently prevailed in the ages of chivalry; and their noble conduct in many instances, inspired with confidence in their honour, even the enemies of their kingdom and of their faith.

This high state of prosperity and refinement, however, was confined chiefly to the Moorish dominions. The descendants of the Goths were entirely occupied in the pursuit of independence and military glory. They were forward to imitate, and often surpassed their rivals in the noble qualities of generosity and honour, and in all those deeds which spring from a romantic and chivalrous spirit, but they disdained to follow them in the pursuits of industry and science. Preferring the wandering and martial life of their fathers, they never could be induced to relinquish their ancient habits and manners for the advantages of agriculture and the mechanical arts. The care of flocks and herds, which from time immemorial had enriched the kingdoms of Castile and Leon, appeared to them a securer source of wealth, and as they were involved in continual wars, was more easily removed from the inroads of an enemy. In those times all the inhabitants capable of bearing arms followed the standard of their lords. Their flocks and herds were entrusted to the care of the old men, women and children, who were totally unfit for the laborious duties of an extended agriculture; and as the quantity of corn which they raised was insufficient for their consumption, they were under the necessity of exchanging their wool, hides, iron, and oil, for the grain and manufactures of their neighbours. Their aversion to rural employments and the arts was thus the consequence of their situation and the circumstances in which they were placed; and during peace the enthusiasm of war and chivalry degenerated into a spirit of pride and of idleness incompatible with an industrious application to mechanical labour. This spirit was almost universal among the Spaniards, except in the Moorish cities, where the Christians by their constant intercourse with them, had learned their arts and continued to cultivate them. While the Moors, though a vanquished people, continued in the peninsula, the country was greatly benefited by their industry and their genius; but after the expulsion of a great proportion of them, in consequence of frequent revolts, Spain was never able to supply the demands of her inhabitants, and so became a constant tributary to the industry of other nations. The establishment of the inquisition by Ferdinand and Isabella also tended in no small degree to deprive this country of its most industrious population. The Jews who, after the Moors, had engrossed almost all the wealth and commerce of Spain, were so exposed to its merciless rage, that they were compelled to leave the kingdom or to embrace Christianity; and it is calculated, that within four years after the appointment of Torquemada, the first inquisitor-general, 6000 persons, chiefly of this unfortunate race, were burned by order of this sanguinary tribunal, and that upwards of 100,000 felt its fury.

With respect to the political institutions of the Gothic Spaniards during this period, they still adhered to their ancient laws, not only from attachment to them, but out of antipathy to the Moors, who held very different notions concerning property and government. These, however, were considerably changed by a variety of concurring causes. As the different kingdoms were wrested from the Moors gradually and with difficulty, the nobles who followed the standard of their chief conquered not for him alone, but for themselves. "They claimed a share in the lands which their valour had won from the enemy; and their prosperity and power increased in proportion as the territory of the prince extended." The sovereign being thus obliged to conciliate their good will by successive grants of new honours and privileges, before he could establish his dominion in a conquered province, the greater part of the territory was parcelled out by him among his barons, with such jurisdictions and immunities as raised them almost to sovereign powers. The monarch was thus but a little elevated above his nobles; and they, feeling their independence, often acted as his equals. The cities of Spain had also obtained very considerable power during this struggle. As the open country was perpetually exposed to the depredations of the enemy, with whom no peace or truce was permanent, persons of all ranks were obliged, for self preservation, to fix their residence in the cities. These at length became the only places of safety; and as many of them were, during a longer or shorter period, the capitals of little states, they enjoyed all the advantages which accelerate the increase of inhabitants in every place which is the seat of government. Their number at the beginning of the fifteenth century was very considerable, and were peopled far beyond the proportion which was common in other parts of Europe; and as their assistance was frequently required in prosecuting the war against the Moors, their monarchs found it necessary to gain their favour by ample concessions, which not only extended their immunities, but added to their wealth and power. By the exorbitant privileges of the nobility, and the unusual power of the cities, the royal prerogative was hemmed in on every side, and reduced within very narrow limits, and when the Castilian nobles combined against Henry IV. they arrogated, as one of the privileges belonging to their order, the right of trying and passing sentence upon their sovereign, which they carried into effect by deposing him from the throne. Several monarchs, impatient of such restraint, endeavoured at various junctures, and by different means, to enlarge their authority, but it was left for Ferdinand to accomplish in some degree the extension of the sovereign's prerogative, which his predecessors had so long and so frequently attempted in vain.

Owing to the restricted power of the monarch and the feebleness of the government, the different Spanish states presented, during the greater part of this period, a scene of the utmost disorder and insubordination. The bonds of civil society seemed to have been burst asunder. The administration of the laws was so extremely weak, that it afforded no protection to the subject; and robbery and murder became so common, as not only to intercept the internal commerce of the kingdom, but in a great measure to suspend all intercourse between its cities. The feudal barons who were sufficiently forward to assist their prince in repelling foreign aggressions, or in extending his dominions, were equally ready in resisting any encroachments upon their privileges, which were alike inimical to the stability of the throne and the welfare of the people. They claimed and exercised a sovereign jurisdiction within their own territories; and this, with their frequent private wars, the want of discipline among the troops, and the incessant depredations of the infidels, filled the provinces of Spain with confusion and tumult. The inhabitants of the cities were the greatest sufferers; and as a measure of self defence, the cities of the kingdom of Aragon, and after their example those of Castile, formed themselves into an association, distinguished by the name of the *Hermandad*, or "Holy Brotherhood." They exacted a certain contribution from each of the associated towns; they levied a considerable body of troops, in order to protect travellers and to pursue criminals; they appointed judges, who opened their courts in various parts of the kingdom. Whoever was guilty of murder or robbery, or of any act that violated the public peace, and was seized by the troops of the Brotherhood, was carried before judges of their nomination, who without paying any regard to the exclusive and sovereign jurisdiction which the lord of the place might claim, tried and condemned the criminals. By the establishment of this fraternity, the prompt and impartial administration of justice was restored; and together with it internal tranquillity and order began to return. The nobles alone murmured at this salutary institution. They complained of it as an encroachment on one of their most valuable privileges. They remonstrated against it in a high tone: and, on some occasions, refused to grant any aid to the crown unless it were abolished." Ferdinand, however, was too sensible of the good effects of such an institution to listen to any proposal for abridging its powers. He supported it on all occasions with the whole force of royal authority; for to limit and abolish the independent jurisdiction of the nobility was one of the great objects of his policy; and this he in a great measure accomplished by his perseverance and the assistance of the Hermandad. When the deputies from the states of Aragon, who had refused him supplies in his war with France, offered to accede to his demands upon condition of his restoring the territorial jurisdiction, he ordered them from his presence, declaring that "he would not purchase a supply at the expense of the liberties of his subjects; that before his reign the vassals of the nobility were their slaves; that he had made them free, and would keep them so." Notwithstanding, however, the exertions of this able and wise prince, the spirit of liberty was so vigorous among the people, and the spirit of independence so high among the nobility, that the kingly prerogative was less extensive in Spain than in any other of the great monarchies of Europe.

Chap. IV. *Spain while under the dominion of the Austrian dynasty.*

The affairs of Spain, until the arrival of Charles, were conducted by the aged Cardinal Ximenes with such wisdom, integrity, and firmness, that the kingdom felt not the loss of the powerful mind of Ferdinand. Many of the nobles who, supposing that the reins of government would be relaxed under the delegated power of a regent, had taken up arms to prosecute their private quarrels and pretensions, were compelled to repress their hostilities and to submit to the terms of the Cardinal. The decision and vigour of his administration, and the high authority which he assumed, excited the fears of the nobility for the safety of their peculiar privileges; and when they sent a deputation to question his power, and demand by what right he held the regency of the kingdom, he showed them the will of Ferdinand, ratified by Charles. This, however, not seeming to produce the acquiescence which he wished, he led them to a balcony, and pointing to a body of troops and a train of artillery stationed before the palace, said, "These are the powers by which I mean to govern Spain until the arrival of his majesty." But the exertions of this able minister, who, during his short regency, did so much for the security of the kingdom, and the extension of the royal prerogative, were rewarded with neglect and disgrace. On the arrival of Charles at St. Andero, Ximenes hastened to meet him, but was seized during the journey with a violent disorder, supposed to be the effects of poison. This accident obliged him to stop at Aranda, from whence he wrote to the king, earnestly desiring an interview, and at the same time advising him to dismiss all the strangers in his train, whose numbers and influence already gave great offence to the Spaniards, and who would ere long alienate the affections of the whole people. This advice was disregarded; and the Flemish courtiers, jealous of the power of the Cardinal, industriously kept the king at a distance from Aranda, and at length prevailed with him to dismiss this faithful minister and supporter of his throne. Ximenes died a few hours after receiving this communication, leaving behind him a reputation for wisdom and sanctity, prudence and boldness, which no monarch or minister had ever enjoyed in that country.

After the death of Ximenes, Charles found great difficulty in establishing his authority in Spain. His Flemish favourites, by their exactions and avarice, had become odious throughout the kingdom; and several cities of the first rank in Castile entered into a confederacy for the maintenance of their rights and privileges. This confederacy assumed the name of the Holy Junta, and bound themselves by a solemn oath to live and die in the service of the king, and in defence of the privileges of their order. As Charles was now absent in Flanders, they appointed a deputation to wait upon his majesty, and drew up a remonstrance, which contained not only an enumeration of their grievances, but also many new regulations for the security of their liberties; and which show that the Spaniards of that day had acquired more liberal ideas, with respect to their own rights and privileges, and had formed more bold and generous sentiments concerning government, than other people in Europe. The nobles, while they supposed that the demands of the Junta were confined to the redress of such grievances as had arisen from the inexperience of the monarch, or the rapacity of his courtiers, connived at, and even favoured their proceedings: but when they perceived that their own peculiar privileges were in some danger, they immediately joined the forces of the regent. After a contest of nearly eight months, which was prosecuted with a rage and fury peculiar to civil insurrections, and which was attended with many fruitless negotiations the army of the Junta, under Don Juan Padilla, was completely routed near Villelar, when three of their chiefs were taken prisoners, and immediately executed. After this defeat, the city of Toleda alone maintained the struggle, being animated by the presence and courage of Donna Maria Pacheco, Padilla's widow, a woman of rank, abilities, and boundless ambition. When driven to the citadel, she defended it for four months with amazing fortitude; but being at last reduced to great extremities, she made her escape into Portugal. Similar troubles prevailed in Valencia, where the commons assumed the name of *Germanada*, and also in Aragon and Majorca; but the spirit of disaffection was completely crushed before the arival of the king in 1522.

Charles, who had now obtained the imperial crown, proceeded with great prudence and moderation to heal the unhappy divisions which had distracted Spain during his absence. He proclaimed a general pardon for all crimes committed during the insurrection, with the exception of about eighty persons, of whom, however, very few suffered; and many who were of rank had their outlawry reversed, and were restored to their honours and estates. This act of clemency was condemned by his council, who strongly solicited him to make some more examples; but he answered that "enough of blood had been already shed;" and when one of his courtiers, in expectation of a reward, officiously informed him where one of the proscribed party was concealed, he sharply replied, "You had done better in advising Ferdinand de Avalos to be gone, than in putting me in the way to apprehend him." By this magnanimous conduct, and by "his address in assuming the manners, and speaking the language of the Castilians, he acquired an ascendency over the people which hardly any of their native princes had ever attained, and brought them to support him in all his enterprises, with a zeal and valour to which he owed much of his success and grandeur."

It would be foreign to our purpose to follow this prince in his campaigns in the Milanese, and his wars with France, which continued with little interruption during the whole of his reign. These belong more properly to his history as Emperor of Germany, and a succinct account of which will be found in the article FRANCE. Spain was but as one of the provinces of his extensive dominions; and however much his successes in these wars might redound to his own glory, and throw a gleam of splendour around his name as a warrior and a politician, they were fatal to the internal improvement of this kingdom. The produce of its soil, the treasures of its colonies, and the flower of its population, were dissipated in foreign lands in the prosecution of his ambitious schemes. His demands for subsidies were repeatedly refused by the cortes; and his impoverished subjects were frequently upon the eve of a rebellion, which was prevented only by his foresight and prudence.

After the treaty of Cambray in 1529, which gave a short repose to Europe, Charles meditated an expedition against the piratical states of Africa. The famed Horne Barbarossa, who from a private corsair had raised himself by his singular valour and address to be king of Algiers and Tunis, had become terrible by his depredations from the Straits of the Dardanelles to the rock of Gibraltar. Daily complaints were made to the emperor by his subjects, both in Italy and Spain; and all Christendom seemed to look to him for deliverance from this new and odious species of oppression. For this enterprise, which was very popular among all classes, he obtained abundant supplies; and having embarked with the flower of the Spanish nobility for Cagliari, which was the general place of rendezvous, he from thence sailed for Tunis with a fleet of 500 sail, having on board 30,000 regular troops. Barbarossa was prepared for the attack. He had strongly fortified the fortress of Goletta, which is situated on a neck of land, and commands the bay of Tunis, and in the strength of which he placed his chief confidence. Charles on his landing laid siege to this fortress, and after a month of daily skirmishing, took it by storm on the 25th of July 1535, when the whole piratical fleet fell into his hands. He then proceeded to Tunis, but was met upon the march by the army of Barbarossa, which he completely routed, when his troops, flushed with victory, and eager for plunder, rushed into the city, and, in spite of all his exertions to restrain them, committed every species of excess and cruelty. Thirty thousand innocent inhabitants perished on that occasion, and ten thousand were carried away as slaves. Having restored Muley Hassan, the former monarch, and bound him by treaty to hold the kingdom of Tunis as a vassal of the crown of Spain, he garrisoned the Goletta with Spanish troops, and returned to Europe.

The expedition of Charles against Algiers, however, about six years afterwards, was not so fortunate. He disembarked his army on the coast of Africa at too advanced a season of the year; and before the provisions and warlike stores could be landed, his fleet was dispersed by a tempest, in which 15 ships of war, and 140 transports, with 8000 men perished. Such of his vessels as had escaped, received his dispirited troops, but being overtaken by another storm, the emperor with difficulty reached Carthagena, extremely mortified at the failure of his favourite scheme.

On his return, Charles found himself embroiled in new wars. Having committed the government of Spain to his son Don Philip, who, as heir apparent, had received the oath of fidelity from the cortes, he passed over to Flanders, and the remainder of his reign was spent in his contest with France and the protestants of Germany. At the same time, however, that he was prosecuting his plans of conquest and of aggrandizement on the continent, he formed the ambitious project of adding England to the dominions of his family. He succeeded in accomplishing a treaty of marriage between his son and Mary of England, by which it was stipulated that their heirs should, together with the crown of England, inherit the duchy of Burgundy and the Netherlands; and if Don Carlos, Philip's son by a former marriage, should die without issue, they should succeed also to the crown of Spain, with the emperor's hereditary dominions.

Worn out at length by his arduous duties and the ravages of the gout, and conscious of his inability much longer to direct with vigour the multiplicity of affairs which called for his attention throughout his extensive dominions, he resolved to resign his hereditary states to his son Philip, who had now attained his 28th year, and having been early accustomed to business, had discovered both inclination and capacity sufficient to sustain the weighty burden which was about to devolve upon him. For this purpose he recalled Philip from England, and having assembled the states of the low countries and of Brussels, Charles seated on a chair of state, and surrounded by a splendid retinue of the princes of the empire and grandees of Spain, with great solemnity surrendered to his son all his territories, jurisdiction, and authority in the low countries. A few weeks afterwards, he resigned with great solemnity, and in an assembly no less splendid, the crown of Spain, "reserving, of all his vast possessions, nothing for himself but an annual pension of one hundred thousand crowns to defray the charges of his family, and to afford him a small sum for acts of beneficence and charity." In the following year he returned to Spain, and retired to the monastery of St. Justus, near Placentia. Here in a mean retreat, he forgot the ambitious thoughts and projects which had so long engrossed his mind, and which for half a century, had filled with terror all the kingdoms of Europe, and devoting the evening of life to innocent amusements and religious exercises, died on the 21st of September 1558.

Philip II., though his father, with all his power and influence, was unable to obtain for him the imperial crown, succeeded to a sceptre more powerful perhaps than that of any monarch of the age. Besides his dominions in Europe, including Spain, Naples, the duchy of Milan, and the Netherlands, he possessed in the new world territories of such vast extent, abounding in inexhaustible veins of wealth, and opening such boundless prospects of every kind, as must have roused into action a mind much less ambitious and enterprising than that of Philip. He inherited with his crown a war with France and the pope, but this was but of short duration; and the treaty of Chateau Cambresis left him without an enemy. In memory of the battle of St. Quintin, fought in this war, "on the day consecrated to St. Laurence, he built the splendid and magnificent palace of the Escurial, in honour of that saint and martyr, and so formed the plan of the work as to resemble a gridiron, which, according to the legendary tale, had been the instrument of St. Laurence's martyrdom." This prince, however, was not of a disposition to remain long inactive; and though he was not desirous of military glory, yet in other respects, he was not inferior to his father either in ambition or abilities; and during a long reign, he gave more disturbance to his enemies by his political intrigues, than the emperor had ever done by his arms.

The severity of Charles's government in the Netherlands, with respect to religious matters, had estranged from him the affections of his subjects in that country; and the violent and bigoted principles of Philip's administration, under the Duke of Alva, exasperated them into open rebellion. This afforded employment to the arms of Spain for nearly half a century, and at last lost to that crown one half of its most valuable possessions in the low countries. (See Netherlands.)

The same spirit of intolerance which raised such a flame in the Netherlands, stirred up the Moors in Spain to a similar resistance. This industrious people, since their subjection, had lived as quiet subjects. But it had been insinuated to the court of Rome, that though nominally Christians, they still adhered to the Mahometan faith, which induced the pope to press upon Philip the necessity of bringing them by force within the pale of the Catholic church. The king ever ready to listen to the instigations of monkish zeal, sent express orders into the kingdom of Granada, to oblige the Moors to change at once their habits, manners, and language; and the clergy were enjoined to require the registration of all Moorish children between five and fifteen years of age, that they might be taught the Castilian tongue, and be instructed in the Catholic faith. Notwithstanding the humble representations of loyalty and attachment from this unfortunate race, and the louder remonstrances of the governor and principal officers of the province, against so impolitic and impracticable a measure, Philip remained inflexible. The Moors were driven to despair, and having taken up arms, renounced their allegiance to the king of Spain, and proclaimed one of their chiefs king of Granada and Cordova. The struggle was prosecuted on the part of the Moors with all the fury of religious frenzy, committing every where the most outrageous excesses, and inflicting inexcusable cruelties upon the innocent inhabitants, particularly ecclesiastics: while the Spanish commanders acted with great moderation, treating their prisoners with lenity, and receiving many to mercy. This war lasted between two and three years, cost the lives of 20,000 Castilian soldiers, of about 100,000 Moors, and depopulated and destroyed some of the finest countries in Spain.

About this time was formed what is called the Holy League against the Turks, and in favour of the Venetians, one half of the expense of which was to be defrayed by the king of Spain. The command of the armament, consisting of 200 gallies, with 50,000 foot, and 4000 horse, was given to Don John of Austria, the king's half-brother, who obtained a signal victory over the Ottoman fleet, in which 30,000 Turks were killed, 10,000 taken prisoners, and 15,000 Christian slaves set at liberty. But the fruits of this victory were lost from want of unanimity among the leaders of the league: and from the same cause, in the following year, another Turkish fleet was saved from destruction. The consequence of this was, that the Turks made a descent upon the coast of Africa, reduced Tunis and the Goletta, which the Spaniards were never after able to recover.

These losses, however, were amply overbalanced by the seizure of the crown of Portugal. The young king Sebastian, who, with most of his nobles, fell in the battle of Alcaçar-quivir, was succeeded by his uncle Cardinal Henry, who, after an uneasy reign of two years, died without naming a successor. Philip, who was one of the competitors for the throne, and had an army ready to act upon the first intelligence of Henry's death, immediately seized upon the kingdom, which submitted without a struggle. This accession to his dominions, however, afforded him little satisfaction. Portugal had been drained of its wealth and population by the unfortunate expedition of Sebastian: and though Philip went in person to Lisbon, where he resided for some time, and conferred many powers upon the nobility, yet finding that all his efforts to gain the affections of his new subjects were fruitless and ineffectual, he returned home in displeasure, leaving the management of the kingdom to a regent and council.

The attention of Philip was now directed to a more formidable enemy, the queen of England. Having, in the early part of his reign lost his consort queen Mary, he offered his hand to her successor; but that prudent princess, who wished not to make an enemy of so powerful a monarch in the commencement of her career, returned a respectful but evasive answer. The measures of her government, however, soon convinced him that he had nothing to hope for on that head; and he soon after married the sister of the king of France. No open rupture occurred between the two courts before 1569; and this was followed by no material consequences until about fifteen years afterwards, when the Spanish monarch, enraged at the assistance afforded by Elizabeth to his rebellious subjects in the low countries, and at the depredations committed by her fleets, not only on his settlements in America, but even on his own coasts, where Sir Francis Drake destroyed about a hundred vessels in the road of Cadiz, and captured an East Indiaman of great value, bent the whole force of his empire to revenge these repeated insults. Great preparations were consequently made for this purpose; and the invincible Armada was sent forth with the confident hope of crushing at one blow these presumptuous islanders and their heretical queen. The fate of this armament is well known, (See Armada;) and Philip now found his attention sufficiently employed as protector of the Catholic league, which opposed the accession of Henry IV. of France; and with his own ambitious schemes for the exaltation of his own daughter, the infanta Isabella, to the throne of that kingdom. But the conversion of Henry to the Catholic faith destroyed all his views in that quarter.

During this period the English had not been inactive in retaliating by deeds the threats of Spain. Corunna was sacked, Lisbon endangered, and saved only through a misunderstanding between the English commanders, and the outward-bound India fleet in the port of Cadiz plundered and destroyed. These losses and insults instigated Philip to another attempt upon England, which, however, was similarly unfortunate as the former, the elements seeming to combine with his enemies in discomfiting his best laid and most confident plans. This was the expiring effort of his reign. He died in the following year, leaving Spain drained of her wealth and her populatiou; for it happened with this prince that while he meditated the destruction of other kingdoms, the very means which he employed exhausted his own.

Philip III. had neither the ambition nor the abilities of his father; and both from his education and dispositions, was altogether incompetent to manage the weighty concerns of an extended empire. He consequently gave himself up entirely to the direction of his favourite the duke of Lerma, who, though not endowed with splendid talents, possessed great prudence, mildness, and moderation. His accession to the throne was immediately followed by the ratification of a peace with France, and in a few years afterwards with England. The contest in the low countries, which occasioned such a waste of troops and treasure, as was gradually wearing out the strength of the monarchy, became also the subject of consideration; and a truce for twelve years was concluded, in which the Dutch republic was acknowledged as a free state. This disposition, on the part of the king's advisers to adopt moderate and pacific measures, promised that tranquillity to Spain of which she stood so much in need for recruiting her resources and restoring vigour to her government. But unfortunately the spirit of intolerance still predominated in her councils, which was encouraged by the bigotry of the priesthood, and the superstitious fears of her monarch; and which led, in spite of the vigorous opposition of the barons and landholders, to the expulsion of the Moors, a measure both impolitic and inhuman, and which lost to the state 600,000 of its most industrious and wealthy population.

Spain still maintained her superiority in Italy, but with difficulty and at great expense; and the intrigues and ambition of her governors in that country rendered her authority odious and insupportable to the Italians.

The disgrace of the duke of Lerma, through the intrigues of his own son, who succeeded him in the affections of the king, produced little change in the foreign policy of the kingdom; but the death of Philip soon after threw the administration of affairs into other hands, who, disdaining the pacific measures of their predecessors, were eager in the prosecution of plans of aggrandizement.

The same system of favouritism still prevailed, and Philip IV. entrusted all to the Count d'Olivares, a man of considerable talent, but boundless ambition. The political horizon of Europe had continued tolerably serene during the last reign; but it now began to be overcast; and the eventful contest of the thirty years war had already commenced. Dissensions in Germany and Italy called for the interference of Spain; and the renewal of the war with the Dutch republic, notwithstanding that power evinced a strong disposition to prolong the truce, or even to convert it into a solid peace, demanded exertions which the diminished resources of the government were little able to support. The policy of Olivares was ruinous to his country. It excited the resentment of all her neighbours, who, without the ceremony of a general alliance, concerted to attack her on every side; and although she suffered little from their hostility, yet being compelled to exert herself beyond her strength, she was shaken to the foundation. New exactions from the people already overburdened, and disorders abroad, increased the general discontent, which, being accompanied by the revolt of the Catalans, the revolution in Portugal, and a series of ill-fortune in the Netherlands, brought her to the very brink of ruin. The removal of Olivares led to the adoption of more moderate measures. Peace was concluded with the Dutch; and though the war was continued with France, she was greatly relieved by the civil discords which arose in that country during the minority of Louis XIV. The Catalans, who had been treated with greater severity, had thrown themselves into the arms of that power, by which a foreign enemy was admitted into the heart of the kingdom. This unnatural contest was prosecuted with various success until 1652, when Don John of Austria, a natural son of the king's, compelled the surrender of Barcelona, when the whole country, except Rosas, followed the fate of the capital.

The great efforts made for the recovery of Portugal and the constant supplies required in other quarters had completely exhausted the treasury, which occasioned considerable embarrassment in the affairs of government. Most of the revenues were anticipated, the people impoverished, and, what added to her misfortunes, the Spanish galleons were burnt by the English fleet under Admiral Blake. In such circumstances peace became absolutely necessary, and accordingly the treaty of the Pyrenees was concluded in the beginning of 1660, in which it was stipulated that the French king should receive the hand of Maria Theresa, the eldest daughter of Philip; but under the express condition that she should, for herself and issue, renounce all right to her paternal inheritance.

The remainder of Philip's reign was employed in an ineffectual attempt to recover Portugal, and at his death he left the kingdom in a most critical situation. His ministers were in absolute disgrace with the people; his successor, Charles II., a sickly infant in the fourth year of his age, and the queen-mother, whom he had appointed regent, inordinately fond of power, but without talents requisite to govern a great and turbulent nation. This princess was the sister of the reigning emperor, and consequently entirely devoted to the interests of the court of Vienna. The first act of her authority was to place at the head of her council her confessor, father Nitard, a jesuit of low birth, of very moderate talents, and totally unacquainted with public affairs. At a juncture when the greatest circumspection and fortitude was necessary to uphold a sinking kingdom, the incapacity of the minister, and the unsteadiness of his mistress, soon excited general discontent, and the nation looked to Don John of Austria as the only person capable of relieving them in their difficulties. This prince possessed great abilities both as a statesman and a soldier, and was besides respected by the nobles and beloved by the people. But the queen-regent, jealous of his superior talents, had prevailed upon her late husband to exclude him from any share in the administration, and now formed the design of sending him from the kingdom, by appointing him to the government of the Netherlands.

In this distracted state of affairs, the government was somewhat relieved by a peace with Portugal, the acquisition of which, from the aversion of the inhabitants to a Spanish yoke, had all along been an embarrassment rather than an advantage to the nation, whereby the independence of that kingdom was acknowledged. But Louis XIV. who had now begun his career of ambition and injustice, in defiance of the treaty of the Pyrenees, claimed the Netherlands in right of his queen, and without waiting to negotiate, made a sudden irruption into Franche Compte, and would soon have overrun the whole of that province, had not the triple alliance between Britain, Sweden, and the Dutch republic, one of the boldest political measures of that age, commanded the peace of Aix-la-Chapelle. By this treaty, however, Spain was compelled to cede some of her strongest fortresses between the Channel and the Scheldt, which so roused the popular indignation, that Don John found little difficulty in driving father Nitard from the national councils and from Spain. The queen-regent, however, resisted every attempt to admit the prince to a share of the government; and in order to remove him from court appointed him viceroy of Aragon.

The loss of father Nitard was soon supplied by another favourite Don Fernando de Valenzuela, equally inexperienced and unqualified for the situation of a minister, and whose vanity and presumption led to the expulsion of his mistress from the helm of the state. The king having attained his fifteenth year, the term of his minority, threw himself into the arms of Don John, who was received by the people as the preserver of his country. The perplexed state of affairs, however, made it no easy matter for the new minister to maintain his popularity. The country had entered into another contest with France in support of the Dutch, which was attended with disappointment and disasters, and the peace of Nimeguen in 1678 added only to their losses in the Netherlands. This was followed by the marriage of the king with a French princess, a measure highly objectionable to the nation, whose principles and feelings were at all times hostile to the name of France, and this circumstance was employed by the enemies of the minister to ruin him both with the king and the people. Their intrigues were too successful. Don John oppressed with chagrin and disappointment, fell sick and died of a broken heart, and with him the sun of Austria set for ever in Spain. The death of this prince, whose abilities, disinterestedness, and noble nature, rendered him the only hope of the monarchy, threw the government into great confusion. The king overcome by a hypochondriac malady, bordering on insanity, was totally incapable of business, and the new minister, the duke of Medina Cœli, though possessed of a good capacity and the best intentions, was unable to remedy so many evils. "The misery of the court was so great, that many of the king's menial servants left the palace for want of subsistence; and the king, with the advice of his council, was not able to find money for the annual journey to Aranjuez. The navy sunk to nothing, the funds destined for its support being diverted by those whose duty it was to supply them. The soldiers deserted on the frontiers for want of pay, and at last the governors quitted the fortresses, to come and represent at Madrid, in person, what they had often represented by letter to little or no purpose."

In this distracted and powerless condition, the king of France, whom no treaty could bind, commenced again his plan of spoliation. Spain having in vain endeavoured to engage the other powers in her defence, submitted to a truce for twenty years, with a farther loss of part of her territories. The queen-mother, who had been imprisoned in a convent in Toledo, and had returned to court upon the death of Don John, again assumed the ascendency in the councils of her son; and upon the death of the queen hastened the marriage of the king with an Austrian princess.

The violent encroachments, and shameless perfidy of the French monarch at last called for the league of Augsburgh, and plunged Europe into a general war, which raged for nearly ten years; and the peace of Ryswick found Spain distracted by internal intrigues respecting the succession of the crown. Charles, with a constitution naturally weak, was fast declining, and there was no hope of a lineal heir to the throne. In the event of his dying without issue, the principal competitors were the Dauphin of France, in right of his mother Maria Theresa, the daughter of Philip IV. though that princess upon her marriage had renounced all claim to the succession: The archduke Charles, second son of the Emperor Leopold, who was the son of Maria Anne, daughter of Philip III., and the Prince of Bavaria, whose mother was the only child of the infanta Margaret Theresa, daughter of Philip IV. France and Austria had both ministers at the court of Madrid, who were instructed to employ every method to induce Charles to make a will in favour of their respective families. But Louis, who at first had little hope of success, and was perfectly aware of the injustice of his pretensions, formed the design of securing a portion of the Spanish dominions to his own family, whatever might be their destination by Charles. For this purpose was negotiated the famous partition treaty between France, Great Britain and Holland, which, when known in Spain, excited universal indignation. By this treaty, Spain and the Indies, with the Netherlands, were assigned to the prince of Bavaria, Naples and Sicily, with some smaller dependencies, to the Dauphin, and Milan to the archduke. But the death of the prince of Bavaria rendered a new arrangement necessary, which substituted the archduke for the Bavarian prince, and Lorraine was added to the share of the Dauphin, Milan being given in exchange to the prince of that duchy. The emperor, who had remonstrated against both treaties, conceiving himself the sole and indubitable heir to the whole Spanish monarchy, was allowed three months to declare his acquiescence. While these schemes of spoliation, however, were in contemplation, the struggle between the contending parties at the court of Madrid continued to be prosecuted with great keenness. The Cardinal Portocarrero, whose personal influence with the king was of the greatest importance at this crisis, was gained over to the French interest. At his instigation, and by the advice of the pope, Charles, worn out by disease and chagrin, was induced to make a will in favour of Philip, duke of Anjou, the second son of the Dauphin of France, the signing of which he survived only one month.

Remarks.—At the commencement of this period, Spain possessed within herself all the sources of agricultural and commercial wealth. Separated by a natural barrier from the other continental powers, and at peace with the world, she had little interest on account of her situation, in augmenting her empire; and it required only a period of repose, and the fostering care of her rulers, by encouraging industry and consolidating an economical system, to render her formidable and respected among the nations of Europe. But the ambitious schemes of Charles I. and Philip II., whose names have been blazoned in the annals of the world, were most injurious to the peace and prosperity of their country. Instead of employing its population and its wealth in improving industry and in spreading cultivation to the deserted portions of its lands, its sons were sent to perish in making fruitless conquests, and its resources exhausted for the interest of their other dominions. And the only return which it received for this sacrifice of blood and treasure, was the ruin of its commerce and manufactures.

The impulse given to industry by the regulations of Ferdinand respecting the admission of foreign cloths, continued for a time to give life and vigour to the national manufactures, and while the Moors remained in the country, Spain could still boast of the excellence of her fabrics. But even then there was little exportation; and during the boasted reigns of the first monarchs of the house of Austria, the Spaniards were still tributaries to the industry of other nations. The whole trade of the Castiles consisted in the exportation of wool, iron, wine, oil, and other raw materials; and in the list of duties paid by the company of Burgos merchants, it does not appear that they exported a single manufactured article. In the middle of the sixteenth century, the quantity of wool sent to Bruges amounted annually to between thirty-six and forty thousand bales, which, after being manufactured, was sent back and distributed over Spain. Besides these cloths, Spain received from the Low Countries, linens, cambrics, cotton and muslin stuffs, Oudenarde and Brussels' carpets, &c. and an immense quantity of hardware. The importation at the same period, of silks, velvets, and brocades from Italy, and hardware, glass, and gold and silver articles from Lombardy and Germany, was very considerable; and also muskets and other military weapons. In 1534, on the eve of a war, it was necessary to import from Flanders gunpowder and even timber for artillery carriages; and to bring carpenters from Italy to make them. Exportation was then confined to articles of the first necessity, a little dressed leather and cloth in inconsiderable quantities. "All the demands of the Cortes," says Laborde, "from the commencement of the sixteenth century, tend to the prohibition of all those commodities which, they said, robbed the country of the treasures which they sent for to the new world." "Lombardy had another kind of traffic no less injurious, that of lending its money at exorbitant interest. Spain was thus tributary to the Lombards on the one hand, and to the Flemings on the other, though the mother country of both. It is evident how irksome this state of things became to the Spaniards by the repeated rebellions that took place under Charles I. and by the opposition made to granting him the subsidies he demanded for his foreign wars, while he could easily have obtained them by an amelioration of the country. The deputies of Castile spoke openly on the subject in 1527, and refused every grant; the petition of the Cortes of Valladolid in 1542 runs thus: "Your majesty's enterprises in Germany and in Italy have drawn into this country an enormous number of foreigners, who, not satisfied with the exchanges, commissions, and profits they make, and that your majesty allows them, have monopolized every kind of commerce by which your subjects gained their livelihood. They do not confine to themselves farming the estates annexed to bishoprics, lordships, official revenues, &c. and to making a profit of landed property; they even go so far as to buy up wholesale, wool, silk, iron, and other raw materials; thus cutting off all the means of existence from the greater part of your subjects, who see with grief what belongs to them go into the hands of those covetous people." The Spanish merchants, discouraged by the advantages which the foreigners possessed over them, and by the capitals of which those persons had the disposal, resigned all business to them. Damien de Olivares says, that in 1610 there were 160,000 foreigners in the Castiles, and among these 10,000 Genoese, who filled almost all the lucrative places, and transacted all the business of the country. The representations of the Cortes, however, and of many of the principal cities of the monarchy; and even the prohibition of the sovereign, were rendered of little effect from the low state of the finances, which made it necessary to augment the public revenue by custom-houses, and to permit importations.

In this wretched state of the kingdom, the principal aim of the government seemed to be, the devising of means to procure money; and while its demands were most exorbitant, the system of taxation was most oppressive and vexatious. The whole revenue of the state was inadequate to defray even the interest of the debt contracted by Charles in his ruinous wars; the rebellion in the Low Countries cost his son Philip above twenty millions Sterling; and this monarch, who had given assignments upon the revenue for sums borrowed from foreign bankers and his own subjects, was under the necessity of superseding these assignments, and thus in a manner becoming bankrupt. The constant influx of specie from the American colonies kept up for a time the apparent prosperity of the kingdom, but this was also absorbed in fruitless and expensive expeditions; and the galleons were as anxiously looked for as if the safety of the monarchy depended on their arrival. This disastrous state grew much worse under the last sovereigns of the house of Austria. In the reign of Charles II. the settled revenue of the kingdom was anticipated for several years; and what was still worse, the officers of the crown did not bring into the treasury above one-tenth of what they levied from the people. Following the steps of their predecessors without possessing their abilities, they completed the ruin of the kingdom; and such was the state of apathy into which the country had sunk, that the potentates of Europe had signed a treaty of partition, and impatiently waited for its spoliation.

While manufactures and commerce were thus suffering from the baleful policy of the government, agriculture was equally neglected. One great obstacle to its improvement was the want of labourers to till the soil. The plague, which made such dreadful ravages in Spain during the fifteenth and sixteenth centuries, left extensive districts without an inhabitant; and we learn from the account of Miguel Martines de Leyva, "that, for a century after, the lands were seen lying waste, and the villages empty; nor have the disasters then sustained been repaired since that period." That little attention was then paid to cultivation appears from a rescript of Philip II. in 1594, which begins thus: "We have been informed that the husbandmen are in want of seed to sow their lands, and of cattle to plough them; that the earth being badly cultivated does not return what it ought, and that persons possessing farms reap no advantage from them." But though this prince granted the title of nobility, and exemption from military service to such as would devote themselves to the study of agriculture, yet this law was never put in execution, for the agriculturists obtained no honourable distinctions, and upon them also principally fell the weight of military service.

With respect to its political state, Spain lost her own liberties while attempting to enslave other nations. At the commencement of the sixteenth century, her institutions were more favourable to freedom than those of any other of the great European kingdoms. The royal prerogative was greatly circumscribed by the privileges of the nobility and by the pretensions of the commons. The military power was lodged in the hands of the nobles, who appeared in the field at the head of their vassals, and without whose assistance the authority of the monarch was feeble and precarious. The inhabitants of the cities also possessed valuable immunities, and were admitted to a considerable share in the legislature. They had acquired the arts of industry, and had accumulated wealth by engaging in commerce. Free and independent themselves, they were ever ready to act as the guardians of public freedom and independence. "Their representatives in the Cortes were accustomed with equal spirit to check the encroachments of the king, and the oppression of the nobles. They endeavoured to extend the privileges of their own order; they laboured to shake off the remaining incumbrances with which the spirit of feudal policy, favourable only to the nobles, had burdened them; and conscious of being one of the most considerable orders in the state, were ambitious of becoming the most powerful." These orders, with the clergy, constituted the Cortes, and in this assembly alone resided the power of making laws, granting subsidies, &c. When Charles, therefore, came to the throne in the lifetime of his mother Joanna, and assumed the title of king, he found great difficulty in prevailing upon this body to acknowledge him in this capacity. The Aragonese looked upon him only as the son of their queen, and opposed the assembling of the Cortes in his name. They at last, however, acknowledged him under the title of king in conjunction with his mother, but bound him by a solemn oath, which they exacted from all their kings, never to violate any of their rights or liberties. The Cortes of Castile proposed that, before acknowledging him as their sovereign, he should promise to observe the laws made at Burgos seven years before; viz. that no foreigner should be capable of any dignity or employment in church or state in Castile, and that no money should be sent out of the kingdom. But this was overruled, and a free gift of 600,000 ducats granted him, after which he promised to observe the laws, and more especially those on which they most insisted. The promises of Charles, however, were given without any intention of fulfilling them; and during the greater part of his reign there was a constant struggle between him and the Cortes; the one demanding subsidies, and the other a redress of grievances; and often separating without agreeing to either. Had the different orders of the Cortes been true to each other, they must have at last prevailed; and might have prevented those unhappy foreign wars which brought the kingdom to such poverty and weakness. For while the cities were forward in stating their grievances, and demanding redress with that boldness which is natural to a free people, the nobles, instigated by a mean jealousy of that spirit of independence which they saw rising among the commons, stood by in silence, and discovered neither the public spirit nor resolution which became their station. When Charles summoned the Cortes of Castile to meet at Compostella instead of Valladolid, the commons remonstrated against the legality of the assembly in that place, and resisted all the arts of the courtiers to influence their vote. But the nobility, who were now desirous of court favour, in opposition to the voice of the nation, granted every demand, without obtaining the redress of any one of the many grievances of which the people complained. The consequences of this was a civil war, which not long after threw the kingdom into such violent convulsions as shook the throne, and almost overturned the constitution. On this occasion the confederated cities put forth a remonstrance, containing a long list of grievances, and some regulations which they thought necessary for their own safety and that of the constitution. Among other things, they demanded that the king shall reside within the kingdom, or appoint a native regent; that no foreign troops shall on any pretence whatever be introduced into the kingdom; that none but natives shall hold any office or benefice in church or state; that no member of the Cortes shall receive an office or pension from the king, either for himself or for any of his family; that each city or community shall pay a competent salary to its representative during his attendance on the Cortes; that the Cortes shall assemble once in the year at least, whether summoned by the king or not; that neither gold, silver, nor jewels, shall be sent out of the kingdom; that the lands of the nobility shall be taxed equally with those of the commons; that all the privileges of the nobles, prejudicial to the commons, shall be revoked; and that no man shall be compelled to purchase papal indulgences.

In this contest the government, assisted by the nobles, was victorious; and this "bold attempt of the Commons," says Dr. Robertson, "like all unsuccessful insurrections, contributed to confirm and extend the power of the crown, which it was intended to moderate and abridge. The Cortes still continued to make a part of the Castilian constitution, and was summoned to meet whenever the king stood in need of money; but, instead of adhering to their ancient and cautious form of examining and redressing public grievances before they proceeded to grant any supplies, the more courtly custom of voting a donative in the first place was introduced, and the sovereign, having obtained all that he wanted, never allowed them to enter into any inquiry, or to attempt any reformation injurious to his authority. The privileges which the cities had enjoyed were gradually circumscribed or abolished; their commerce began from this period to decline, and becoming less wealthy and less populous, they lost that power and influence which they had acquired in the Cortes." The Cortes, however, were not always so submissive to the will of the monarch. On several occasions they peremptorily refused any supplies, and resisted all the solicitations and threatenings of the king. In 1539, when the exigencies of Charles were at the utmost, he proposed to establish a general excise upon commodities; but the nobles, who had now begun to see, with regret, the miseries which their acquiescence to the will of the monarch had entailed upon the country, that it was drained not only of its wealth, but of its inhabitants, in order to prosecute quarrels in which it was not interested, and to fight battles from which it could reap no benefit; and also to feel that the most valuable and distinguished privileges of their order—an exemption from all taxes—was about to be wrested from them, opposed the measure so steadily, by the persuasion of the constable of Castile, that the scheme miscarried, when Charles dismissed the assembly with indignation. This disappointment of Charles was accompanied by another still more mortifying to a prince of his temper. As he was returning from a tournament on the plain of Toledo, one of the harbingers, in clearing the way for the king, struck the Duke of Infantado's horse with his baton, when that proud noble drew his sword and cut him over the head. Such an outrage in the presence of the sovereign called for immediate punishment, and the provost of the household was ordered to arrest the duke; but the constable of Castile interposed, asserting that it belonged to his office to take cognizance of such offences, and conducted Infantado to his own house. The other nobles applauded the boldness of the constable, and retired with him and the duke, leaving the king unattended except by the Cardinal Tavera, with whom he was conversing at the time. Charles, however mortified, saw the danger of irritating a jealous and high-spirited body of men, and had the prudence to conceal his displeasure. He even sent next morning to Infantado, offering to punish the person who had affronted him; but the duke pardoned the officer, and gave him five hundred ducats as a compensation for his wound. Charles, however, by degrees broke the power of this formidable body, and left them nothing but the vain distinction of being covered in the presence of their sovereign. From that "period neither the nobles nor the prelates have been called to the Cortes, on pretence that such as pay no part of the public taxes should not claim any vote in laying them on. None have been admitted but the procurators or representatives of eighteen cities. These, to the number of thirty-six, being two from each community, formed an assembly which bore no resemblance to the ancient Cortes, and became rather a junto of the servants of the crown, than an assembly of the representatives of the people. Philip II. persevered in the same system. Taking advantage of an insurrection in Aragon, he curtailed many of their privileges, and abolished the office of Justiza, which extinguished the liberties of that kingdom; and so successful was he in extending the royal prerogative, that, during the reigns of his successors of the house of Austria, the will of the sovereign became the supreme law in all the kingdoms of the monarchy.

Chap. V. *Spain while subject to the Bourbons.*

Upon the death of Charles II., the junta of regency immediately assumed the functions of government; and communicated to the king of France the testament of their late sovereign. Louis, aware of the glaring violation of his most solemn engagements with respect to the treaty of partition, pretended to hesitate about accepting the will in favour of his grandson; but his scruples were easily overcome, and Philip was conducted to the frontiers to take possession of the Spanish crown. The reception of the young monarch was most cordial and joyful. He made his public entry into Madrid with all possible magnificence, surrounded by exulting and admiring crowds, who contrasted his youthful and prepossessing countenance with the decrepitude and gloomy melancholy of their former sovereign. His title was acknowledged not only by the distant provinces of the monarchy, but by the maritime powers who had been parties to the treaty of partition. But while Philip seemed in quiet possession of the throne, the Emperor of Germany issued a bold and vehement remonstrance against this act of usurpation on the part of France; and "questioned not only the authenticity of Charles' will, but the right of that sovereign to make such a disposition, which was contrary to the acknowledged claims of his family, and the solemn obligation of treaties." This was immediately followed by vigorous preparations for war; and before the conclusion of the year, the emperor was joined by England and Holland, and sometime after by Portugal, who formed what was called the grand alliance, the object of which was, to secure satisfaction for the claims of Austria upon the Spanish monarchy, and to prevent the union of the crowns of France and Spain under one government. Louis had foreseen the issue, and was prepared for it; but the deplorable state of Spain—her revenue exhausted, her fortifications in ruins, without garrisons, or magazines, and her naval and military establishments almost annihilated,—precluded any hope of efficient support from that quarter; and convinced him that the preservation of the crown of Spain for his grandson, must depend chiefly upon his own exertions. He had commenced the war in Italy with considerable success, but was checked on the side of Flanders by the talents of Marlborough. The war was at first confined to the distant provinces; but the internal tranquillity of the Peninsula, began soon to be disturbed by the impolicy and imprudence of the Spanish rulers.

Portocarrero, thinking no reward too high for his services to the house of Bourbon, had absorbed all the influence of the crown, and directed every measure of the state. A thorough reform was indeed requisite in every department, particularly in the finances; but the attempts of the minister, which were confined chiefly to the suppression of various offices and places under government, and the withdrawing of pensions, which the piety of former sovereigns had granted for the subsistence of poor widows, and the maintenance of charitable institutions, produced a very trifling saving, while it involved numerous families in embarrassment and ruin. The Spaniards had formed very extravagant notions of the wisdom and energy of the new government, and flattered themselves that their country would resume all its pristine splendour, without sweeping away those abuses and encumbrances which had been accumulating for ages. This impolitic parsimony therefore tended only to excite discontent among the people; and the attachment of Philip to French customs and manners, and the admission of the peers of France to the same rank and honours as were enjoyed by the grandees of Castile, disgusted and alienated the high-spirited nobles. The spirit of disaffection to the new dynasty was aggravated by the destruction of a French squadron and the Spanish galleons, in the harbour of Vigo, by the Duke of Ormond; and by the defection of some of the principal grandees, among whom was the Duke of Medina de Rio Seco, admiral of Castile, "whose vast possessions, splendid talents, and high descent, rendered him one of the most powerful and distinguished members of the nobility." At the same time the Spanish cabinet was torn by personal feuds and petty cabals. The princess Orsini, camarera mayor to the queen, was a woman of superior talents and attractions, and had gained such an ascendency over both their majesties, that no affair of importance was transacted without her knowledge and advice. Though devoted to the court of Versailles, both from self-interest and gratitude, yet she soon perceived the evil effects of that despotic control which the French monarch was labouring to acquire in the councils of his grandson. She therefore resolved to employ all her influence in organizing an administration entirely Spanish, "to level all the distinctions of Austrian and Bourbon partisans, and to admit into all places of trust persons of known talents and capacity." Such a plan was well calculated to promote the welfare and the independence of Spain. But the French ambassador, who wished to arrogate to himself the whole direction of affairs, represented to his master that the interference of the princess was most hurtful to the French influence, and that the king was completely under her control. This gave occasion to endless wrangling and recrimination. Nor was this confined to one or two. "The whole court seemed to be involved in one common dispute, each individual striving who should most thwart, or calumniate the others." The public interest was thus sacrificed to personal antipathy and private ambition; and, while in this distracted state, the nation was totally unprovided with the means of defence against a powerful enemy.

The allies, by the persuasion of the admiral of Castile, had resolved to carry the war into Spain, and to set up a competitor to Philip in the very heart of his kingdom. The Archduke Charles was consequently proclaimed king of Spain and the Indies at Vienna, and soon after arrived at Lisbon accompanied by 14,000 British and Dutch troops. This threatened invasion excited a spirit of alacrity and decision in the Spanish government which had been long absent from its councils. An army was hastily embodied and organized, and 12,000 French troops entered Spain under the Duke of Berwick. The allies wasted their time in disputes and inaction, and the events of the first campaign were favourable to the Spanish arms. But this was counterbalanced by the loss of Gibraltar, which was captured by the British, and by the battle of Blenheim, which was hailed by the Austrian party as a prelude to the downfal of the Bourbons.

The feuds in the cabinent continued with greater violence than ever; and at the moment when prompt and vigorous exertions were necessary to resist the increasing force of the allies, a total suspension of business ensued; and the most trifling as well as the most important measures were equally thwarted. This was occasioned chiefly by the recall of the Princess Orsini by the king of France, which so afflicted and irritated the queen, that she secretly obstructed every measure of the French ambassador, and encouraged the cabinet to oppose the exercise of foreign influence, and to demand restoration of the ancient forms. The unpromising state of affairs, however, forced her to yield to the demands of Louis, and a new council was appointed under the auspices of France. But she still resisted all reconciliation, and ceased not to exert all her power for the return of her favourite, which she at length accomplished to the great joy of herself and her husband; and the princess was allowed to new model at pleasure the government and administration of Spain.

The affairs of the allies in the peninsula began to assume a more imposing attitude. Charles had landed in Catalonia with a small body of troops under the

Earl of Peterborough; the citadel of Montjuich was taken by assault in a most gallant style by their general; and was soon after followed by the surrender of Barcelona and the submission of the whole province except Rosas. Valencia and Murcia followed the example of Catalonia; and in these provinces nothing remained to Philip but the fortresses of Alicant and Peniscola. The recovery of Barcelona was now the great object of Philip's exertions. There his rival had established his court, and the fate of Spain seemed to depend upon the issue of this enterprise. Philip advanced into Catalonia with 20,000 troops commanded by Marshal Tessé, and was joined under the walls of Barcelona by the Duke of Noailles with a considerable reinforcement from France. A French fleet also blockaded the port, and prevented all communication by sea. The allies, dazzled with their first success, had neglected the requisite preparations for a siege. They had dispersed their troops in the different fortresses of the province; and 3000 regulars constituted the principal strength of Barcelona. The inhabitants, however, were animated by the presence of Charles, and all ranks vied in devotion to his cause. The Earl of Peterborough also, with a flying camp, kept the besieging army in constant alarm. An extensive city so weakly garrisoned could not have long resisted the efforts of so powerful a force. After a month's operations, during which the citadel had been abandoned, practical breaches were formed in the rampart, and the last decisive assault was about to be made, when the allied fleet appeared in sight. The French squadron immediately withdrew; and Philip was compelled to raise the siege, with the loss of his magazines and artillery, and retreat into Roussillon. There he left the remains of his army, and returning to Madrid, where, notwithstanding his disasters, he was received with sincere affection, he removed the court to Burgos. Saragossa opened its gates to Charles, and the whole kingdom of Aragon submitted without a struggle.

While these disastrous events were occurring in the north, the Duke of Berwick, who commanded on the frontiers of Portugal, was obliged to retire before a superior force, under the Earl of Galway, into the heart of the kingdom, and leave the way open to the capital. The allied army, consisting of 30,000 troops, entered Madrid; but instead of taking advantage of the general consternation, and pushing their conquests into old Castile, which would probably have secured the reduction of the whole peninsula, they wasted their time in waiting for the archduke, who had been loitering in Barcelona and Saragossa, and preparing for a magnificent entry into the capital. The Duke of Berwick, however, was not slow in profiting by these delays. His army, reduced to 9000 men, was stationed behind the Henares, and had been joined by the troops which had retreated from Barcelona, and increased by numerous new levies. With this increase of force, he pushed a detachment to recover Madrid, and having shut up the communication with Portugal, forced the allies to retreat towards Valencia, and by a vigorous and active pursuit, rendered their loss scarcely less decisive than an absolute defeat. The distresses and fortitude of Philip having endeared him to his subjects, he was received at Madrid with an universal burst of joy, far more impressive than the acclamations which had hailed his first accession. During this campaign, while Philip was upon the eve of being driven from his throne, the Netherlands was severed from the monarchy by the battle of Ramilies, and Naples was soon after conquered by the emperor.

Both parties prepared, with increased exertions, to renew the struggle in the peninsula. The Duke of Orleans was despatched from France, with a considerable force, to take the command of the Spanish army; and the allied army in Portugal was reinforced by 12,000 men. But before the arrival of these succours, the fate of the campaign was decided by the battle of Almanza. The Earl of Galway, anxious to anticipate the expected supplies, attacked the Duke of Berwick in his quarters with 30,000 men; but that general, having hastily united his forces, took post in the plain of Almanza; and after a long and well-contested action, the allies were routed with great slaughter, insomuch, that on their arrival at Tortosa, their forces scarcely amounted to 5000, of whom only 800 were infantry. The Duke of Orleans joined the army on the following day, and made such a rapid improvement of the victory, that in less than a month he recovered all Aragon and Valencia, and closed the campaign with the capture of Lerida in Catalonia. The joy for these successes at the court of Philip was heightened by the birth of a prince, who was named Louis Ferdinand, *Prince of Asturias.*

The kingdoms of Aragon and Valencia, which had always been forward in embracing the cause of Charles, were made to atone, in some measure, for their rebellion. In Aragon, the city of Saragossa alone was obliged to pay 45,000 pistoles, and the rest of the kingdom 90,000. The ancient rights and privileges of both kingdoms were abolished, and they were in future to be ruled by the same laws and customs as Castile.

The allies, notwithstanding their severe reverses, were no way backward in prosecuting the contest. The army in Catalonia was strengthened by the arrival of Count Staremberg with a body of imperial troops, and by additional reinforcements from England. But even these would not admit of any offensive operations. They were barely sufficient to fill the vacancies occasioned by the late disasters; and, after detaching a corps to the northern frontier, the Count found them too weak to cope with the victorious army of Philip. On the other hand, however, the plans of conquest formed by the Duke of Orleans were thwarted by the exhausted state of the Spanish treasury. France was able to afford but a scanty supply; and the arrival of the American fleet was anxiously looked for to make up the deficiency. But while in this emergency, intelligence arrived that seventeen galleons had been intercepted by the British squadron off Carthagena, when three of the richest were taken or destroyed, and the rest dispersed. The only fruit of the campaign, therefore, was the capture of Tortosa. The duke then returned to Madrid; but owing to some suspicions of his having a design upon the crown of Spain, he was recalled to Paris.

The repeated reverses of the French monarch constrained him to think seriously of putting an end to the war. The battle of Oudenarde, and the consequent capture of Lisle, had opened a road to the very gates of his capital; and the alarms and discontents of his subjects were heightened by the pressure of famine and pestilence. In these circumstances, peace seemed to be the only alternative; but the demands of the allies were so degrading and dictatorial, that he rejected them with indignation. They insisted, as the basis of a treaty, that the whole Spanish monarchy should be restored to the house of Austria, and that Louis should assist in compelling his grandson to abandon his crown. He, therefore, appealed to the loyalty and honour of his people to preserve him from such an unnatural and degrading condition. Hostilities were continued, but he intimated to Philip his inability, from the distressed state of his own kingdom, to furnish the requisite assistance for maintaining him upon the throne.

In this trying situation, Philip, at the instigation of the Princess Orsini, convened the chief ministers and grandees; and having stated to them the exorbitant pretensions of the allies, the withdrawing of the French troops, and his firm resolution to die in defence of his crown, he appealed to their zeal and affection, and demanded from them assistance and counsel. A burst of enthusiasm broke from the assembly, and they protested, "that duty and affection, no less than allegiance, bound them to maintain the sovereign on his throne." They, however, recommended the immediate dismission of all the French, and the establishment of an administration entirely Spanish, at the head of which was placed the Duke of Medina Celi, who had always been strenuous in his opposition to foreign influence. The enthusiasm of the nobles spread through the nation. Levies of men, and contributions of money and plate, were poured in from all quarters; the clergy also lavished their treasures in the cause, and the people every where flocked to the royal standard. Spain, however, when left to herself, notwithstanding the reviving loyalty of her inhabitants, was too much exhausted to furnish adequate resources for the impending struggle. Philip was still directed by the court of Versailles; for although he avowed his determination of throwing himself into the arms of his Spanish subjects, he never gave his confidence to his Spanish ministers, who soon began to discover that the pretended separation from France was merely an affected expedient to stimulate the zeal of the nation. The preparations for the ensuing campaign were not therefore made with that vigour which the emergency required. The system of finance, which had been planned and rendered efficient under the vigorous control of the French ambassador, became unproductive and even injurious under the unskilful and negligent management of the new ministers; and it soon appeared, that the affairs of the government could not be conducted by them with that energy which was necessary. Some suspicions also falling upon the Duke of Medina Celi, he was suddenly arrested and committed to the castle of Segovia; but his offence was never publicly investigated, and his death, which happened soon after, left this transaction involved in mystery. His successor Ronquillo, upon coming into office, engaged to supply the deficiency of the treasury and the wants of the army.

The following campaign commenced by the advance of Philip with 23,000 men, under the Marquis of Villadarias, to the siege of Belaguer in Catalonia; but all his operations were thwarted by the skill of Count Staremberg; and being straitened for provisions, he was obliged to retire upon Lerida. The allied army having been strengthened by reinforcements from Italy, and joined by the Archduke, followed him across the Segra, and attempting to cut him off from his supplies, came to an engagement near Almenara, when the Spanish army was thrown into confusion, and would have been totally destroyed had not night favoured their escape. Although their loss in battle did not exceed 1500 men, yet a panic spread through the army, and it was with difficulty that they reached Saragossa. Here Philip transferred the command of his army to the Marquis of Bay, who had distinguished himself on the western frontier. But the allies had pressed close upon his rear, and before three days had elapsed, the battle of Saragossa drove Philip from his capital, and gave a temporary triumph to the arms of his rival. The Spanish commander, with a remnant of 8000 men, retreated to Soria, and the king hastened to Madrid. Though he returned a fugitive, without an army or resources, he still possessed the affections of his Castilian subjects; and when he removed the residence of the court to Valladolid, his departure was the signal of a general emigration. "He was accompanied by the greater part of the nobles; above 30,000 persons covered the road to Valladolid; even ladies of the first distinction followed on foot; and scarcely any remained in the capital except those whose age, infirmities, or poverty, did not permit them to remove." When Charles, therefore, entered Madrid, no cheers greeted his arrival, but solitude and silence reigned in the deserted streets, and he was compelled to exclaim, "Madrid is a desert."

The firmness and prudence of Philip seemed to rise with his misfortunes; the Castilian spirit was roused to maintain the national glory and independence; and his subjects vied with each other in lavishing their property and their lives to repair the losses of their sovereign. The arrival of the Duke of Vendome to take the command of the army infused additional energy into their councils. He collected the scattered remains of the Spanish forces, and by the middle of November had a well appointed army of 25,000 men. The troops of Charles had remained in the vicinity of the capital, exhausted by disease and intemperance, and exposed to the incessant attacks of the armed peasantry; and their departure was hastened by the intelligence that a French force, under Noailles, had entered Catalonia, and attacked Gerona. The Archduke hastened to Barcelona with an escort of 2000 horse; and his army immediately after began their retreat towards Aragon. Vendome followed, and by a rapid movement overtook their rear guard, consisting of 6,000 men, commanded by the British general Stanhope, who had taken up his cantonments in the small village of Brihuega. Stanhope, though surprised, prepared for a vigorous defence. He threw up entrenchments in the streets, which he defended with great bravery, and disputed every inch of ground in expectation of being relieved, but he was at last overpowered by numbers, and compelled to surrender prisoners of war. Staremberg being apprised of the attack, hastened, but too late to his rescue; and encountered the Spanish army at Villaviciosa. After a bloody and doubtful conflict, the two armies were separated by the darkness, and Staremberg kept possession of the field of battle; but he had suffered so much during the action, that he spiked both his own cannon and those of the Spaniards, and retreated during the night to Barcelona. Soon after this, Gerona having submitted to Noailles, the Spaniards gradually established themselves in the centre of Catalonia, and menaced Barcelona and Tarragona.

The distresses of France were now come to a crisis: and Louis, with all the energy of an absolute government, was scarcely able to prolong a defensive war. The only resource, therefore, from impending ruin, was peace almost upon any terms. The preceding campaign had been most favourable to the arms of the allies; and had they prosecuted the war during another year with similar success, they would have been able to dictate a peace at the gates of Paris. But the house of Bourbon was saved by the shameful defection of Britain from the principles of the grand alliance. A change of ministry in that country had led to a change of measures most favourable to France and Spain. The overtures of Louis were favourably received, although the resignation of the throne of Spain by his grandson, the great cause of the war, formed no part of them; and the British cabinet, selfishly grasping at the offer of commercial advantages, meanly submitted to commence negotiations without the consent of the other maritime powers, and continued these clandestine transactions, while they were amusing the Dutch with professions of cordiality and confidence. Louis, however, had some difficulty to bring Philip to accede to the proposed terms. The cession of the Netherlands was at first vehemently opposed by Count Bergueck, the minister of Philip; but Louis having gained over the Princess Orsini, his objections were silenced or overruled, and Philip granted full powers to his grandfather to negotiate in his name. The consent of the Dutch to the preliminary arrangements was extorted by the dread that Britain would conclude a separate peace; and Charles, who had been raised to the imperial throne, finding all remonstrances fruitless, did not refuse to take a share in the discussions. The deaths of the Dauphin and his son the Duke of Brittany, which left only the duke of Anjou, a sickly infant, between Philip and the throne of France, threw a new difficulty into the negotiations. Louis, though he tacitly acknowledged, yet was always solicitous to evade one of the preliminary articles respecting the separation of the two crowns. When their union, however, became so probable, the British cabinet demanded the immediate renunciation of Philip for himself and his heirs, of all claim to the crown of France, and a similar renunciation of the Duke of Orleans to the crown of Spain. The king of France at first resisted their demand, and declared that "No power on earth can alter the constitutional law of the kingdom, the prince next the crown necessarily succeeds." But when the allies, by their military preparations, gave undoubted indications of their determination to resume hostilities, Louis, afraid again to trust the fate of his crown to the fortune of war, was compelled to acquiesce, and Philip soon after signed his renunciation in a full council of state, which was ratified and confirmed by the Cortes. The great obstacle to peace being now removed, the negotiations proceeded, and at last led to a general peace, which was concluded at Utrecht, with all the contending parties except the Emperor and Philip. The principal articles with regard to Spain were, that Spain and the Indies should continue subject to the present sovereign: that Gibraltar and Minorca should be ceded to Britain; the Netherlands, Naples, and Milan, with the island of Sardinia to the house of Austria; and Sicily to the duke of Savoy, with the title of King. As the emperor refused to renounce his pretensions to Spain, the decision of the grand question relative to that monarchy between him and Philip, was left to future wars and negotiations.

The war still continued in Catalonia, but as the campaign on the side of Philip was merely defensive, the only event of importance was an unsuccessful attempt of Staremberg against Gerona. The emperor, however, in order to concentrate his whole force on the borders of the empire, entered into a treaty for the evacuation of that principality, in which he laboured to preserve for the Catalans their darling constitution. But Philip would admit of only one form of government in his dominions, and was resolved to abrogate their privileges. All, therefore, that could be attained for these faithful supporters of his cause, was a general amnesty and oblivion of past offences, and a tender of the constitution of Castile in lieu of their own. England also, who had twice pledged herself in the face of Europe to maintain their privileges as the price of their services, meanly shrunk from the fulfilment of their engagements: and the Catalans were left to their fate. Ardently attached to their native customs and laws, and holding in detestation those of Castile, the inhabitants of Barcelona resisted every offer of accommodation, short of the actual acknowledgment of their ancient privileges. Though abandoned by all, they prepared for a vigorous defence, determined to relinquish their liberty only with their lives. Villaroel, who had received the rank of general in the Austrian service, was entrusted with the military command. He had only 16,000 troops besides armed citizens, to oppose the whole army of Philip, supported by 20,000 French, under the renowned Duke of Berwick. But every expedient that skill or valour could suggest, was employed to ensure success in the approaching conflict. All who were unfit for service, the timid, the sickly, and the aged, were removed to the island of Majorca, which also held out against the authority of Philip, the fortifications were repaired and strengthened, the streets barricadoed, and every house converted into a citadel, by piercing the walls for the use of musketry; and, in order to excite the popular enthusiasm, and to strengthen their patriotism with the sanctions of religion, they deposited on the high altar of the cathedral the written promise of the queen of England to maintain their constitution, making a solemn appeal to heaven against the desertion of those, of whose selfish ambition and crooked policy they were about to become the victims.

The Spanish trenches were opened on the 12th of July; on the 30th a lodgement was made in the covert way; and by the 12th of August, breaches were effected in two of the bastions. After a struggle of three days, the assailants obtained a footing upon the rampart; and, while arrangements were making for a general assault, the Duke of Berwick, anxious to prevent a farther effusion of blood in this unnatural contest, and to save the city from the horrors of a storm, repeated the offers of a general amnesty. His compassionate efforts were treated with contumely, and served only to add fuel to their enthusiasm. The signal for the assault was given on the morning of the 11th of September, "Fifty battalions of grenadiers," says Coxe, "commenced the dreadful work, and were supported by forty others. The French attacked the eastern bastion, the Spaniards that of St. Clara and the new gate. The resistance was obstinate even to ferocity. Cannon loaded with grape made the most dreadful carnage in the breaches. Without being able to advance a single step, the assailants perished by hundreds. Fresh troops incessantly arriving, at length overpowered the weaker number of the besieged. The French and Spanish columns mounted the breaches at the same instant, and the French pushed forward into the town. But here the conflict really commenced. Every street was intersected with barricades; every inch of ground was purchased with the sacrifice of lives. Unprovided with means to force the barricades, or fill up the ditches, the assailants were swept away by an incessant fire from every house. At length all obstructions were overcome by torrents of blood. In the heat of the combat, the victors spared not; the Catalans, lavish of life, demanded no quarter. When they were driven into the great square, the assailants deemed the conflict at an end, and dispersed for pillage. But the insurgents, profiting by the moment, returned to the charge; the assailants were driven back to the breach, and would have been again precipitated into the ditch, had they not been rallied by the bravery and exertions of their officers. Again the combat raged with aggravated fury, for the Spanish column, which had penetrated by the other breach, was driven back as the French retreated. Numbers and bravery at length vanquished all resistance. The Spaniards turned their own cannon against them, and additional artillery was brought up to the breach. Yet, though thrown into disorder, they did not cease to combat. The assailants, galled with a continual and terrible fire, by a desperate effort forced the bastion of St. Peter, where the besieged made their principal stand, and turned its artillery against them. In this crisis, the chiefs led them to a new charge, but were repulsed, and Villaroel desperately wounded. Though discouraged by the misfortune of the commander, the besieged still maintained the struggle for twelve hours, in every quarter of the town; and there was scarcely an inhabitant of any age, sex, or condition, who did not share in the defence. The history of this century does not furnish an example of a siege so long and bloody. The women at length retired into the convents; the populace, vanquished and straitened on every side, and unable to defend themselves, did not demand quarter; and the French massacred all without distinction. At this moment, some individuals raised a white standard; and Berwick seized the opportunity to suspend the carnage, ordering the troops to maintain their posts, till he had heard the proposals of surrender. But a sudden cry of "kill and burn" bursting from the ranks, revived the fury of the troops; the streets were again deluged with blood, and the authority of Berwick himself scarcely sufficed to arrest the disorder. Night arrived, and with it new horrors; for in the short interval of suspense, the inhabitants resumed their arms, and again poured a destructive fire from the houses. Deputies at length advanced to the breach to parley with Marshal Berwick, but required a general pardon, and the restoration of their privileges. The marshal contemptuously rejected the demand, and threatened to give no quarter, if they did not surrender before morning. His answer inflamed the spirit of the insurgents; and the combat raged with redoubled fury, a storm of fire pouring upon the assailants from the houses, which, by order of the marshal, had been respited from destruction. This night was one of the most horrible that imagination can form. The marshal ordered the dead and wounded to be removed, kept the troops under arms, and prepared to reduce the town to ashes. Day broke, and notwithstanding the obstinacy of the insurgents, he granted a delay of six hours. This concession producing no effect, the houses were set on fire. Apprised of their danger by the burst of the flames, the insurgents once more hoisted a flag of truce. The fire was extinguished, the deputies of the magistracy yielded the town without condition, and the offers of Berwick procured the immediate surrender of Montjuich and Cardona.

The lives and property of the inhabitants were spared; but twenty of the chiefs, among whom were Villaroel, Armengol, the Marquis of Peral, and Nebot, were consigned to perpetual imprisonment in the castle of Alicante; and the bishop of Albaracin, with two hundred ecclesiastics, banished to Italy. Of the rest, the inferior officers were dismissed on taking the oath of allegiance. The standards of the town were publicly burnt, the privileges of the province annulled, and a new government established, according to the constitution of Castile.

Thus ended a conflict which recalls to recollection the fate of the ancient Numantia and Saguntum, and in recent times finds a parallel in the immortal defence of Saragossa. The royalists purchased their victory with the loss of no less than 6,000 men in the siege, and 4,000 in the assault; and the besieged were equally sufferers.

The fate of Barcelona ensured the submission of Majorca; and Philip now reigned undisputed monarch of Spain. The death of the queen, and the marriage of Philip to Elizabeth Farnese, a princess of Parma, was followed by the disgrace of the Princess Orsini, and her French adherents; and the death of Louis XIV. to whose will Spain had hitherto been subservient, led to the removal of a foreign domination, which gave universal satisfaction to the Spanish people, and produced a temporary tranquillity in the court and kingdom which had long been unknown.

Philip, being now relieved from the control of his grandfather, directed his efforts to the improvement and welfare of his adopted country. The distant branches of the monarchy, which had always been supported at the expense of Spain, and in defence of which she had often lavished her treasure and her population, being lopt off, his attention was confined to the peninsula; and it required only a few years of peace to recruit his resources, and consolidate his power. A hypochondriac malady, however, had weakened his faculties, and had induced such indolent habits, as prevented him from prosecuting his purpose with any degree of consistency or firmness. He was consequently led by those who at any time were fortunate enough to gain his confidence. The new queen had succeeded to all the power possessed by her predecessor and the Princess Orsini, and by her talents and intrigues, governed her doting husband with such authority, that, without seeming to rule, she was, during the whole of his reign, the actual sovereign of Spain. Her chief guide and confidant in the science of politics was Alberoni, one of her own countrymen, and to whom she principally owed her own elevation. This person, by his talents and address, had raised himself from being the son of a poor gardener at Placentia, to the friendship and confidence of Vendome, and after the death of that general, became minister from Parma at the court of Madrid. By his discriminating and intriguing spirit, he soon obtained an ascendency over the sovereigns of Spain; and though he held no other public character than that of agent from Parma, he in fact held the reins of the Spanish government.

As the emperor still persisted in retaining the title and assuming the honours attached to the crown of Spain, Philip was anxious for an opportunity of humbling his rival, and wresting from him his Italian territories, which had been separated from Spain by the treaty of Utrecht. In the prosecution of this scheme, Alberoni endeavoured to obtain the co-operation of Britain. and for this purpose restored to that power all the commercial advantages which it had enjoyed under the former sovereigns of Spain. But professions of amity were all that he could obtain in return; and Britain soon after formed with the emperor and France the triple alliance, which had for its object the preservation of public tranquillity, and the confirmation of the possessions in the treaty of Utrecht, concerning the succession to the two crowns. When informed of this treaty, Philip was filled with indignation, and reproached Alberoni with betraying him; but the wily statesman soothed the irritation of his master with the hope of soon detaching Britain from the alliance; and laboured to protract a rupture until he was better prepared for hostilities. The allies immediately endeavoured to mediate an accommodation calculated to satisfy both parties. Philip, however, refused to renounce his pretensions in Italy, and hastened his hostile preparations. But, while Alberoni continued to temporize with the allies, the war was accelerated by the arrest of the Spanish ambassador at Rome on his return through Italy by the Austrian governor, who confined him in the castle of Milan, and having seized his papers, transmitted them to Vienna. This insult from such a quarter destroyed all hopes of a reconciliation; and Alberoni, having been raised to the dignity of cardinal, pressed the requisite preparations for an expedition against Sardinia, which was completely successful, and that island was again added to the crown of Spain. The war, once commenced, required great exertions, and called forth all the energy of Alberoni. The enthusiasm of the nation was awakened by the success of the Spanish arms; and contributions of money and troops were furnished by the different towns and provinces. By these means he was enabled to make a successful attack upon Sicily. Palermo submitted, and the restoration of the Spanish government was hailed both by the nobles and the people. But the further progress of the Spanish arms was stopt short by the defeat of the Spanish fleet by Admiral Byng in the bay of Naples. The allies still pressed upon Spain the necessity of an accommodation, and Britain even offered the restoration of Gibraltar provided that her sovereign would accede to the alliance. Philip, however, was inexorable, and declared that he would never lay down his arms until Sicily and Sardinia were ceded to Spain. Three months were allowed for the acceptance of their terms, accompanied with a threat, that any farther delay would be followed by a declaration of war.

In the meantime Alberoni had drawn Sweden and Russia into a treaty with Spain, the principal object of which was the invasion of Britain in support of the pretender. But the death of Charles XII. and the appearance of a British fleet in the Baltic, deprived him of all co-operation from these powers; and when an expedition, with 6,000 men, and 30,000 stand of arms, under the exiled Duke of Ormond, left Cadiz for the shores of Scotland, it was dispersed by a tempest off Cape Finisterre, and 300 men only, with a few officers, reached their destination. The other schemes of Alberoni were equally unsuccessful. He had fomented a conspiracy in France, which was encouraged by his master, with the view of removing the Duke of Orleans, and appointing Philip to the regency of that kingdom. The discovery of this plot was immediately followed by the invasion of Spain by a French army under the duke of Berwick, who destroyed the arsenal and stores of Port Passage, took possession of Fuenterrabia and Urgel, and then retired into Roussillon. These reverses compelled Philip to think of peace; but the allies would be satisfied with nothing less than the dismissal of his minister, which, having accomplished, Philip acceded to the quadruple alliance, by which he relinquished all claims to the dominions which had been severed from the Spanish monarchy. Sicily was restored to the emperor, Sardinia to the Duke of Savoy, with the title of king, and the eventual succession of Tuscany and Parma was entailed upon the issue of the queen of Spain. But, while these general arrangements were accepted by the contending powers, many minor claims on all sides were left unsettled as the germs of future disputes, and were referred to a congress to be held at Cambray. The bonds of amity between France and Spain were renewed by the marriage of the young king of France with the Infanta Mary-Anne in her fifth year, and of Louis, prince of Asturias, with a daughter of the Duke of Orleans; and this double connexion allayed the personal animosity which existed between Philip and the Regent, and suspended for a time all political rivalry between the two nations.

The removal of Alberoni deprived Philip of an able servant, whose vigorous intellect, and extent of information it was difficult to replace; and, when he affected to be his own minister, and to conduct the business of the state, he sunk under the weight, and gradually relapsed into his habitual melancholy. The reins of government were then alternately seized by various competitors for power, and had found no master hand to guide them, when Philip suddenly abdicated his crown in favour of his son Don Louis.

The young king was only in his seventeenth year when he ascended the throne. Attached by birth and habit to the Spanish manners, he was welcomed with universal exultation. But his youth and inexperience rendered him unfit to direct the helm of the state; and while he stood as the ostensible head of the government, he possessed no real authority. Philip, who with his queen had retired to the beautiful palace of St. Ildefonso, which he himself had constructed at great expense, enjoyed all the power without the trammels of royalty. He had retained the marquis of Grimaldi as his secretary, and through him regulated the affairs of his son's government. The passive disposition of Louis made him submit for a time to the orders from St. Ildefonso; but the intrigues of his cabinet were directed to his emancipation; and it is probable that he would soon have been induced to assert his right, and to unite the real to the nominal authority of his station, had he not been carried off by the small pox after a reign of only eight months.

The abdicated monarch, anxious to recover that authority which he had never altogether relinquished, hastened, in opposition to his solemn vow,—never to resume the crown, and also to the wishes of his subjects,—to prepare for his again ascending the throne; which, after some affected religious scruples, he was not long in accomplishing. The queen, overjoyed at recovering her crown, directed all her efforts to the accomplishment of her darling object, the reversion of Tuscany and Parma to her son Don Carlos. This subject, however, was received so coldly by the congress at Cambray, that she resolved to negotiate directly with the emperor. She accordingly despatched the duke de Ripperda on a secret mission to Vienna, which he fulfilled in such a way as secured her favour, and set aside for a time the favourite Grimaldi. Forgetting their former rivalry, the two monarchs entered into the closest bands of amity; and the first fruit of this new alliance was the demand from Britain of the immediate restitution of Gibraltar. In resisting this demand Britain was supported by France and Prussia; but their hostilities were confined to diplomatic warfare, until Philip became the aggressor by besieging that fortress. This was followed by lengthened negotiations among all the contending powers respecting a variety of points, which none were willing to concede.

The hypochondriac malady of the king had now increased to such an extent, that it occasionally gained the empire over his reason. In these seasons of distress his mind reverted to the happiness of retirement, and he expressed his determination again to resign the crown. The queen dreading such a measure, removed the residence of the court to Seville. But, eager in the prosecution of her favourite scheme, she continued the negotiations, and at last by her intrigues and perseverance effected her object. Don Carlos was put in possession of Parma aud Placentia, and acknowledged the successor to the Grand Duke of Tuscany.

The disputes respecting Poland raised Philip once more from his stupor, and returning to Madrid, he resumed the duties of government, and joined with France against Austria in support of Stanislaus to the throne of that kingdom. Their united arms were everywhere successful, but he was deserted by France in the midst of victories; and the only fruit of the war was the possession of Naples and Sicily by Don Carlos, in exchange for Parma and Tuscany. The administration of the government during these struggles had been ably conducted by Don Joseph Patino, who has been termed the Colbert of Spain, and was perhaps the most able minister, who since the accession of Philip, had directed the helm of the state. His death was a loss to his country which Philip, during the remainder of his reign, was never able to supply.

The long continued disputes with Britain respecting commercial rights, both in Europe and America, at last involved the two nations in war, the first fruits of which was the capture of 400 vessels, valued at one million sterling, by Spanish privateers. The attacks of the English were directed chiefly against the enemy's possessions in the new world; but they were repulsed with great loss before Carthagena, and also failed in an attempt upon Cuba; and their only reprisals were the taking of Porto-Bello, and the seizure of an Acapulco ship by Anson. Into this contest the other powers of Europe were drawn by the death of the emperor, and the accession of his daughter Maria Theresa. Though almost all of them had guaranteed the Pragmatic sanction, by which this princess was declared heir of all the Austrian dominions, yet few of them were found just enough to support it. Philip, among the rest, regardless of his solemn guarantee, appeared as one of the claimants of the Austrian inheritance, not with any hope of making good his pretensions but for the purpose of obtaining an establishment in Italy for the Infant Don Philip. After a long and expensive war, which was prosecuted with various success, Philip entered into the general negotiations for peace; but before they were brought to a close he was carried off by a fit of apoplexy.

His successor, Ferdinand VI., concluded the arrangements, by which Parma, Placentia, and Guastala were assigned to Don Philip: and the disputed points between Britain and Spain, which were too numerous and complicated to enter into a general treaty, were referred to a particular and separate negotiation. The pacific reign of this monarch was spent in cultivating a good understanding with Britain; and he found an able coadjutor in the upright Carjaval, while the interests of France were supported by the marquis Ensanada. The court of Madrid was the theatre where these contending powers maintained a constant rivalry, each being supported by a party in the government. The death of Carjaval, which threatened the annihilation of the British interests, was well supplied by the appointment of General Wall, who followed the politics of the deceased minister, and by the disgrace of Ensanada, became the sole arbiter of these contentions. This peaceful system, however, was overturned by the death of Ferdinand.

While the other powers of Europe were engaged in war, Ferdinand had maintained a strict neutrality; but Charles III., alarmed by the successes of Britain, and more attached to France than his predecessor, was drawn into an alliance with that power, which was called the "Family Compact." By this treaty, the Bourbon monarchs agreed to guarantee their respective dominions in all parts of the world, and to consider every power as an enemy, who might become the enemy of either. Spain was thus led to share in the misfortunes of her ally. The Havanna, the depository of her treasure, and the principal magazine of her naval and military establishments in the new world, submitted to the British arms, with a booty of three millions Sterling of public property, besides nine ships of the line, and an immense quantity of stores. Manilla surrendered about the same time, and was followed by the capture of the Santissima

Trinidada from that island, worth three millions of dollars.

Portugal, from her alliance with Britain, had also been forced into the war, and presented to the cupidity of Charles an easy and important conquest. But even here his arms were foiled, and his troops were obliged to retire within their own frontier. In this crisis the chivalry of the Spanish character was nobly displayed by the nobility of Aragon, and its ancient dependencies, rallying round the throne, and supplicating their sovereign to accept of their services in defence of their country. "We pray your majesty to accept the half of our forces to carry the war into hostile countries, instead of waiting for the enemy in our own; the other half will suffice to keep them far distant from our shores, should they have the temerity to approach us. We have little concern in regard to the quality of posts which your majesty may assign us, less for the climate whither we may be sent, and none for pay. Those who seek only to establish an incontestible title to the rank of gentlemen, need no reward but an open field to display their valour, and affection for their country." But repeated disasters having exhausted the resources of the Bourbon crowns, they became sincerely solicitous for peace; and the treaty of Paris again restored tranquillity to Europe. By the retirement of General Wall, and the appointment of Grimaldi, a partisan of France, the influence of that power gained the ascendency in the councils of Madrid; and the commercial disputes with Britain, which still remained undecided, occasioned a degree of irritation between the two courts, which required but a spark to kindle it into a war. But while Charles waited only until he could be assured of the co-operation of France, the internal affairs of his own kingdom called for his undivided attention.

Squilaci, the minister of finance, whom Charles had brought with him from Naples, had attempted, in his eagerness for reformation, to change the national dress. An edict was accordingly issued, prohibiting the use of flapped hats and long cloaks, which were supposed to favour assassination, a practice then very common in Spain. He had also established a monopoly for supplying Madrid with oil, bread and other articles of general consumption, which was immediately followed by a rise of price in these commodities. These measures roused the indignation of the populace, and excited an insurrection in the capital so sudden, violent, and powerful, that all attempts to restore tranquillity were unavailing, until Charles himself appeared in the balcony of the palace, and promised to dismiss the Neapolitan minister, to repeal the obnoxious edict, to suppress the monopoly for supplying the city with provisions, and to pardon the insurgents. The equable temper of the king was so ruffled by this tumult that he left the capital, and established his court at Aranjuez, where he resided for eight months.

As similar insurrections had occurred in different parts of the kingdom, Charles began to suspect that they arose from something else than a mere popular ferment; and upon a strict investigation into the circumstances of these disturbances, his suspicions fell upon the Jesuits. The spirit of intrigue and persevering ambition of this celebrated order had obtained for them great influence and power in every Catholic country. As the instructers of its youth, the confessors of its princes, and the spiritual guides of the nobility, they gained such an ascendency over the minds of men that they mingled in all affairs; and there was scarcely a public intrigue or revolution in which they were not actually implicated, or supposed to be engaged. Devotedly attached to the court of Rome, they endeavoured to exalt her dominion over all civil government, and acknowledged no authority that was any way opposed to the maxims of the order or the will of their general. They were thus dangerous as subjects, and by their number and wealth were formidable as enemies; and though they had become objects of fear and jealousy to many of the European governments, yet, until the middle of the sixteenth century, no monarch had been bold enough to set them at defiance. Portugal was the first who set the example, from whence they were expelled in 1759; France followed in 1764; and Spain in 1767; and the manner of their expulsion from this latter kingdom and its colonies, was as complete as it was unexpected. See Jesuits.

Internal tranquillity being completely restored, Charles, with the assistance of the Count D'Aranda, devoted his exertions to domestic reformation and the amelioration of the finances, while Grimaldi was at the same time concerting measures with the minister of France for again embroiling Europe in war. An unfortunate expedition against Algiers, however, drove Grimaldi from the helm, which was entrusted to Count Florida Blanca, who commenced his administration by a war with Portugal. This contest arose out of former disputes relative to their respective boundaries on the Rio de la Plata, and in consequence of these the two courts had been long engaged in angry discussions or actual hostilities. The first aggression was on the side of the Portuguese, who reduced several forts on the Rio Grande, and repulsed a Spanish detachment with the loss of 500 men. But Spain inflicted a severe retaliation by the capture of the isle of St. Catherine, and the colony of Sacramento; and when hostilities were stopt by the death of the king of Portugal, she obtained a very advantageous treaty, and retained Sacramento, which had long been a bane of contention between the two crowns.

Upon the breaking out of the revolution in British America, and the interference of France, Charles pretended to adopt a strict neutrality, and offered his services for the accommodation of their disputes. Partial however, to France, and anxious to crush the maritime power of Britain, which had long been the favourite policy of Spain, he used his mediation merely as a mask, and employed the long interval of the negotiation in maturing his naval and military preparations. He at the same time, in order to secure his object, had formed arrangements with almost every power either at enmity with Britain, or that was likely to be turned against her. Britain stood alone in this contest, and the first attempts of her united foes was the invasion of her territory. Fifty thousand troops were ready for a descent upon her coasts, and the combined fleets, consisting of 68 sail of the line, besides frigates, blockaded the channel, with the hope of intercepting the British fleet under Admiral Hardy. But the British admiral having eluded their vigilance, passed up the channel; and though they followed him above Plymouth, they declined an action in so narrow a sea, and returned to Brest mortified by their failure, and debilitated by hardship and disease. A greater reverse, however, was awaiting them upon their own shores. Gibraltar had ben invested by sea and land, and was reduced to such distress, that the Spanish court looked with confidence for its speedy surrender, when Admiral Rodney was despatched to its relief. Having captured on his passage a convoy of fifteen sail, with naval stores and provisions, he encountered the blockading squadron off Cape St. Vincent, which he defeated with great loss, and threw into the garrison whatever was necessary for its defence. These reverses, however, were in some measure counterbalanced on the side of Spain, by the reduction of the Floridas and the capture of the British East and West India fleets, valued at nearly two millions sterling. In the West Indies their operations were at first equally successful. They had secured almost the whole chain of the Antilles, and were preparing an immense armament, to consummate their enterprise by the reduction of Jamaica, when Rodney, as an evil genius, appeared in its defence, and having defeated the French fleet under De Grasse, saved that island, and in fact prevented the utter expulsion of the British from the Caribean Sea.

The capture of Minorca, after a brave defence, encouraged Charles to prosecute with vigour the siege of Gibraltar, which formed the most memorable feature of the war, and for a period of four years arrested the attention of Europe. All the skill and power of the Bourbon governments were exerted for the recovery of this important fortress: and they had made so sure of success, that two of the French princes repaired from Paris to witness its fall. But the gallant defence of General Elliot, and the admirable manœuvres of Lord Howe, who, in the face of a very superior force, passed the straits, and strengthened the garrison with a reinforcement of 1400 men, besides a supply of ammunition and provisions, rendered all their efforts unavailing, and the cessation of hostilities saved them from any farther disasters. After a long and fruitless negotiation for the cession of Gibraltar, Charles was under the necessity of acceding to other terms, by which he obtained the two Floridas; and kept possession of Minorca, which, next to Gibraltar, had been the great object of national ambition.

Charles had soon cause to regret his erroneous policy in encouraging the revolt of the American provinces. His own subjects in South America endeavoured to profit by the example of the northern states, and an insurrection, headed by a descendant of the ancient Incas, threatened to sever them for ever from the parent state. Tranquillity was at last restored, but the seeds of liberty were then sown, of which they are now reaping the harvest, and the maintenance of the royal authority required an establishment which absorbed the greater part of the American revenue.

The latter part of Charles's reign, under the wise direction of his favourite minister Florida Blanca, was spent in promoting the internal improvement of his kingdom; and the great object of his interference in the general system of European politics, was to secure public tranquillity, and prevent his country from being again involved in new troubles and commotions. He died in the 73d year of his age, and the 19th of his reign. This prince was the only Bourbon sovereign of Spain who was not led by those who happened to surround him. He was perhaps, in general, too pertinacious in adhering to his own opinions and resolutions; but his talents were respectable, his disposition benevolent, his morals irreproachable, and he possessed a manly firmness of temper, which was seldom elated by success or depressed by misfortune. He gave every encouragement to industry and the fine arts, and was a distinguished patron of literature and science. Respected and feared as a sovereign, he was beloved as a man; and those who attended on his infancy, grew grey, or died in his service. His most characteristic propensity was a love of shooting and the chase; and so high was the importance which he attached to his exploits as a sportsman, that he kept a regular account of the victims of his skill. It is said, that a little before his death he boasted to a foreign ambassador, that he had killed with his own hand 539 wolves, and 5323 foxes, adding with a smile, "you see my diversion is not useless to my country." His dress is thus ludicrously described by Swinburne: "It seldom varies from a large hat, grey Segovia frock, a buff waistcoat, a small dagger, black breeches, and worsted stockings; his pockets are always stuffed with knives, gloves, and shooting tackle. On gala-days, a fine suit is hung upon his shoulders; but as he has an eye to his afternoon's sport, and is a great economist of his time, the black breeches are worn to all coats. I believe there are but three days in the whole year that he spends without going out a-shooting, and these are noted with the blackest mark in the calendar. With all his peculiarities, however, he was greatly beloved by his people, and universally received the respected appellation of "the good old king."

Remarks.—When Philip V. took possession of the crown of Spain, he found a kingdom completely exhausted, without a marine or efficient army, without industry or manufactures, with scarcely a remnant of her ancient power, wealth, and grandeur. Owing to the neglect or incapacity of her former rulers, every department of her government was in the most deplorable disorder. Incapable of her own defence, it was only by the assistance of France that Philp was enabled to maintain himself upon the throne. When, by the treaty of Utrecht, the superfluous branches of the monarchy were lopt off, and the integrity of her territories in the Peninsula and America secured, she began to rise into her former importance, and to hold a high rank among the nations of Europe. The constant drain upon her resources required for the support of her dominions in Italy and Flanders, was now shut; and while her expenses were reduced, the revenue of Philip exceeded by one-third that of any of his predecessors. As the whole reign of this prince formed a series of inconsiderable projects, imperfect accommodations, and successive hostilities, he often experienced considerable difficulty in raising supplies. The money, however, which was expended in the war of the succession remained in the country, and the energy which that struggle produced, called forth a formidable army. Her disputes with Britain led also to the establishment of a powerful marine, and the strength of her navy once more awakened the attention of Europe. The revival of trade, industry and the arts, occupied the exertions of some of her ablest ministers. Alberoni laid the foundation of many important improvements, by surveying the different provinces, and ascertaining the state, productions, and resources of the kingdom. He greatly facilitated the interior communications and traffic, by removing most of the inland custom-houses to the frontier; and rooted out a contraband trade of great extent, which had been carried on by the people of Biscay, under the privilege which they enjoyed of trafficking with the manufactures and productions of their own province, free of duty. He diminished the introduction of foreign manufactures, which had hitherto filled the markets, to the detriment of those of Spain, by establishing a manufactory of woollens at Guadalaxara, under the royal patronage, and another of fine linens, in imitation of those of Holland, and by transmitting the strictest injunctions to the different intendants and governors to encourage the use of the native fabrics, and to have all the troops in future clothed with the manufactures of Spain. He also revived the foundry of artillery and small arms, which had fallen into total inactivity; and in the principal ports, he established docks, fabrics of rigging, and magazines. By these and other important regulations he emancipated Spain from her dependance upon foreign nations, not only for articles of almost universal consumption, but, what was of immense consequence in time of war, for the means of naval and military equipment. The short term of his ministry, however prevented him from giving consistency and effect to his various plans of internal policy; but his successors benefited by the valuable legacy, and, in the following reign, many of his projects were completed, and trade and industry greatly relieved from the trammels imposed upon them by interest and ignorance.

During the pacific reign of Ferdinand, the internal improvements of the kingdom were steady and progressive. The collection of the revenue was simplified by abolishing the farming system, which had been found to be both oppressive and inefficient, and by reducing the provincial taxes to a royal administration; and such order and economy was introduced into the finances by Ensenada, that the Spanish treasury had never been so well replenished since the accession of the Bourbons. Improvements in the marine, which had always been a favourite object of the government, were prosecuted with great vigour and success. Timber was collected from Naples and other parts of Europe; foreign shipbuilders and engineers were encouraged to settle in the country: and by fortifying and improving the arsenals of Ferrol, it was converted from a paltry village into one of the noblest ports of Europe. New discoveries and improvements in the arts and sciences were eagerly sought for in foreign countries, and transplanted into Spain. Strenuous efforts were made to revive the national agriculture, by the formation of patriotic societies, and by translating into the Castilian tongue a valuable Arabian manuscript, found in the library of the Escurial, which contained the excellent system of culture pursued by the Moors.

But these were merely preludes to the general system of reform which distinguished the reign of Charles III. and the administration of Florida Blanca, who, with the assistance of Campomanes and other able coadjutors, carried his schemes of amelioration far beyond any of his predecessors. The trade with America, which had been confined to Cadiz, was thrown open to all the Spanish ports, except those of Biscay, which spread industry and activity over all the kingdom, and so multiplied the connection with the colonies, that in a short time the imports and exports were tripled, and the produce of the customs and revenue in both dominions more than doubled. A new impulse was given to the native manufactures, by increasing the duties upon foreign fabrics; and the condition of the industrious classes was greatly meliorated by the abolition or modification of many oppressive taxes. Many charitable and patriotic institutions were established, for relieving the poor, and promoting industry and education among the lower orders; for the encouragement of agriculture and the useful arts; and for the cultivation of literature and science. Most efficient measures were also adopted for the prevention of idleness and mendicity; and the gypsies, a numerous and vagabond race in this country, who were lost in licentiousness, idleness, and vice, were converted into useful and industrious citizens. The difficulties of internal communication, which had always been a great obstacle to industry, and in a great measure prevented the transport of corn and other heavy commodities, were remedied by the formation of roads in the principal provinces, and by numerous canals, which served also for the purposes of irrigation. The labours of the minister were also directed to the administration of justice, both civil and ecclesiastical. By various regulations, he endeavoured to prevent the partiality or misconduct of the subordinate magistrates, and to check vexation, chicanery, and delay in the courts of law; and the formidable tribunal of the inquisition was so shackled and restricted in its operations, that it was allowed to give only such displays of its authority as to render it contemptible in the eyes of the nation, and to prepare the way for its final abolition. The naval and military system felt also the impulse of his beneficial regulation, and never was it marked by a more rapid amelioration than during his ministry. The improvements and changes introduced by this minister were, in fact, so numerous and varied that they extended to almost every department of foreign or domestic policy; and had his patriotic advice been followed, the burdens of the poor and industrious would have been still further diminished, and those odious impositions, the *alcavala* and *milliones*, which may be truly said to have cramped the industry, exhausted the wealth, and hastened the decline of Spain, would have been superseded by taxes less oppressive in their operation. But his dismissal from office in the following reign, by the intrigues of the queen, prevented the completion of many of his plans, and the breaking out of the French revolution turned the attention of the government to its own preservation.

Chap. VI.—*Bonaparte seizes the throne—Revolution in Spain—The French driven from the Peninsula.*

Charles III. upon his death-bed, charged his successor to retain Florida Blanca in his service, as an upright and faithful counsellor, to whose able and unwearied exertions the kingdom was indebted for many valuable improvements. Charles IV., however, held only the nominal sovereignty of Spain, the whole power and influence of the government resided virtually in the queen. This princess was a daughter of the Duke of Parma, and soon after her marriage with the Prince of Asturias, discovered a strong propensity to gallantry, which the severe and jealous temper of her father-in-law was scarcely able to check. But the death of the old king left her without an obstacle in the pursuit of her licentious pleasures, as her weak and good-natured husband seemed neither to feel nor to see her disgraceful conduct. Her favourite at this time was Don Manuel Godoy, a young officer in the horse guards, and descended of an ancient but decayed family in Estremadura. This person had obtained his present elevation by supplanting his brother in the affections of the queen; and he continued, in spite of his own imprudence and infidelities, which were well known to his royal mistress, to maintain his ascendency over her to the last. He had also ingratiated himself into the confidence of the monarch, and was rapidly advanced to the first ranks of the army, and the highest honours of the state. Having been raised to a grandeeship of the first class, he received a princely estate belonging to the crown, with the title of Duke de la Alcudia, and the faithful Florida Blanca was removed to make way for his appointment to the head of the government.

At this period the revolution in France had involved Spain also within the vortex of its influence; but her ill-conducted and disastrous efforts were of little avail to the general confederacy. The revolutionary forces overran the greater part of Navarre, and would soon have dictated their own terms at Madrid, had not the favourite minister concluded and ratified the peace of Basle, by which the French conquests were restored in exchange for the Spanish part of St. Domingo. The nation had been so alarmed at the successes of the republican army, that this peace was hailed with universal joy, and no reward was considered too extravagant for the person by whose management it had been accomplished. A new dignity was created for him alone, under the title of "Prince of the Peace," which placed him next in rank to the princes of the blood royal: and this was soon after followed by his marriage into the royal family, by receiving the hand of the eldest daughter of the king's late brother Don Louis.

The open and unguarded gallantries of the favourite, however, excited the jealousy of his royal mistress, and she frequently formed the design of accomplishing his disgrace, and driving him from the court; but her unextinguished, and ever reviving passion, yielded to the first offers of reconciliation; and all her attempts at revenge ended only in the ruin of those who were employed as the instruments of it. It was this which deprived Spain of the talents of the accomplished and patriotic Jovellanos, and consigned him to the fortress of Bellver in Majorca. The return of confidence was always followed by an accession of honour and influence. The antiquated dignity of high admiral, accompanied with great emoluments, and the title of highness, was revived and conferred upon Godoy, and a brigade of cavalry, composed of picked men from the whole army, was given him for a body guard. His power at length became so unlimited, that every department of the government was filled by his dependents; and it is said, that "the queen finding it impracticable to check his gallantries, had so perfectly conquered her jealousy as not only to live with him on the most amicable terms, but to emulate his love of variety in the most open and impudent manner."

It could not be expected that a country under such control could long maintain its respectability and independence. The incessant demands of the queen for the support of her pleasures, formed the most pressing and considerable item in the Spanish budget: and it is asserted that "Caballero, the minister for the home department, fearing the progress of all learning, which might disturb the peace of the court, sent a circular order to the universities, forbidding the study of moral philosophy. 'His majesty,' it was said in the order, 'was not in want of philosophers, but of good and obedient subjects.'" Spain consequently became the humble tool, first of the republic and then of the Emperor of France. Soon after the peace of Basle, she entered into an alliance with the republic, to which she furnished a fleet and large contributions in money; but in her contest with Britain, her fleet of twenty-seven sail of the line was defeated off Cape St. Vincent by a very inferior force, under Sir John Jarvis, when four line of battle ships remained with the victors.

Upon the renewal of hostilities after the peace of Amiens, Spain, as a vassal state, again attached herself to the fortunes of her more formidable neighbour,—but the battle of Trafalgar stripped her of her marine, and she continued to be the passive instrument of Bonaparte, till her population were roused to resistance by a system of perfidy and aggression, on the part of the French ruler, unexampled in the history of the world.

Not satisfied with having at his disposal the resources of the Spanish monarchy, Bonaparte meditated the total subjugation of the kingdom, and the conferring its sovereignty as a conquered province upon one of his own family. Having gained over Godoy to his interests, and sown dissensions among the royal family, he decoyed them, under the mask of friendship, to Bayonne, and there by threats compelled them to sign a renunciation of their rights to the crown of Spain and the Indies, and placed his brother Joseph upon the throne of that kingdom. This plan of oppression and aggrandisement, with the subsequent transactions of the Peninsula until the capture of Cividad Rodrigo by Lord Wellington in 1812, are circumstantially detailed in our article BRITAIN.

It will be seen from our last reference that the campaign of 1812, commenced on the east of the Peninsula, very unfavourably for the Spanish cause. The army under General Blake was annihilated by Suchet, who reduced almost the whole of Catalonia and Valencia. On the western frontier, however, the capture of Cividad Rodrigo secured the safety of Portugal, and at the same time opened a way into the centre of Spain. While Lord Wellington was prosecuting the siege of this city General Hill advanced upon Merida, which was evacuated on his approach, and by this movement the country between the Tagus and the Guadiana was completely cleared of the enemy, and the forces of Marmont and Soult effectually separated. Upon the fall of Cividad Rodrigo, Lord Wellington moved the greater part of his army towards Badajos, which, in the preceding year, had been surrendered, after a feeble defence by the Spaniards. This fortress was considered as an object of primary importance to his future operations, and he resolved to push the siege with the greatest vigour. By the middle of March the place was completely invested, and on the 29th, a sortee of the garrison was repelled with considerable loss. On the 31st the British fire opened from 26 pieces of cannon, which were strengthened by six more on the 4th of April; and by the 6th, three practicable breaches were effected, which determined his lordship to an immediate assault. About ten o'clock in the evening, the troops destined for this arduous duty advanced in four divisions. That, under Major General Picton, carried the castle of Badajos by escalade, and Major Wilson with 200 men established himself in the ravelin of St. Roque. The false attack committed to Lieutenant-General Leith, being converted into a real one, was completely successful. The division led by the Honourable Major-General Colville, and Lieutenant-Colonel Bernard, encountered more serious opposition. They advanced to the assault of the breaches with the utmost intrepidity, but such were the impediments raised by the enemy, that after repeated attempts, and the loss of many brave men, they were unable to accomplish their object. As the town and castle, however, were in possession of the British, all resistance ceased; and the French governor, who had retired with his staff into fort St. Christoval, surrendered at day-light in the following morning. This brilliant exploit was accompanied with the immense loss of 1,035 killed, and 3,789 wounded. During these operations of the allied army, Soult was rapidly advancing to the relief of Badajos; and Marmont had penetrated into the interior of Portugal, after an unsuccessful attempt upon Cividad Rodrigo. As soon, however, as they learned the result of the siege, they both retraced their steps, the one towards Salamanca, and the other towards Seville.

The British commander now meditated more extended operations; and, in order to prevent any communication between the French generals, he detached General Hill to destroy the bridge of Almarez, which formed the only passage below Toledo, by which a large army could cross the Tagus. This bridge was protected by two strong forts erected on each side of the river, and defended by 18 pieces of artillery; but this gallant officer, after a fatiguing march, in which he was obliged to leave his artillery behind, carried the one on the left bank at the point of the bayonet; which struck such a panic into the garrison of the other, that they abandoned the fort and fled in the greatest confusion.

Every preparation being made for the advance of the allied army, it crossed the Agueda; and reached Salamanca on the 16th of June. Marmont had constructed a strong line of forts in the neighbourhood of this city, with which he kept up a close communication, but by a masterly manœuvre of Lord Wellington, he was compelled to abandon them to their fate. Their reduction, however, proved a work of no small difficulty, and it was the end of June before the army was again in motion. The enemy had taken up a strong position on the Douro, which it was considered imprudent to attack. Lord Wellington, therefore, instead of advancing upon Valladolid, threatened the Spanish capital, but Marmont having received reinforcements from the army in the north, and thus become superior in numbers, by a skilful movement, turned the flanks of the allies, and re-established his own communication with Madrid. This was followed by a series of dexterous manœuvres in attempting to cut off the retreat of the British army, which, however, were met by evolutions not less brilliant on the part of Lord Wellington, who was anxiously waiting for an opportunity to come to an engagement. The over extension and weakening of the enemy's line pointed out the favourable moment, when General Pakenham commenced a furious assault on the flank of the French left, which was at the same time attacked in front by General Bradford's brigade, and the cavalry under Sir Stapleton Cotton, and, though well posted and defended by cannon, was completely overthrown. General Pack made a gallant attack upon the enemy's centre, on the Arapiles, which, however, did not succeed until supported on the right by General Leith, when they were driven from the hill with precipitation. The other wing of the enemy, reinforced by the fugitives from the left, still showed a determination to resist, but, after a sharp attack upon its right and front, the rout became general, and they were saved from destruction only by the darkness of the night. At daybreak the pursuit was renewed; and, coming up with the enemy's rear-guard, their cavalry was routed, and three battalions of infantry made prisoners. The fruits of this victory were eleven pieces of cannon, two eagles, six colours, and upwards of 7000 prisoners, which were bought by the British with the loss of 700 killed and above 4000 wounded. Marmont retreated with his broken army upon Burgos; and Joseph Bonaparte, who had been advancing with the army of the centre to join before the battle, was met by his flying squadrons, and retired to the capital. Lord Wellington, having left a force under General Paget to watch the motions of Marmont, proceeded to Madrid, which was immediately evacuated—the French retreating by Toledo and Aranjuez. The British troops entered on the 12th of August, and a French garrison, amounting to 2500 men, which had been left in the Retiro, surrendered prisoners of war.

The intelligence of the battle of Salamanca and the occupation of Madrid, determined Marshal Soult to withdraw the besieging army from before Cadiz, and to evacuate Andalusia, and, having joined his forces to those of Suchet and Joseph, to attempt the recovery of the Spanish capital. This movement enabled the allied forces under the Spanish General La Cruz and Col. Skerret, to advance upon Seville, which was taken by assault.

After remaining some time at Madrid, Lord Wellington advanced to the siege of Burgos, which was held by the enemy as the key of the north of Spain, and the castle of which they had rendered one of the strongest forts in the peninsula. He had been led to believe, from the magnificent promises of the Spanish government, that he would receive the support of the army of Galicia, which was represented as consisting of 30,000 troops, in the highest state of discipline and equipment, and led by officers of talent and experience; but discovered, to his great mortification, that this mighty army had dwindled into 10,000 raw levies, without equipments, and commanded by men who had yet to learn the rudiments of their profession. The rapidity of his march prevented the transportation of heavy artillery, which compelled him to abandon the ordinary method of attack, and to adopt the slower and more uncertain process of sapping the works. The fortifications on St. Michael's hill were successfully stormed, and in spite of the skilful and resolute defence of the garrison in the castle. the besiegers had established themselves within a hundred yards of the enemy's interior line. On the 11th of October a mine was sprung, when the breaches were instantly stormed, and a part of the British troops actually entered the works; but a heavy fire from the garrison compelled them to retire.

While the allies were engaged in these operations before Burgos, the beaten army of Marmont had been greatly reinforced under Souham, and was advancing to the relief of that important fortress; and at the same time Soult was hastening from the south for the purpose of forming a junction with the northern army. The intelligence of these movements determined Lord Wellington to raise the siege, and retire upon the Douro. Though pressed closely, and at different points by very superior numbers, he retreated in the finest order, without any other inconvenience than what arose from the badness of the roads, towards the frontiers of Portugal, where the troops were allowed to repose in their cantonments until the season of action again arrived.

At the opening of the campaign in 1813, the enemy occupied the centre of the peninsula, having their head quarters of the different armies at Madrid, Toledo, and Valladolid; while the line of the allies formed an extensive semicircle reaching from Galicia to the confines of Murcia and Valencia. Lord Wellington assembled his forces in the vicinity of Cividad Rodrigo, and having driven the French from Salamance, advanced upon the Douro, which he crossed with the main body of his army. He proceeded without opposition along the northern banks of that river to Valladolid, where the enemy had concentrated their armies. They did not, however, attempt to defend that city, or dispute the passage of the Pisuerga; but retreated at the approach of the allies without intermission, until they reached Burgos. Though occupying a strong position, and evincing a determination to stand, a charge of British cavalry turned both their flanks, and compelled them to withdraw and abandon that fortress, after destroying the works of the castle, which had cost them so great labour and expense in constructing. Lord Wellington, instead of following the route of the enemy, hastened to the Ebro, which he crossed on the 15th of June, and continued his March towards Vittoria, which the French had made their central depôt in the frontier provinces. Here he found the enemy strongly posted, and commanded by Joseph Bonaparte in person, having Marshal Jourdan as his major general. The allied army rested on the 20th, and on the following day, after a severe contest, obtained a most brilliant victory, driving the enemy from all his positions, and capturing 151 pieces of cannon, 415 waggons of ammunition, with all their baggage and stores, and a considerable number of prisoners. So complete was their defeat, that the enemy carried with them only one gun and one howitzer, and this solitary gun was afterwards captured. The fugitive army pursued its retreat, harassed at every point, until it crossed the Pyrenees, and the French were in a short time dislodged from all their posts in the north of Spain, except St. Sebastian and Pampluna, which it became necessary to reduce, before employing the allied army in more decisive operations.

Soult, who had been withdrawn from the Spanish war, to assist his master in Germany, was again appointed as the fittest person to restore the glory of the French arms in the Peninsula, and to relieve, if possible, the two principal strongholds which still acknowledged their dominion in that country. The beaten army, now stationed within the frontiers of France, having been greatly reinforced, and completely equipped, was joined on the 13th of July by the French marshal, who, when he assumed the command, boasted to his troops that he would drive the British beyond the Ebro, and celebrate the emperor's birth day in the town of Vittoria. The allied army occupied the passes of the Pyrenees, which afforded very strong positions, but the lofty chains of mountains which intervened, rendered the communication between the different divisions tedious and difficult. Soult, aware of the unfavourable situation of the allies in this respect, resolved to attack them separately; and, on the 24th, burst with an overwhelming force through the pass of Roncesvalles, which was defended by General Byng and Sir Lowry Cole, who maintained their post throughout the day, but found it necessary to retire in the night to the neighbourhood of Zubiri. In the afternoon of the same day, another division of the enemy attacked the position of Sir R. Hill, in the valley of Bastan, which was hardly contested for seven hours, when that officer, being apprised of the retreat of General Byng, by which his rear was threatened, fell back upon Irurita. Lord Wellington was not informed of these events till late in the following day, when he immediately adopted measures for concentrating his forces. Soult, on the 27th, arrived in sight of the walls of Pampluna, and after some severe fighting, by the 29th had occupied a formidable position in the mountains. The allies had also formed on a range of heights no less impregnable, but neither seemed willing to become the first aggressor. The enemy, however, trusting to the natural strength of his situation, withdrew a considerable body of troops from the front, with a view to strengthen his attack upon General Hill, when the British commander perceiving his line thus weakened, ordered Lord Dalhousie and General Picton to drive him from the heights on which his right and left rested, which being rapidly accomplished, the centre advanced to the attack and obliged him to abandon his position, which Lord Wellington in his despatches described as "the strongest and most difficult of access that he had ever seen occupied by troops." In his retreat he lost many prisoners and much baggage, and though he twice attempted to make a stand, he was at last compelled to retire within his own frontier.

While Lord Wellington was pursuing a brilliant career in the north, the operations of the allies on the eastern coast of Spain were attended with a less decisive result. The French held the numerous fortresses of Catalonia and Valencia, and Suchet with a large army occupied an advanced position at San Felippe on the line of the Xucar. The allies on the other hand, were stationed at Alicant under Sir John Murray, and consisted of several British and native regiments, which had been withdrawn from Sicily, and a considerable force collected from the neighbouring provinces, which had been organized in the Balearic islands under British officers: a Spanish army under General Elio also occupied the frontiers of Murcia. About the middle of April Sir John Murray advanced to Castella; and Elio, at the same time, took post at Villena. Suchet having driven back the Spanish force, pushed forward to Castella, where he encountered for the first time a British army; but he was met with such undaunted steadiness that he was repulsed with considerable loss, and retired with precipitation to his entrenched camp at San Felippe. The British general made no attempt to follow up his success; and his advance to Castella seems to have been intended chiefly to prevent Suchet from detaching any part of his force to the aid of the central army under Joseph Bonaparte. But when Lord Wellington moved from Salamanca, he directed General Murray to conduct an expedition of 1000 men by sea, to the attack of Tarragona, which it was supposed would induce Suchet to weaken his force in Valencia, and enable the Spanish generals to take possession of a great part, if not the whole of the open country in that province. This expedition having reached its destination, continued to prosecute the siege of Tarragona from the 3d to the 17th of July, when the approach of a superior force to its relief induced the British commander to embark his troops, leaving behind a considerable portion of his cannon and stores. The failure of this attempt, however, was not attended with any unfavourable results to the general cause. Lord William Bentinck having assumed the command, ordered the troops back to Alicant, and having there joined the Spanish armies, continued to maintain a war of posts, and to occupy the forces of Suchet, until the third Spanish army was detached to co-operate with Lord Wellington on the frontiers of France, when the remainder of the troops were called to act entirely on the defensive.

St. Sebastian capitulated on the 8th of September after a most gallant defence, and a severe loss to the besiegers, which, with the fall of Pampluna on the 31st of October, enabled Lord Wellington to become the invader in his turn. The French had formed two successive lines of defence, which they had been diligently employed in fortifying ever since the battle of Vittoria; the one along the course of the Nivelle, and the other immediately in front of Bayonne. The first of these was stormed on the 10th of November; and though disputed from day light till sun-set, the allies succeeded in carrying all the positions on the enemy's left and centre; and, by establishing themselves in the rear of the strong positions occupied by their right, obliged them to evacuate these also during the night. Soult now fell back upon his entrenched camp before Bayonne, of which the left occupied the peninsula formed by the confluence of the Adour and the Nive, and the right and centre extended from the left bank of the Nive to the Adour below the town, defended in front by an impassable morass. This position was so fortified by nature and art as rendered it impregnable against any direct attack, and it was therefore determined by a movement to the right to threaten his rear and interrupt his communication with France. For this purpose General Hill crossed the Nive on the ninth of December, and having driven the enemy from the right bank of the river, moved with his right towards the Adour. Soult, aware of the result of these operations, if not immediately checked, made a most desperate attack upon the left of the allies under Sir John Hope, which, however, was repulsed in a most gallant style. A similar attempt on the 12th proving equally unsuccessful, Soult passed, during the night, a large force to the left, and attacked General Hill with great fury, but was driven back with immense loss, and compelled to retire within his entrenchments. By these operations the allies firmly established themselves between the Nive and the Adour, and thus accomplished the liberation of Spain.

CHAP. VII.—*Spain under the Cortes—Ferdinand returns and again establishes an absolute government.*

When Bonaparte had decoyed within his power the royal family of Spain, and had raised his brother Joseph to the throne of that kingdom, the junta of government, which had been appointed by Ferdinand before his departure from Madrid, basely betrayed his cause by acknowledging the usurper, and the inquisitor-general, the highest religious authority in Spain, lent his aid in accomplishing the degradation and destruction of his country. The nation in general, however, were actuated by more patriotic feelings, and, as if by one instantaneous impulse, raised the standard of independence. Juntas were formed in every province, who adopted measures for the general defence, and for the recovery of the country; and in this struggle the lead was taken by the supreme junta of Seville. Many of the members of these bodies, however, though zealously devoted to the cause of their country, were still too much attached to its old abominations. Commissions and commands were bestowed not upon those who deserved them most, but upon their own friends and dependants; and even after the bitter experience of twelve months of disasters, no effectual measures were taken for improving the discipline of their armies, or supplying them in the field. The establishment of a central junta brought no remedy to those evils; and though among the members of this provincial government we find the names of the venerable Florida Blanca and the accomplished Jovellanos, yet they enjoyed neither the confidence nor the respect of the people. Their proclamations indeed were distinguished by a boldness and an energy worthy of the cause in which they were engaged; but never was language so belied by deeds. Their incapacity was so apparent, that a regency was loudly demanded, to whom they transferred all their authority, providing that it should be retained only until the meeting of the cortes. But no sooner were the central junta denuded of their power, than they became the victims of popular indignation. They were accused of having peculated the public money; and the regency, though convinced how false the charge was with respect to many of them, yet, yielding to the general clamour, and perhaps courting popularity, included them all in a general censure, by seizing their papers, and registering their effects. Even Jovellanos, whose patriotism and unsullied honour had never been suspected, was ordered to retire to his own province of Asturias, and placed under the inspection of the magistrates. The last act of the central junta consigned to the regency the charge of assembling the general and extraordinary cortes, according to a plan of representation which they had formed after much labour and research; but the meeting of this body was delayed for some time, and it was not until the month of June 1810 that a decree was issued ordering the elections to be completed with all possible speed. In this decree, however, the regency departed from the plan approved of by the junta, and convoked only one house. The privileged orders, the nobles and clergy, were not summoned at all, either to meet apart, or with the third estate, and were thus excluded entirely from the national representation.

The cortes commenced their proceedings on the 24th of September, and their first acts were to declare their own sovereignty, and to demand an acknowledgment of it from all the authorities, civil, military, or ecclesiastical, who were bound by oath to obey the decrees, laws, and constitution of the cortes. Their conduct, however, on this occasion, was marked with great precipitancy and intolerance. Almost at the instant that they decreed the separation of the legislative, judicial, and executive authorities, they confounded them in their own practice. Those who hesitated or refused to take the prescribed oath from conscientious scruples, as inconsistent with the fidelity which they had sworn to Ferdinand, were summarily punished with imprisonment or banishment, among whom were the bishop of Orense and the marquis del Palacio. Instead of infusing into the government, which continued to be held by a regency, that energy which the crisis required, they weakened and embarrassed its exertions by continually intermeddling with it; and, instead of directing their own attention to such measures as were necessary for the deliverance and security of the kingdom, they consumed their sittings in metaphysical discussions, and in framing a new constitution, a work which might well have been delayed to a fitter season.

This constitution was promulgated in 1812, and greatly resembled the French constitution of 1791. It was violently opposed in many parts of the kingdom; and even its fundamental doctrine, the sovereignty of the people, did not meet with that cordial reception from the nation which was anticipated. The sudden overthrow of the old system, and the extreme change from an absolute monarchy to a pure democracy, produced such revulsion of feeling in the hearts of many, as caused them to pause in the career which they had so gloriously begun. That burst of popular enthusiasm which arose in the peninsula, and was heard throughout Europe, was not the offspring of revolutionary principles, or even of discontent with their government, but it sprung from hatred of the usurper, and in defence of their rights, as an independent nation. The people had hailed the accession of Ferdinand to the throne, as releasing them from the tyranny of Godoy, who was held in almost universal detestation; and they still regarded him in adversity as their lawful and beloved monarch, whose return was the great object of all their exertions. Had the cortes then, as a provisional government, confined their attention to the administration of the affairs of the kingdom, and to the gradual adoption of measures for reforming the more glaring abuses of the old system, they would have carried with them the majority of the Spanish nation, and would have ensured at length a complete and thorough renovation of the government. But when they showed by their acts such a direct disregard of the feelings and prejudices of the people, invading, nay annihilating the rights of that prince, in whose behalf they had given such demonstrations of allegiance and affection, the nerve of patriotism was unstrung, and the national enthusiasm evaporated in a heartless cause. Not that their hatred of the usurper was lessened, but they had lost all confidence in their rulers; and hence that apathy exhibited by the majority of the Spaniards, and which was so much complained of by the allies at an advanced period of the war. Many of the better informed classes, though aware of the necessity of some reform, and perhaps considering this a favourable opportunity for making such alterations in the government as the circumstances of the country required, beheld with pain the conduct of the cortes, being convinced that their countrymen were totally unprepared for such an order of things, and that the adoption of the new constitution would tend only to retard the progress of rational liberty. Some even regarded the assembly itself as unconstitutional, and as resembling the ancient cortes only in name. It bore, indeed, some resemblance to the cortes of Charles V., after he had removed from its sittings the nobles and clergy, and which he then dissipated with a breath. These classes, whose interests and privileges were thus invaded, possessed great influence among the people: and their defection and opposition carried with them the great body of the nation. The promulgation of the new constitution consequently spread dissatisfaction and disunion throughout the peninsula; and so apprehensive were the new authorities of a popular commotion, that they refused arms to the inhabitants of Galicia, who had applied for them to defend their own province, at that time menaced by the enemy.

From this period, the exertions of the peasantry ceased, and all attempts to organize a popular force proved ineffectual. A plan for incorporating Spanish recruits in the allied army, under British officers, also failed; and had it not been for the desultory operations of the guerillas, who, under Empecinado, Mina, and other patriotic chiefs, continued to maintain an unwearied and destructive warfare against the invaders, the national cause was in danger of being forgotten amidst internal dissensions. It seemed to occupy but a small share of the attention or exertions of the Spanish rulers, and the majority of the people regarded with calm indifference the deliverance which Britain was accomplishing for their country. The British army, it is true, was every where received with *vivas*, but it was now no uncommon thing for Spanish patriotism to evaporate in these noisy ebullitions; and had it not been for the support of the British government, and the gallantry of her troops, Spain might have been at this moment an appendage of France. The unhappy division of the nation into constitutionalists and royalists, or, as they were afterwards called, *liberals* and *serviles*, completely neutralized the exertions of the people; and while the cortes were intent upon perfecting the new constitution, and, among many injudicious and even tyrannical acts, had passed some very important and beneficial measures, the press, and even the pulpits in many parts of the country, were employed in condemning their decrees, and in convincing the people that all exertions in favour of such a government, was rebelling against the authority of their lawful monarch.

Amidst these contentions, Ferdinand was restored to his kingdom. Of the two factions, the preponderance of talent and patriotism was on the side of the constitutionalists, but the royalists possessed greater wealth and influence; and it might easily have been foreseen which cause a prince of Ferdinand's temper and education would most readily espouse. Before his return, he had sworn to maintain the constitution; but he no sooner found himself surrounded by the nobles and clergy, whose rights and privileges that constitution had in a great measure swept away, than his royal oath yielded to the ambitious wish of reigning the absolute sovereign of Spain. He immediately annulled the constitution; and, in order to soothe its adherents, promised to convoke immediately the real cortes, and, with their aid, to frame a new system of government. But having escaped from the trammels of the constitution, his promise was forgotten; and seizing the reins of absolute power, he established in all their deformity the abominations of the old government. His will again became the law; and supported by a cabal of crafty and interested zealots, he stalked forth as the cruel persecutor of all who had in any degree lent their aid in accomplishing his own restoration, and the independence of their country. Sentences of imprisonment, exile, or personal servitude, were passed upon all the deputies of the cortes who had shown any zeal in the cause of freedom. Many distinguished leaders in the Spanish armies met with similar treatment, while others withdrew from persecution, by seeking an asylum in foreign countries. The yoke of despotism, however, was not borne without impatience. Occasional irruptions showed that the flame of liberty might be smothered, but was not extinguished. An attempt of Porlier at Corunna to accomplish a revolution upon the principles of the oppressed liberals, was followed by others in Valencia, Catalonia, and Galicia, but were all attended with similar results, and equally disastrous to their promoters. The unfortunate issue of these designs checked for a time the spirit of opposition, and Spain seemed to resign herself to her fate, presenting to a superficial observer an aspect of outward tranquillity, and quiet submission to the yoke of Ferdinand. The government reverted to its old principles, and if the term *absolute* can be applied to any monarch, the king of Spain at this period well deserved the appellation. The inquisition was restored with its ancient plenitude of authority; and among its first acts were, the publication of a long list of prohibited works, and a decree that all prints and pictures, as well as books, should be subjected to its previous censorship. One redeeming act of this government, however, which was passed in 1817, deserves our highest commendation. This was the abolition of the slave-trade, which, with respect to the coasts north of the line, was to be immediately enforced, and on those south of the line, the prohibition was to take place on the 30th of May 1820; and all who controverted this edict, were subjected to severe penalties.

The ministers of Ferdinand, however despotic and successful in repressing all attempts at insurrection, held no enviable situation. Many subjects of great difficulty called for their attention and exertions. The deficiency of the revenue to meet the current expenditure, the low state of industry and commerce, and the insurrections in the colonies, required a mind of no ordinary kind to remedy and control. These evils acted upon one another in such a way, as almost to preclude the possibility of relief. The state of the colonies produced a stagnation of commerce, by depriving it of that immense transit, upon which it had for many centuries almost entirely depended; this decay of trade produced a corresponding falling off in the ordinary revenue; and this again deprived government of the means of supporting the royal cause in South America. Under all these embarrassments, however, attempts were made to restore order and stability to the finances. A papal bull was obtained for the appropriation of a tenth part of the income of all ecclesiastics, which was to continue for six years; and for the present exigencies of the kingdom, proposals were issued for raising a loan of sixty millions of reals. But such was the low state of public credit, that although eight per cent. interest, and the guarantee of the war taxes for future payment were offered, few of the capitalists came forward, and the government was compelled to have recourse to a forced loan, to which foreign merchants residing in the sea-port towns were obliged to subscribe. This supply enabled ministers to proceed with activity in fitting out an expedition at Cadiz for America, which had been long in preparation, and which the merchants of that city had incessantly called for, as the only hope of restoring their ancient prosperity. But the troops collected for the purpose were very averse to such a service, and their repugnance to embark was well known. A plot was consequently formed by several of the officers of the expedition, supported by some of the most distinguished citizens of Cadiz, not merely to escape from a disagreeable service, but to overthrow the government, and to restore the constitution of the Cortes. The accomplishment of their object, however, was for a time defeated by the treachery of the Conde d'Abisbal, commander-in-chief of the expedition, who, being informed of the existence of a conspiracy, pretended to join heartily in the enterprise, and promised to promote it with all his influence. Having by these means become acquainted with the views of its promoters, he adopted the most decisive measures for its suppression. He assembled the garrison of Cadiz, amounting to about 6,000 men, marched to the camp at Santé Maria, where the plot had originated, and arrested above a hundred of the officers. He then dispersed several of the refractory regiments throughout the interior of Andalusia, and having appointed new officers to the remainder, embarked them for America. This act of dissimulation and treachery did not meet with the expected reward. Abisbal was superseded in the command of the expedition, which was given to the Conde de Calderon; and while his measures delayed the open expression of hostility, they aggravated the evil, by rendering the conspirators more cautious and determined. Aware of the prevailing discontent among the troops, the utmost exertions were made by government for the departure of the expedition; but when every preparation was completed, and the fleet in readiness, the conspiracy exploded, and gave a new aspect to the affairs of this unhappy kingdom.

Quiroga, a lieutenant-colonel, and one of the officers put under arrest by Abisbal, having concerted with Riego and other officers the plan of the insurrection, they fixed upon the first of January as the decisive day, when Riego burst into the town of Arcos, made prisoners of Calderon and all his staff, and proclaimed the constitution. On the same day Quiroga, having made his escape, joined his battalion at Alcala, and, surprising the garrison of San Fernando, incorporatd the troops with his own. He was then joined by Riego, and their united forces, amounting to more than 6,000 men, were immediately organized under the title of "the constitutional army." An address in the name of the army was then presented to the king, in which, after enumerating the evils which the brave defenders of their country had suffered from the measures of his government, they declared "that their sole object was to restore the constitution; and that to have it recognized that the nation, legitimately represented, has solely the right of giving herself laws, excited in them the purest ardour, and taught them to speak in accents of the warmest enthusiasm." At the same time Quiroga issued an address to the Spanish people, reminding them of the ancient glory and liberty of the nation, of its heroic resistance against the usurpation of Bonaparte, of the recompense which it had met with, and the miseries which had been the consequence: and calling upon them, therefore, "to co-operate in the glorious effort now made to restore to them the rights of which they had been deprived."

Shut up within the narrow boundaries of the Isla, and surrounded by 15,000 royalist troops under General Freyre, the patriots had no apparent means of extending their operations. Weeks elapsed in this stationary state, and their situation was becoming insensibly worse. The enthusiasm excited by their first success was gradually evaporating. Their resources and supplies were cut off, and little hope of deliverance remained, unless some effort could be made to rouse the country in their favour. In these circumstances, Riego, whose bold and adventurous spirit prompted him to undertake whatever was difficult and hazardous, suggested the romantic idea of marching at the head of a flying column to scatter the seeds of liberty in the provinces; while the rest of the army should maintain its position in the Isla. Having selected a band of 1500 men, he set forward on this daring enterprise. In many of the cities he was received with the warmest demonstrations of joy; but, seeing the patriotic cause supported by so small a force, none of the inhabitants were hardy enough to join its standard. His route was no sooner known than general O'Donnell was sent in pursuit with a considerable body of royalists. With this superior force Riego had constantly to contend, and, from the want of necessaries, always at a disadvantage. Pursued from post to post, and daily thinned by fatigue and repeated skirmishes, this little band presented in their progress a series of adventures and privations of which history offers few examples. Driven to seek for safety in the heights of the Sierra Morena, which could be reached only by the bridge of Cordova, Riego formed the daring resolution of marching the remnant of his column through that large city. As they passed through the streets barefooted, badly clothed, and chanting the patriotic hymn, the inhabitants, assembling in crowds, viewed them with wonder and admiration. They then hastened towards the mountains, but were overtaken by the royal army and suffered considerable loss. Reduced at last to 300 men, destitute of every thing, closely pressed, and hopeless of success, they were compelled to disperse, and each individual to seek safety for himself. "Such," says San Miguel, "was the fate of a column, worthy by its patriotism and valour of the most brilliant triumphs. Where so many concurrent circumstances combined against us, it was morally impossible for the result to be different. Fanaticism on the part of an enemy always more than triple our numbers; dismay and timidity in the well affected: pusillanimity and weakness in those who abandoned us in the hour of danger; the violation of promises by those who had engaged in the cause; unheard of labour and fatigue in such rapid torrents, and marches night and day through a mountainous country intersected by ravines,—all these circumstances combined must have disheartened the bravest troops. Wherever the column of patriot soldiers passed, the people applauded them, gave them provisions, effects and money; but no one joined them; at their departure they wished them success, and then proceeded to prepare lodgings for the troops that pursued them."

Quiroga still maintained a defensive attitude at San Fernando, and repulsed every attack of the enemy; but insulated from the rest of Spain, and enclosed on all sides by superior forces, the constitutional cause seemed to all appearance fast hastening to a close. The column of Riego, however, though annihilated, had accomplished its object. The flame of patriotism was excited in the places through which it had passed, and had extended to the remotest parts of the kingdom. The cry of "the constitution" was in a short time raised in Galicia, Navarre, and other provinces, with a demonstration of support which could not be resisted. The government made an imperfect attempt at reconciliation; but Madrid, which had been long secretly agitated, declared for the constitution. As a last resource, an extraordinary gazette was published on the 7th of March for convoking the Cortes; but this concession came too late. The whole population of Madrid tumultuously assembled, tore down the placards, and set up the constitutional stone, demanding, with loud cries, the constitution of 1812. The king was compelled to yield, and to submit to the degrading humiliation of restoring a constitution which it had been the first act of his reign to dissolve with every mark of reprobation, and to condemn to dungeons and to exile all who had been concerned in framing and upholding it. A decree was consequently issued by the king, in which he stated that, "as the general will of the people had been pronounced, he resolved to swear to the constitution promulgated by the general and extraordinary Cortes in the year 1812."

This revolution occasioned universal rejoicings among the friends of liberty. The dungeons gave up the tenants, who for so many years had been immured within their cells; the inquisition was suppressed by a royal decree; and the liberty of the press established on the same footing as by the former Cortes. The general harmony, however, was interrupted by an unfortunate collison between the military and the inhabitants of Cadiz, which produced very dismal consequences, General Freyre, who had steadily supported the royal cause, suddenly formed the resolution of proclaiming the constitution in Cadiz, and invited the chiefs of the national army to be present on the occasion. Quiroga, suspecting treachery, declined attending himself, but sent a deputation to represent the patriots in the approaching spectacle. After a night of joyful preparaton, Cadiz exhibited, on the morning of the 10th of March, a scene of indescribable animation. The deputies from the Isla were received with triumph; and the assembled multitude, arrayed in their festal dresses, waited only the arrival of General Freyre to begin the ceremony; when, on a sudden, the troops commenced firing on the populace, who, dispersing in all directions, were pursued and butchered wherever they were met. Even the houses afforded no protection to the wretched inhabitants; and Cadiz was for several hours like a city given up to pillage. In this inhuman massacre four hundred and sixty were killed and upwards of a thousand wounded; but its authors were never brought to punishment. Strong suspicions were excited against Valdes, the governor of the city, and Freyre was not without his share; but after a long investigation into this unhappy affair, its origin was never fully ascertained.

The elections for the approaching Cortes were completed without any disturbance, and were decidedly favourable to the liberal party. On the 6th of July, the king, attended by the queen, the royal family, and his ministers, opened the assembly, and, after renewing his oath of fidelity, strongly expressed his attachment to, and his determination to support the constitution. "At length," said he, "has come the day, the object of my ardent wishes, when I see myself surrounded by the representatives of the heroic and generous Spanish nation, and when a solemn oath identifies my interests and those of my family with the interests of my people. It is to the establishment and the entire and inviolable maintenance of the constitution, that I will consecrate the powers which this same constitution assigns to the royal authority; in it I will concentrate my power, my happiness, and my glory." After voting an address in reply to the king's speech, the Cortes received from the different ministers a view of the state of their respective departments. Of these the most important was that of finance, which detailed a deficiency of nearly two millions sterling, which it was proposed should be relieved by a loan of 200,000,000 reals. They then proceeded to the consideration of some permanent reforms in the political system; but here, throwing aside the lessons of experience which might have taught them that the constitution of 1812, without some considerable modifications, was adapted neither to the wants nor the wishes of the great majority of the people, they persisted in a series of measures calculated to excite the hostility of the nobles and clergy, and through them the great body of the peasantry. By abolishing the system of *maiorats* or entails, a severe blow was given to the family pride of the Spanish Grandees, which, added to their exclusion from the supreme legislature of their country, completely alienated them from the government; and by the suppression of the religious orders, and declaring their property national, thus reducing to a state of comparative beggary a numerous body who had always held a great sway over the public mind, and also throwing into a state of absolute destitution those swarms of mendicants who had been accustomed to receive supplies at the convent gates, they raised up a host of foes who could not but feel the bitterest enmity against the authors of their degradation and misery, and would be ever ready to join the ranks of the disaffected, and to disturb the tranquillity of the kingdom. If these proceedings, however wise in themselves, may be considered, in the present circumstances of the country, and from the time and manner of their execution, premature and precipitate, their regulations respecting trade were radically unwise and ruinous. Instead of those liberal views which were recommended in the writings of their most eminent economists, they adopted a system of commercial intercourse, the leading principle of which was, a complete exclusion of whatever Spain could produce within her own territory. This not only increased her financial embarrassments, but gave rise to an extensive contraband trade, which induced tumultuous and irregular habits among the people, and which had always been one of the greatest scourges of Spain. Their arrangements, however, for public instruction were of the most enlightened description, and evinced a laudable anxiety for the education of the people. Three gradations of schools were to be established throughout the kingdom, the first for elementary instruction, of which there was to be one for every five hundred families; the second for those destined for public employments; and the third for special and profound studies.

But while the Cortes were busily employed in these and other important discussions, and fixing the great outlines of the constitution, the nation in general was agitated by the most violent commotions. The king had given a reluctant sanction to the law for the suppression of the monastic orders; and the execution of it was in many places tumultuously opposed. The ejected monks every where called the peasantry to arms in defence of the throne and the altar, which they said were trampled under foot by the constitutional system. Assuming the form of guerillas, they were with difficulty reached by the regular troops, and when dispersed in one quarter immediately reappeared in another. On the other hand, the ultra-liberal clubs in the large cities, outraged and alarmed at these hostile movements, branded the government with want of energy, and even denounced the highest persons in the state as secretly encouraging them. Vinuesa, the king's chaplain, was openly accused of plotting the overthrow of the constitution; and when his majesty appeared in public, the crowd along with their acclamations of "Live the constitutional king," loudly demanded the death of Vinuesa, the disbanding of his guards, and the dismissal of such ministers as they considered not sufficiently devoted to the new system. These insults were so often reiterated, that some of the king's guards, determined to be no longer tame spectators of such treatment, charged the multitude sword in hand, by which several of the populace were wounded. This excited a dreadful ferment, and a general cry was raised for dissolving the regiment. The ministers so far yielded that the guards were superseded by another corps in attending upon the king's person.

Amidst these commotions, the Cortes was opened on the 1st of March by the king, who, in the conclusion of his speech, complained of the indignities which had been offered to his person, and broadly stated that "these insults would not have been repeated if the executive power had displayed all the energy which the constitution prescribes and the Cortes desires. The want of firmness, and the little activity of many of the authorities, have given room to the renewal of such excesses, and, should they continue, it will not be astonishing if the Spanish nation finds itself enveloped in numberless evils and misfortunes." The same evening that these complaints were uttered, all the ministers but one received their dismissal. This measure excited an extraordinary emotion among the liberal circles. It was considered a direct blow against the constitution: and so strong was the expression of public opinion, that the king did not venture to appoint their successors without requesting the advice of the Cortes. This assembly, however, declined interfering with the royal prerogative, but recommended that his majesty's confidence should be given only to those who had given decided proofs of their adherence to the constitutional system. A ministry was at length formed, which, in its composition, embraced both parties, and consequently gave satisfaction to neither. From this period the king showed evident symptoms of aversion to the ruling party in the Cortes, and they also had little confidence in his declarations of attachment to the constitution.

The attention of the Cortes was now strongly drawn to the internal security of the kingdom. The report of the committee on this subject stated the existence of a combination of plots for the overthrow of the constitution, all directed by a supreme junta. This was corroborated by the discovery of a document, in the hand-writing of Vinuesa, detailing a scheme for the re-establishment of the old government, which produced a strong sensation among the people. Vinuesa, whose trial for treason had been in progress, was soon after condemned to ten years close confinement in the galleys. A punishment so inadequate to the offence raised the indignation of the populace, who, rushing in a body towards the prison, and in spite of the guards, burst open the doors, and executed that terrible sentence which they judged due upon the unfortunate chaplain.

Strong guerilla parties headed by the monks, continued to disturb the provinces; and though repeatedly routed by Lopes Banos, an original and zealous champion of the revolution, they as often rallied, and were reinforced by the peasantry, who flocked in crowds to their standard. Severe decrees were passed for the suppression of these insurrections. All who were found engaged in them were to be tried by a council of war, and executed in forty-eight hours; and every Spaniard who propagated opinions tending to the overthrow of the constitution, was to be punished with fines and banishment.

The fermentation of parties was daily rising higher and higher. Petitions were poured in from all quarters for the dismissal of ministers; but they, determined to face the storm, endeavoured, by a course of vigorous measures, to overawe the hostile factions. They resolved that all the high commands should be filled only by persons devoted to their interest; and consequently they superseded the commandants of Cadiz and Seville. These cities, deeply embued with revolutionary principles, refused to receive the new governors, and addressed representations to the Cortes, justifying their rejection of chiefs sent by a ministry whom they had every reason to suspect. The command of the Cortes to submit was met by fresh representations, which called forth the just indignation of that body, who characterized such conduct as decidedly seditious and tending to rebellion. These cities, however, still continued refractory, and gave no signs of submission.

While these disputes were threatening the very existence of regular government, a contagious distemper of the most virulent nature broke out at Barcelona, and withdrew for a time the public attention from political dissensions. It continued to rage for upwards of two months, and is supposed to have carried off 20,000 of the inhabitants of Barcelona, and a proportional number in the neighbouring cities. It was under the pretext of guarding against the introduction of this pestilence, that the French government established an army on the frontiers, under the title of "the sanctary cordon," which afforded encouragement and even protection to the royalist guerillas, or, as they were now called, "the army of the faith." These insurgents were daily gaining strength, particularly in Navarre and the northern provinces. The great mass of the peasantry favoured their cause; and their bands were increased by many of the lower ranks from the cities, and by all who were connected with the Church. Ample funds were mysteriously supplied for their support. Pay, equipments, and even high bounties were given to all who joined their standard; and the soldiers of the faith were furnished with every necessary, when the regular troops drew neither pay nor subsistence except by forced contributions. They continued for a time to overrun the open country; but their force was at length broken by Lopes Banos, and was compelled to seek refuge in France, or to wander in detached bands amidst the most inaccessible mountains.

The king still retained his ministers, in spite of the representations of the Cortes; and the cities still resisted their authority. The dismissal of the one, however, was immediately followed by the submission of the other, who opened their gates to the governors, appointed by the king. A new ministry was formed under Martinez de la Rosa, who soon became equally unpopular with their predecessors. A proposition, introduced by them into the Cortes, for repressing the licentiousness of the press, and subjecting the patriotic clubs to a close surveillance, was passed by a great majority, in consequence of which the most violent of the clubs were shut up, and a strict police enforced in Madrid and the other great cities. But this seeming tranquillity was of short duration. Insurrectionary movements became general throughout Catalonia, Aragon, and Navarre. The armies of the faith under the Trappist and other leaders, were soon masters of the whole open country in these provinces. They had taken Cervera, surprised Mequinenza, and carried by a midnight assault the strong fortress of Seo d'Urgel, which, from its situation and inaccessible position in the mountains, afforded them a sure retreat in the greatest exigencies, and kept open their communication with France. They at one time had entered Tarragona, and, though driven out by general Haro, had gained the outworks of that important place, and kept it closely blockaded.

These events called for the most rigorous measures on the part of the Cortes. Servile principles were evidently spreading among the people; and, as the constitution could only be maintained by keeping on foot an overwhelming force, orders were issued for increasing the army to 63,000 men. The state of affairs, however, was rendered more critical by the well-grounded suspicion that the king himself encouraged the malcontents, and waited only a favourable opportunity openly to join them. This was confirmed by his conduct towards his favourite guards, whom he supported in their rebellion against the constituted authorities; and even declared that, after repeated insults towards his person, and the refusal of all means of protection, the constitutional compact was dissolved, and he was entitled to resume all his original rights. The rebellious guard, however, were at last reduced, and the king was under the necessity of allowing his unpopular advisers to retire. The formation of a new ministry was entrusted to Lopes Banos, which, of course, was strictly constitutional; and the most strenuous efforts were now made for suppressing the insurgents.

The royalists had, in the mean time, installed a regency at Urgel, consisting of the Marquis of Mata Florida, the Bishop of Tarragona, and the Baron d'Eroles, who issued a series of proclamations, declaring that the king was in a state of captivity, and that, till his deliverance, the only legitimate government of Spain resided in themselves. They called upon all true Spaniards to rise in the cause of the king and the church: and such was their influence that a levy en masse took place in the valley of Cerdagne, from which d'Eroles organized an army of 15,000 men, fully equipped and disciplined, leaving the remainder to act as guerillas. Against this formidable force, which held possession of all Catalonia, except the principal fortresses, which the national troops were with difficulty able to maintain, the whole power of the Spanish army was directed. The militia were entrusted with the garrison duty of the large towns, which rendered the regular troops disposable for active service; and all the regiments in the southern provinces were drawn towards Catalonia. The command in this arduous service was confided to the celebrated Mina, whose high reputation and particular experience in mountain warfare inspired the most sanguine hopes of a successful termination to the contest. Proceeding to Lerida, he detached a corps to observe Upper Aragon, and pushed forward towards Urgel, the focus of the insurrection. Cervera was evacuated at his approach, and Castelfolit yielded after a vigorous resistance. At Tora he encountered d'Eroles whose little army fought with the greatest fury, but were at last compelled to give way, and seek refuge among the mountains. D'Eroles, however, recovered and mustered a considerable force in front of Urgel. Here the decisive struggle was long and obstinately contested, but finally issued in the total rout and destruction of the army of the faith, whose scattered bands crowded towards the French frontier. The triumphant progress of Mina expelled the insurgents from Catalonia; but his career was marked with that ferocious rancour, which a civil war is so apt to engender, and which often confounds the innocent with the guilty. The "factions," as they were called, wherever met, were put to death without trial or any legal inquiry; and such villages as were known to have assisted the rebels, were sacked, demolished, or reduced to ashes. No quarter was given on either side, and all prisoners who fell into their hands were butchered in cold blood.

While Mina was employed in the mountains of Urgel, Bessieres and Ulman, two insurgent leaders, determined to make a dash at the capital, by which they expected to astound their enemies, and revive the courage of the royalists. Having collected a force of nearly 5000 men, they, by a rapid movement, reached Guadalaxara, before the authorities in Madrid were informed of their approach. The regular troops and militia in the neighbourhood were hastily assembled, and marched against the enemy, who, retiring, took up a position near Torvega. O'Daly, the constitutional general, commenced the attack, but his right wing, which was composed of raw militia, gave way, and he was obliged to retreat upon Guadalaxara, which he soon after abandoned to the enemy. In this crisis the Conde d'Abisbal was called to the command. Having obtained considerable reinforcements, he compelled the royalist army to fall back, which afterwards separated, Bessieres retiring upon the Ebro, and Ulman upon Valencia. The former was closely pursued and suffered considerable loss and dispersion; the latter, having been joined by numerous partizans in the neighbourhood of Segorbe, surprised the strong fortress of Murviedro, the ancient Saguntum, where he was enabled to maintain his ground, and to give a firm footing to the war in that province. In this critical state, Spain was now called to resist a more formidable enemy in defence of her national independence; but whose numbers and resources precluded all hope of a successful issue.

The affairs of Spain had formed a principal object of discussion at the congress of Verona; and the powers there assembled, with the exception of Great Britain, assumed the high authority of interfering with the internal arrangements of an independent kingdom, and of dictating terms humiliating and injurious to its present rulers. They demanded an immediate change in her institutions, and, in case of non-compliance, threatened her with all the horrors of war. Notes to this effect were delivered by their respective ambassadors at the court of Madrid, and were conceived in language calculated to excite the most hostile feelings, and a just indignation against their authors. They described the constitution of Spain as "an event the most deplorable,—the work of perjured soldiers—overturning the whole social system, and recalling times which made Europe tremble." The replies of ministers to these communications were by no means conciliating, but rather breathed too much a spirit of defiance and resentment. After representing, in answer to the French note, the constitution of 1812 as produced by the united will of Spain, and as recognised by all the powers now forming the congress at Verona, they add, "that the professions of France to contribute to the happiness of Spain cannot be held to be sincere until she dissolve her Pyrenean army, and repulse the factious enemies of Spain who take refuge in her territory." In a circular transmitted to the Spanish ambassadors resident at the other courts, and which was of a very concise nature, their notes are described as unworthy of an answer, and are characterized as a tissue of lies and calumnies; and they declare, in conclusion, that the Spanish nation will never admit the right of any power to interfere in her affairs. When these documents, with their answers, were laid before the Cortes, they excited a burst of noble and generous indignation: and the assembly, in their address to the throne, declare "their surprise and indignation at the strange calumnies, the manifest falsehoods, and the calumnious imputations contained in these documents, as vicious in their substance, as contrary in their form to the practices established among civilized nations, horribly injurious to the Spanish nation, to its most distinguished members, to its Cortes, to its government, to the throne even of your majesty, which, resting on the constitution, suffers not less from the attacks of which it is the object: lastly, to your sacred person, whose good faith and love for your subjects are attempted with an impious temerity, to be made the subject of doubt." The result of such language might easily have been anticipated. Louis XVIII. in his speech at the opening of the chambers, declared that the safety of France demanded the overthrow of the Spanish constitution. "Let Ferdinand VII. be free to give to his people *the institutions which they can hold only from him*, and which, in securing their repose, may dissipate the just inquietudes of France." That such iniquitous doctrine should emanate from the conclave of the Holy Alliance was not to be wondered at; but that it should be supported by any, except the most illiberal bigots of the most unmixed despotism, is humbling to human nature. These sentiments of the king were re-echoed by the representatives of the French nation. "To your majesty it belongs to deliberate; it is our part to concur with all our efforts in the generous enterprise of stifling anarchy to conquer only peace; of restoring liberty to a king of your blood; of securing the repose of Spain to confirm that of France; of delivering from the yoke of oppression a magnanimous people, who aided in breaking our chains, and which can *receive institutions conformable to its wishes and its manners only from its legitimate sovereign.*"

Six years of direful experience had taught Spain what she had to expect from the uncontrolled will of Ferdinand. He had subverted all her liberal institutions, and had consigned to dungeons and to exile some of the bravest and most enlightened of her sons. During that period she indeed enjoyed repose, but it was the repose of the grave, whose gloom no ray of light is permitted to penetrate,—a repose fatal to the industry, the intelligence, and the happiness of the people. Her only alternative therefore was war; and never was she in a worse condition to meet a foreign invader. Her finances in the most deplorable disorder—one half of her population in insurrection—her army weak and inefficient—her sovereign leagued with her enemies—and the invader powerful both in numbers and resources, and backed by all the kingdoms of continental Europe. The Spanish rulers were honest and earnest in the cause, but were miserably deficient in that wisdom and energy which such a crisis required. Their preparations were consequently far from being commensurate with the danger. Instead of putting under arms that portion of her people that were devoted to the constitutional cause, and which comprehended the inhabitants of all the great cities, the Cortes ordered the army to be raised merely to the war establishment of 120,000 men, and this order could only be imperfectly executed in consequence of the numerous districts in a state of insurrection, and the loose ties by which authority was held in the rest of the kingdom. But besides being greatly deficient in numbers, the Spanish army was greatly inferior in discipline and equipments to those veteran troops with which they were destined to contend. The Cortes, however, still held the language of confidence. "If the invading army invoke the God of St. Louis, we will invoke the God who protected the Spanish arms at Roncevaux and at St. Quentin; we will invoke the God of justice and of victory."

Great Britain, as the friend of both, endeavoured to avert the miseries of war, wisely forbearing, however, to commit herself in the cause; but her exertions were unavailing. The demands of France were unreasonable, and Spain refused all concession or approximation. Preparations for the campaign were carried on on both sides with the characteristic dispositions of the two nations: on the one side with energy and activity, on the other with sluggish apathy. While the Spanish ministers were slow but honest, the king was watching opportunities for paralyzing their exertions, and for subverting the constitution. Although he declared in his speech at the dissolution of the extraordinary Cortes, that "the law of national independence, and the necessity of preserving the constitution of 1812, were the replies which the nation would give to the antisocial principles contained in the speech of the King of France;" yet the same evening he dismissed his ministers, and obstinately opposed the removal of the seat of government from Madrid to a place of greater safety, and more remote from the frontier. This conduct, in the present circumstances of the nation, excited the popular indignation to such a height, that the palace was immediately surrounded by crowds of people, who loudly demanded the re-establishment of the dissolved ministry; and occasional cries were heard of "down with the tyrant—depose him—kill him." This intimidation had its effect. The ministers were restored, but their resignation was afterwards announced to the Cortes on the 2d of March, with this condition, however, that the new ministry should delay their operations till their predecessors had each read reports on the state of their respective departments. A warm debate ensued, in which it was openly stated, that a conspiracy was organized in the heart of the palace, and that the crisis required the Cortes to declare the physical incapacity of his majesty. The majority, however, agreed that in order to avert the evils which would follow an immediate dissolution of the ministry, they should delay hearing the reports till the removal of the seat of government had been effected: and thus, in virtue of the king's declaration, ministers would continue till that time in the exercise of their functions. The king, under various pretences, resisted his leaving Madrid, but it was at last pressed by the Cortes in such a way as left no room for choice, when he reluctantly yielded and set out for Seville on the 20th of March.

The entrance into the peninsula by the French army under the duke d'Angouleme was preceded by a proclamation, in which that prince professed himself to be the friend of Spain. "Born of the same blood with your kings, I can desire only your independence, your happiness, and your glory. The French are, and wish only to be your auxiliaries; your standards alone will float on your cities; the provinces traversed by our soldiers will be administered in the name of Ferdinand by Spanish authorities; the most severe discipline will be observed; all that shall be necessary for the service of the army will be paid with religious exactness." The defence of the peninsula was intrusted to the bravest and most experienced of its generals; with means indeed totally inadequate to the struggle, but what was worse, in some with hearts not earnest in the cause. Mina held the command in Catalonia; Ballasteros in Aragon, Valencia, and Murcia; Abisbal in the Castiles and all the centre of Spain; Morillo in the north; and Villacampa was employed in Andalusia to organize an army of reserve.

The French crossed the Bidassoa on the 7th of April, and reached Madrid on the 23d of May, without encountering any resistance, except at Logrono, where a sharp action was maintained with the vanguard. The troops and militia, stationed in the different towns, retired on the approach of the enemy. The strong fortresses of Pampluna and St. Sebastian answered the summons to surrender by a brisk sally; and as no immediate impression could be made upon them, they were subjected to a blockade; but Saragossa was evacuated by Ballasteros without striking a blow in its defence.

Everywhere upon the line of march the *serviles*, consisting chiefly of the priests and lowest classes, rose against their opponents, and maltreated and plundered all whom they suspected of liberal sentiments. Both factions bore a greater enmity to each other than to the foreign invaders; and the constitutionalists were often obliged to seek protection from the enemy against the infuriate excesses of their own countrymen. The arrival of the French was consequently hailed in many places as a deliverance from more serious evils. The duke, having installed a Spanish regency at Madrid for the general administration of the country, despatched two divisions under generals Bourmont and Bourdesoult to the south of Spain, with orders to advance upon Seville and Cadiz, the one by the way of Estremadura, and the other by that of La Mancha.

In the meantime the Cortes had commenced their sittings at Seville; but all their proceedings with respect to the defence of the country were carried on with their usual supineness and apathy. No symptom of national rising had yet appeared, and their only hope rested on the force actually under arms, which could not be depended upon for any protracted resistance. But the rapid advance of the French called upon them to consult for their own safety; and they determined to transfer the government to Cadiz. This was openly resisted by the king, who now expected that in a few days Seville would be in the hands of his friends, when he would be restored to absolute sovereignty. He was consequently declared to be in a state of moral incapacity for fulfilling his functions; and a provisional regency was appointed, who set out for Cadiz on the 12th of June, carrying with them the king, now openly and avowedly a prisoner. The constitutional cause, however, was rapidly declining; and its sunshine adherents were dropping fast into the ranks of the enemy. The Conde d'Abisbal had been driven from his command by his own army on account of his correspondence with the opposite party: the defection of Morillo hastened the subjugation of the northern provinces; and Ballasteros had concluded a convention, in which he agreed to acknowledge the regency appointed by the French. As a contrast, however, to these sad instances of weakness and treachery, the gallant Mina was maintaining a desultory and protracted war against a very superior force in the mountains of Catalonia; and the reduction of that province was as distant as at the commencement of the campaign.

The French armies reached Cadiz without any serious encounter, and during the whole of their advance, conducted themselves with great caution and moderation. Not so their faithful allies, who, urged by personal enmity and the hope of plunder, wished to commit every species of outrage against their political antagonists; and the attempts of the French officers to repress their hostility, occasioned such frequent disputes and dissensions as led at last to the decree of the duke at Andujar, which prohibited any arrest by Spanish authorities, without the consent of the French officer commanding in the district, and authorised this officer to set at liberty all those who had been arbitrarily arrested. The duke joined the army before Cadiz on the 16th of August, where was collected a force of 30,000 French troops, with a formidable train of artillery. An attempt at negotiation having failed, the French commenced their operations by storming the Trocadero, a small peninsula nearly opposite to Cadiz, and commanding the naval approaches to the city. The fall of this important post spread dismay and discouragement among the constitutionalists. The troops felt the impulse, and began to show symptoms of royalism; and the only body of men that could now be relied on was the militia, particularly that of Madrid. In these circumstances the Cortes would gladly have purchased peace, by consenting to modify the constitution; which, had it been done in time, might have saved Spain, but it was now too late. The duke d'Angouleme demanded the immediate liberation of Ferdinand, and declared that he could not consider him as free until he saw him in the midst of the French army. He at the same time expressed his confident expectation, that his majesty, on being restored to liberty, would grant a general amnesty, and convoke the ancient Cortes of the kingdom. The Spanish government, however, were not yet prepared for such unqualified submission; but they were also wanting in that heroic spirit of resistance which was requisite to throw a lustre around a sinking cause. The same weakness and infatuation which had been so conspicuous on the part of the constitutionalists in the progress of this most inglorious campaign, marked also its close; and it terminated by an unconditional surrender of their liberties and lives into the hands of an unfeeling and senseless despot.

Before his departure for the French camp, the oath-breaking Ferdinand promised a full and complete oblivion of all offences, and that, in the re-establishment of his government, some regard would be paid to the liberties of the nation; but, on the very day of his deliverance, he characterized the late revolution as "the most criminal treason, the most shameful baseness, and the most horrible wrong against his royal person." He soon after issued a succession of decrees, breathing the most unbounded fury against every one who was in any way connected with the constitutional system; and all who had been deputies to the Cortes, or had filled any office or function of government since March 1820, or who had even been in the ranks of the national militia, were prohibited from approaching within five leagues of his majesty on his way to Madrid, and during their whole lives, from coming within fifteen leagues of the capital.

The fall of Cadiz was soon after followed by the surrender of all the important fortresses in the kingdom. Mina, who held the command of the strong garrisons of Barcelona, Tarragona and Hostalrich, obtained an honourable capitulation; and the same terms were granted to Torrijos in Carthagena.

Ferdinand's arrival at Madrid was preceded by that of the Duke d'Angouleme, to whom the nation looked for some mitigation of his proscriptions; but whether that prince, who had repeatedly pledged himself that the restored government would act with lenity, and grant some form of a free constitution, found his advice neglected, or was unwilling to use his influence, no alleviating decree ever appeared. He spent only a few days with the king, and left him absolute master of Spain, with a French army ready to execute whatever purposes of vengeance his caprice or his tyranny might dictate.

Only one noble victim was in his power, who, it was resolved, should be immolated upon the altar of despotism; and this was the gallant and unfortunate Riego. Upon the first investment of Cadiz, he had been entrusted with the command at Malaga, and had been taken prisoner while again endeavouring, at the head of a flying column, to rouse the spirit of the provinces. After a mock trial he was condemned, and he died in a manner worthy of the glorious cause of which he was a martyr. The members of the Cortes, and of the former government, with the principal chiefs, lost no time in removing from their oppressed country; and Spain was daily thinned of the most intelligent and industrious of her population.

But while the presence of the French army prevented any effective reaction on the part of the constitutionalists, France made no secret of her disapprobation of the measures of Ferdinand, which were characterized by the most senseless severity; and when her remonstrances were disregarded, she threatened to withdraw her forces from Spain, and leave the absolute king to depend upon the loyalty and affection of his own people. This had the effect of producing some alleviating decrees; but they were so clogged with exceptions, that the exiles, deprived of all hope of mercy, were driven to despair. Several insurrections in different parts of Spain were the consequence, but they were all equally unsuccessful; and this fine kingdom, notwithstanding the superior intelligence of many of its inhabitants is fast sinking into a state of barbarism.

The finances of Spain are in the most deplorable condition. The great capitalists of Europe have refused every accommodation until the loans of the constitutional government be recognised; and the expenses of the army of occupation have fallen entirely upon France.

The sway of Ferdinand, however, has been considered even too mild by the servile and monkish faction; and a plot was formed for his dethronement, and the substitution of his brother Don Carlos. In this conspiracy many of the nobles and prelates were seriously implicated; and general Bessieres, its ostensible organ, who had raised the standard of revolt at Torrija, was taken and shot. Nearly at the same time two constitutionalists, Paul Iglesias, and the famous Empecinado, Don Juan Martin, were apprehended at Tariffa, and publicly executed. The serviles have now the complete ascendency in the councils of Spain; but its infatuated monarch is only preparing for himself and for his country new troubles and commotions. The bands of oppression are already stretched nearly to the utmost, and must sooner or later give way, when this unhappy kingdom may be again involved in all the miseries of revolutionary anarchy; and in the reaction of parties, the happiness and safety of its inhabitants may be sacrificed in the gratification of private ambition or revenge. PART II.—STATISTICS.

Chap. I.—*Boundaries and Extent—Progressive Geography—Modern Division—Mountains—Rivers—Canals—Climate—Natural History.*

Spain, a kingdom, famous both in ancient and modern history, forms, along with Portugal, an extensive peninsula in the south-western division of Europe; and is separated from the Continent by a chain of mountains, which furnish it either with an easy communication, or a formidable barrier. It lies between 43° 44′ and 35° 57′ north latitude; and 21° and 8° 20′ west longitude from Paris, making its greatest breadth from Cape Creus to Cape Finisterre, 219 leagues, and its greatest length from Cape Ortugal to Gibraltar, 195 leagues. It is bounded on the north and north-east by the Bay of Biscay and Pyrenees; on the south and south-east by the Mediterranean, the Straits of Gibraltar, and the Atlantic; and on the west by the Atlantic and Portugal.

This Peninsula was first divided by the Romans into *Hispania Citerior* and *Ulterior*, but was soon after known by the names of Lusitania, Boetica, and Tarraconensis. *Lusitania* formed the western part, and had its limits marked by the Douro on the north, and on the south by the Guadiana, including in its extent Portugal, Leon, and part of Estremadura. *Bœtica* was surrounded on three sides by the sea and the Guadiana, and had for its eastern boundary, a line drawn from Cazlona to Murgis on the Mediterranean. It extended from Badajos to Cape de Gatte, and contained modern Andalusia and part of Estremadura. All the other parts of Spain were comprehended under *Hispania Tarraconensis.* This division, however, underwent some alterations under the last Roman Emperors, and was totally changed after the invasion of the Visigoths. But it is from the conquest of this country by the Moors that we must date the modern division of Spain; and the origin of the different kingdoms and principalities, which were progressively formed from the middle of the 8th to the end of the 15th century.

The geographical division of Spain most commonly adopted in modern times, is limited to fourteen provinces, kingdoms, or lordships, all of which are governed by a captain-general, except Navarre, the governor of which has the title of viceroy. These are

Biscay,	Murcia,
Asturias,	Valencia,
Galicia,	Catalonia,
Leon,	Aragon,
Estremadura,	Navarre,
Andalusia,	Old Castile,
Granada,	New Castile.

As all these provinces, except Valencia, have been already particularly described in this work, we shall content ourselves merely with references to the above articles, and proceed to a general account of the kingdom.

"No country of Europe," says M. Humboldt "presents so singular a configuration as Spain. It is this extraordinary form which accounts for the aridity of the soil in the interior of the Castiles, the power of evaporation, the want of rivers, and that difference of temperature which is observable between Madrid and other towns situated in the same degree of latitude." The interior of the country is an elevated plain, gradually declining towards the south-west; and the table-land of the two Castiles exceed in height and extent any of the same kind of Europe, having its mean elevation 300 fathoms above the level of the ocean.

The Spanish mountains appear to be arranged in distinct chains; but they are, in fact, ramifications from one another, and though separated by considerable intervals, are all linked to the same stock. "The first chain that we perceive," says Laborde, "on leaving Cape Finisterre, stretches along the whole of the north of Spain, and joins the Pyrenees; in this are the sources of the Minho and Douro, which throw themselves into the Atlantic, and that of the Ebro, the course of which is towards the Mediterranean. These mountains, advancing towards the south-east, divide the streams which flow into the Ebro from those which augment the Douro. On one side, they form the outline of Aragon, and on the other, that of Old Castile. They advance thus as far as Cuença and Molina, the names of which they take; and soon after give rise to the Tagus on the right, and the Xucar and the Guadalaviar on the left. Here we find the nucleus, and, as we may say, the knot of the whole chain, Mount Cayo, which seems to be the reservoir of all the waters that rise in springs around this point, and take their course towards the two seas. This same chain, still advancing towards the south, forms a mass from whence the Guadiana flows, and further on the Guadalquivir; it then stretches on and terminates at Cape de Gatte. Let us now reflect, that the rivers which rise within this chain, in a manner divide it, into so many large valleys and intermediate plains, yet leaving, in the intervals, considerable ramifications, all of which are attached to the principal trunk. Just as they all flow in parallels towards the ocean, so do the mountains which overhang and swell them with their waters, run in parallel ridges from the mountains of the Asturias in the north to the Alpuxarras in the south. Thus, the mountains of St. Andero, which join the Pyrenees, run along between the Douro and the sea. The mountains of Guadarrama, which separate Old from New Castile, run between the Tagus and the Douro. Another chain which divides New Castile from the plains of La Mancha, rises from the north-east to the south-east, between the Tagus and the Guadiana; in this we find the Sierra de Guadaloup. On the other side of the Guadiana, is the famous Sierra Morena, from which we descend into the beautiful plains of Andalusia, which are watered by the Guadalquivir, and overlooked by the last chain of mountains in Spain, the Alpuxarras, which extends to the coast." The other remarkable mountains, besides those mentioned in the preceding extract, are, the Sierra Nivada, situated nearly in the centre of the kingdom of Granada, and which takes its name from the circumstance of its summits being constantly covered with snow. It is seen from an immense distance, and is well known to mariners, its highest peak, called Mulahacen, being 1824 fathoms above the level of the sea. The Sierra de Mondonedo covers the whole extremity of the north-east of Galicia, and extends to the north as far as Cape Ortugal, and to the Atlantic ocean on the west. The Sierra d'Occa, one of the principal ramifications of the Pyrenees, stretches across the southern parts of Spain, and the Sierra d'Orihuela, a lofty and extensive mountain, is situated on the boundaries of Murcia and Valencia.

Spain abounds with rivers and rivulets, many of which become impetuous torrents upon the melting of the snows, or after heavy falls of rain. They expand themselves over the country, and sufficiently serve for the purposes both of commerce and of agriculture. With the exception of the Ebro, all the principal rivers run into the Atlantic, and some of them are navigable to a considerable extent. The Ebro rises in the mountains of Asturias, near Reinosa, and after pursuing a south-eastern course of about 380 geographical miles, enters the Mediterranean below Tortosa. This river was once navigable as far as Logrono, about 60 leagues from its embouchure, but at present it is very difficult of access, being obstructed by shifting banks of sand, which increase and diminish in size, and which change their situation after storms and the swelling of the water. The Guadalquivir, the ancient *Boetis*, which gave its name to the district of *Boetica*, has its source in the Sierra Morena. It flows into the Gulf of Cadiz, a distance of 300 miles, and is navigable for large vessels as high as Seville. The Guadiana originates near Cuidad Real on the north side of the Sierra Morena. Where it springs from the ground, it forms several small lakes; and the apertures through which the water flows, are called the eyes of the Guadiana. It falls into the Gulf of Cadiz, and its circuit is nearly equal to that of the Ebro. The Minho rises in the Sierra Mondonedo and is said to derive its name from *minium*, or vermilion, which is found in abundance in its neighbourhood. It separates Galicia from Portugal, and falls into the Atlantic, after a course of 160 miles. The Douro springs near the ruins of the ancient Numantia, on the frontiers of Aragon and Navarre, and crossing Leon and Portugal, reaches the Atlantic below Oporto. Its course is 350 miles. The Tagus has its source near Albarrazin, in a spring called Abrega, and holding a course of 450 miles, embouches into an arm of the Atlantic in Portugal. The other rivers of less importance are the Guadalaviar, the Xucar, and the Sagura, which run into the Mediterranean, and the Ansa, which empties itself into the Bay of Biscay.

Many attempts have been made to improve the inland navigation of this country, but almost every project has had a similar result, and still remains unexecuted. The navigation of many of the rivers, which in the time of the Romans, were covered with barks and gallies, has been completely neglected, and has become impracticable. During the reign of Philip II. in 1580, the navigation of the Tagus was established from Lisbon to Alcantara. It was afterwards, according to a plan of Jean Baptiste Antonelli, carried as far as Toledo; and at the lower part of that city, the quay where the boats were loaded and discharged, still bears the name of *Plazuela de las Barcas.* This navigation, however, entirely ceased in the beginning of the 17th century, but the cause of its cessation is unknown. In the succeeding reigns, various plans were suggested for again opening the river, and also for cutting canals from Madrid to Aranjuez, and from Aranjuez to Alcala de Henarez, which, however, were never carried into effect. The establishment of canals between the inland and maritime provinces, have also been frequently attempted, but none of them have been fully executed. Of these, the most important is the canal of Aragon. It was begun in 1529, and after frequent and long interruptions, it is now brought nearly to a conclusion. But the success of this enterprise was greatly owing to the efforts and indefatigable zeal of a citizen of Saragossa; and to him Aragon is chiefly indebted for the revival of its industry and its commerce. This canal commences near Tudela, in the kingdom of Navarre, and from thence to where it discharges itself into the Ebro, its extent is about twenty-six leagues and a half. It has been proposed to carry forward this undertaking to the opposite coast, through Navarre and part of Biscay, which would thus form a communication between the Bay of Biscay and the Mediterranean. Several bridges are constructed upon it; and it has every where outlets to convey the water to the neighbouring lands, for the purposes of irrigation. This canal has cost upwards of £135,000 sterling. The canal of Campos, which was intended to open a communication between Old Castile and the Douro, passing by Valencia and Duenas, and extending to Segovia, is still in an unfinished state; and even the part of it which had been completed, has been so entirely neglected, that the excavations are insensibly filling up by the falling in of the earth. The canal of Manzanarez was undertaken for the purpose of supplying Madrid with provisions and other articles. It was to extend from the bridge of Toledo as far as the river Xarama, which was to be rendered navigable to form a communication with the sea. A part has been executed, and seven sluices constructed; but the scheme appears to be relinquished. Another canal was projected and determined upon some time ago, to open near the palace of the Escurial, extend to the Tagus, join the Guadiana, and abut on the Guadalquivir, below Anduxar. This canal would have passed through great part of Spain, and would have been attended with the most solid advantages; but the death of Le Maur, who furnished the plan, and was commissioned to see it constructed, suspended this important enterprize. Various similar undertakings have been in contemplation, both for the purposes of commercial communications, and the irrigation of the country, but they have been abandoned, or permitted to languish through the want of resources.

The climate of Spain is greatly influenced by local causes, such as elevation of site, proximity to the sea, or to a chain of mountains, &c., for while the mean temperature of the elevated plains is 59° of Farenheit, that of the coast from the 41° to the 36° of Lat. is between 63½° and 68 degrees. But, in general, it is very dry, and consequently exposed to severe droughts, which have frequently occasioned famines and epidemic diseases. Mariana mentions that, in 1210, "a great scarcity was felt in the kingdom of Toledo; there was not a drop of rain for nine successive months, insomuch that the husbandmen were forced to quit their lands and their dwellings, to seek an asylum in other provinces." It has, however, been deservedly praised as equal if not superior, to that of any country in Europe. According to Laborde, "the climate of New Castile is more mild than that of the old; in the former the winters are temperate, and the summers very hot: in the latter, the plains are very temperate, and the mountains as well as the parts bordering on them, very cold; there are even some parts of the low country where the cold is severely felt in winter. The skies of both are very fine, almost always clear, serene, and of a beautiful blue, but those of New Castile are the most constantly so; in some parts of the old, it is often cloudy.

The climate of Valencia is very temperate in winter, hot in summer, but refreshed by breezes from the sea; dry in the interior, somewhat moist in the plain of Valencia, generally inconstant, and subject to winds. The sky is usually clear and blue, except in the plain of Valencia, where the atmosphere is slightly thickened by the vapours rising from the great quantity of water collected there for the purpose of irrigation.

Catalonia, considered with regard to its numerous plains, is the most temperate province of Spain; the winters with some exceptions, are mild, and the heat of summer is not often extremely violent; but the hills and valleys bordering upon the Pyrenees are very hot in summer, and cold in winter, at which time the summits are covered with ice and snow. The higher parts are here less subject to variations of the atmosphere than the lower: these latter, especially on the side of Barcelona, experience continual changes: it varies rapidly, sometimes in the same day, from hot to cold, from dry to wet, from calm to stormy, and from a clear sky, to rain or cloud. The air is dry in the interior, and moist on the sea coast, especially in the basin in which Barcelona is situated. The east and south-east winds are those which blow with most frequency and violence in the parts near the sea. They bring with them a constant moisture and often rain.

Aragon is much drier and cooler than Catalonia; its temperature is even rather cold than hot: yet its plains and valleys are sometimes scorching, and a keen cold is felt upon its mountains. Winds are frequent and violent. The sky is clear, and more constantly so than in the maritime parts of Catalonia. The vicinity of the Pyrenees renders storms frequent in this province during the summer.

Navarre being situated among the Pyrenees, is a cold tract: its winters are usually very severe.

Biscay, comprehending the three districts of Biscay, Guipuzcoa, and Alava, is cold; the winters are sharp, and the summers temperate; it is dry in the interior, and moist on the coasts, where the cold is less felt. The sky is often cloudy and the air loaded with fogs.

The Asturias are mild near the sea, but cold farther up the country and upon the mountains: there are frequent and violent winds; the sky is seldom very clear, but rather cloudy; the air is moist and it rains frequently.

The climate of Galicia is very similar in all respects; its sky is the most cloudy of any in Spain, and more rain falls here than in any other part.

The climate of the kingdom of Leon varies in different tracts. In the eastern part it is very similar to that of Old Castile; in the north and west it resembles that of Galicia; and in the south it is similar to that of Estremadura.

Estremadura is a very hot and dry country, where the heats of summer are very violent, and the winters extremely mild. Its air is usually very dry, and its skies are perhaps the finest and brightest of Spain.

Andalusia is very hot on the coast, temperate in the interior, very cool at the foot of the mountains, and cold on their summits. It is a dry country, though watered by several rivers, and is exposed to several winds, especially near the sea. The east is the most prevalent near the Mediterranean; and a wind sometimes blows there from the south-south-east called the *Solano*, which has a very dangerous effect upon the human frame, and occasionally produces a state very similar to phrensy.

The climate of Murcia is cool upon the mountains, temperate towards the sea and at the foot of the mountains in the south, but very hot in the valley which is watered by the river Segura, and in which the city of Murcia stands, as well as in the Campo de Lorca, and burning in that of Carthagena. It is very dry, except in the valley of Segura, where it is almost always moist. The skies of this kingdom are most beautiful, almost always clear, bright, calm, and of a brilliant blue; on which account this country has been named the most *serene* kingdom of Murcia."

The natural history of Spain presents a vast field of inquiry, but it has hitherto been but little cultivated; so that our account of this department of science must be very general and imperfect. The highest ridge of mountains, between Daroca and Saragossa, are composed of argillaceous schistus and freestone, probably resting on granite. Those in the neighbourhood of Ansuela are limestone with shells, and sometimes contain beds of red gypsum with crystals of the same colour. The mountains north of Madrid, and also those surrounding Toledo are granite; and those to the north of Leon, which rise in bold and rugged rocks, are chiefly marble or limestone resting on a basis of argillaceous schistus. The higher regions of the Sierra Morena are granite; the lower, argillaceous schistus with gypsum and limestone; and the branches of the Sierra Nivada near Malaga present limestone and marble, surmounted by argillaceous schistus. On the south-east of the city of Granada are found rocks, which, on a basis of shingle, present sandstone with shells, surmounted with pudding stone; but in general the rocks are gypseous with strata of the same substance crystallized. The soil of La Mancha is sandy, and the rock gypsum; in fact gypsum appears to be as abundant in Spain as chalk is in England. The south-east part of the kingdom seems calcareous. The mountain of Montserrat in Catalonia is a compound of calcareous stone, sand, and pebbles, cemented together, and forming the kind of aggregation known by the name of pudding stone; and the cathedral of Murcia is built with a kind of limestone resembling the roe of a fish. The hills near Cape de Gatte are supposed to be volcanic.

The gold and silver mines of this country must in former times have been both numerous and productive, as the Carthaginians drew immense quantities of the precious metals from their colonies in Spain; and afterwards the Romans, when it became a province of the empire, explored its treasures with extraordinary success. Polybius informs us that the silver mines near Carthagena yielded 25,000 drachms daily. "Cato, after his proconsular government of this province, brought into the treasury of the republic no less than 25,000 lbs. of silver in bars, 12,000 lbs. of coined silver, and 400 lbs. of gold. Helvius from his province of Andalusia alone, brought into the treasury 37,000 lbs. of coined silver, and 4,000 lbs. of silver in bars. Minutius exhibited on his triumph 8,000 lbs. of silver in bars, and 300,000 lbs. of silver coin: and Flaccus returned from Spain with a treasure of 124 crowns of gold, 31 lbs. of gold in bars, and 70,000 lbs. of coined silver." Many vestiges of gold and silver mines are still in existence, but scarcely any of them are in operation; and what are so are very unproductive. Several, which were in a state of activity in the seventeenth and eighteenth centuries, are now abandoned, either in consequence of an influx of water, or for want of resources. Mines of lead and also of copper are very numerous and considerably abundant. The principal lead mine, which is wrought on the king's account, is near Linares, in Andalusia. The ore, which is galena, when analyzed, produces from 60 to 70 and 80 lbs. of lead per quintal, and three quarters of an ounce of silver. It is wrought at a small expense, and furnishes annually about 12,000 quintals of lead. Iron abounds in almost every province, but the most celebrated mine of this description is that of Samosostro in Biscay. The ore forms an irregular bed between three and ten feet in thickness, under a stratum of whitish calcareous rocks; and is of the species called by mineralogists *spathose iron*. It yields about 30 per cent., and the metal is soft and ductile, and perhaps the most malleable of any in Europe. A mine of antimony, belonging to the king, is wrought near Santa Cruz de Mudela, in La Mancha. The ore is very abundant and rich, the mineral being in almost a pure state; and sometimes lumps of metal will occur, weighing from two to three hundred pounds. A very abundant and productive mine of mercury and cinnabar united, also wrought for the king's benefit, is situated in La Mancha, near Almaden. The cinnabar is generally mixed with a large proportion of pyrites; but is often found in masses of great purity, one lb. of ore yielding ten ounces of mercury. Mines of rock-salt, and also salt springs and marshes, are found in many parts of Spain.

Three of the most productive of the former, with two of the latter, besides five salt pits in the environs of Cadiz, belong to the king. The two salt marshes furnish annually about 6000 tons, and the five pits about 1,600,000 quintals of salt. But the most remarkable mass of this mineral is the mountain of salt near Cardona in Catalonia. It is nearly three miles in circumference, and 500 feet high, without cleft or crevice. The salt of which it is composed is very white; and the river Cardonero, which washes its base, is so impregnated with salt that fish cannot exist in its waters within three leagues below the mountain. Some beautiful specimens of this substance, perfectly transparent, are manufactured at Cardona into various ornamental articles, such as crosses, figures of saints, chandeliers, &c. Amethysts, agate, chalcedony, and garnets are found near Vich, in Catalonia, and at Cape de Gatte, in Granada; and the marbles of Spain are abundant and valuable.

With respect to the botany of Spain, we refer the scientific reader to the Flora Hispanica of Joseph Quer, and the work of Cavenilles; and must confine ourselves to a few general notices on the subject. While the plains of this extensive country produce a great variety of curious and useful vegetables, the mountains are covered with rare and valuable plants well worthy the attention of the enterprising botanist, particularly Gaudaloupe, in Estremadura; Moncayo, in Aragon; Pineda, Guadarrama, and Cuença, in New Castile; Carascoy, in Murcia; Pena-Colosa, Mongi, Aytona, and Mariola, in Valencia; and the Pyrenees. The extensive and arid tracts of heath present a gayer and richer profusion of plants than those of any country in Europe. Among the thick woods of the yew-leaved fir, and stone pine, and the groves of cork trees, "the traveller is regaled with the fragrance of numberless aromatic plants, the mastick thyme, spike lavender, common and Spanish sage and rosemary. The golden blossoms of the gorse, a plant chiefly found in England and in Spain, and the crimson, flesh-coloured, and snowy flowers of the arborescent heaths mutually heighten each other; the elegant lithospermum fruticosum entangles itself among the thickets of dwarf myrtle, and every spot of sand or dry rock, forsaken by other vegetables, is adorned and perfumed by the cistus; of this plant there are no less than fourteen species natives of Spain, all of them eminently beautiful for their broad silken blossoms of pure white and yellow, with deep crimson eyes; the laurel-leaved cistus is most frequent in Old Castile, but the commonest of all is the gum cistus, a most elegant and fragrant shrub from six to seven feet high, which occupies whole miles of dry rock, and, on this account, forms a very peculiar feature in the scenery of Spain." The flat sandy tracts on the sea-shore are occupied by the sea daffodil, and some coarse kinds of grass; and in the neighbourhood of Alicant and Barcelona are extensive plantations of the *falsola fativa*, from which are manufactured annually some thousand tons of barilla, which is partly exported, and partly used for the preparation of fine Spanish soap. The calcareous rocks on the coast abound with samphire, tree violet, tragacanth vetch, caper bush, and esparto grass; this last, on account of its extraordinary toughness, is used for making ropes, mats, chair bottoms, and other similar purposes. In the woodlands the trees are neither so large, nor is the foliage so ample, as in England and Germany. There are several clumps of chestnut and box; but the great mass of the woods consists of the evergreen sweet oak, intermixed with the wild olive, the kermes oak, the walnut and carob tree. The almond, along with the sumach, fix themselves in the crevices of the rocks; and the laurel, the bay, the lauristinus and Portugal laurel attain to such a height as to afford a cool and shady summer retreat. In deep and rich soils a number of beautiful bulbous rooted plants appear in early autumn and spring, of which the most common in the Spanish landscape are, two species of asphodel, yellow amaryllis, jonquil, clustered hyacinth, dog's tooth violet, orange and martagon lily, and wild tulip. The banks of the rivers are adorned with the oleander, laburnum, tamarisk and myrtle; the fallows and dry thickets abound with the fan-palmetto, yellow lupin, Spanish and white broom; and in the hedges are found the laurel and common passion flower. The high mountains in the maritime districts are crowned with the finest timber; the oak, the lime, the birch, the mountain ash, the yew, the beech, the larch, the holly and the juniper, grow to a considerable size. In the interior provinces, however, trees are very rare; and whole districts are almost entirely destitute of wood.

Besides the domesticated animals, of which the most important in Spanish zoology are the horse, the mule, and the sheep, wolves are met with in all the higher and mountainous parts of the country; wild boars are found in some of the mountains of Valencia; lynxes and ibexes in the Sierra de Cuença, and in the valleys of Gistau and Aure; and roebucks in Navarre. Bears occur in several parts of the great Pyrenean chain, and especially on certain mountains in Aragon and Old Castile. In general, the birds, quadrupeds, reptiles, and insects of this country, are the same as those found in the southern provinces of France. The rivers abound with fish, of which those in highest estimation are from the river Tormes, some of them weighing above 20 lbs. The tench of some lakes in New Castile are remarkably fine and delicate, and are taken in great plenty during the months of May and June. The *Coccus ilicis*, or gall insect, familiarly known by the name of *Kermes*, which affords the fine crimson dye, so highly esteemed by the ancients, abounds in many parts of Spain. These insects feed upon the leaves of the *Quercus ilex*, or ever-green oak, and are collected in great quantities as an article of commerce, or of domestic manufacture.

Chap. II.—*Agriculture—Soil—Productions—Forests—Pastures—Domestic Animals.*

From the genial nature of the climate, and the general fertility of the soil, Spain, in the reign of Augustus, became the granary of the Roman Empire. It continued to be an exporting country until the expulsion of the Moors, when the Spaniards, deprived of the skill and industry of this people, and unaccustomed themselves to agricultural pursuits, allowed some of their most productive districts to lie waste; and, at present, this country is under the necessity of importing from foreign states a large supply of corn for the subsistence of its scanty population. Scarcely two-thirds of the land is now under cultivation. Commons are so frequent that, for six, eight, or ten leagues together, not the smallest trace of culture appears: and what land is under tillage, with the exception of a few districts, presents only a languid system of slovenly husbandry. Many attempts have been made at different times, and by various encouragements, to rouse the spirit and invigorate the system of agriculture; but a variety of obstacles are still in operation which tend to impede its advancement, and also the prosperity of the country. The principal of these obstacles are, 1. The deficiency of agrarian strength; and, 2. The *Mesta*, or the privileges granted to sheep proprietors in preference to agriculturists.

Spain does not nearly possess power adequate for the cultivation of her territory. Out of a population of above ten millions, scarcely two millions and a half are employed in husbandry; and this diminished number is owing to several causes:—1. The facility afforded in this country for persons to enter into the church, which induces many to become students who would otherwise be employed in agricultural pursuits. These receive their education at the monastic school, and often depend entirely upon public alms for their subsistence. 2. The crowd of mendicants and vagrants which infest every corner of this kingdom. 3. The great number of officers belonging to the different judicial courts and departments of government. 4. The swarms of domestics which are here retained as a principal object of luxury, and the greater part of whom are unprofitable, and even injurious to their master's service. And 5. The continual emigration from Galicia especially to Portugal, where from sixty to eighty thousand Spaniards are generally reckoned to reside. This want of agricultural strength is greatly aggravated by the loss of much time, arising from the multiplicity of feast days, the heat of the climate, and the indolence of the peasantry. The Spanish labourers consume a great part of the day in taking their *siesta*, and smoking their *cigarros;* and besides the usual feast days, which are now abridged to forty-one, and when they are obliged to attend mass, they seldom neglect to celebrate the different feast days of the titular saints of particular parishes, the patron saints of private families, and the guardian saints of individuals, which is just so much valuable labour lost to the community.*

The greatest obstacle to agricultural improvement, however, is the *Mesta*, which is a name given to an incorporated company of proprietors of migratory sheep, who are endowed with particular privileges highly prejudicial to the interests of agriculture. This association is formed chiefly of the nobles, persons in power, members of rich monasteries, and ecclesiastical chapters. Their flocks are united into one collective body, which does not strictly attach to any district, but travel backwards and forwards twice in the year, passing part of it in one place and part in another. The pastures upon which they feed are similar to the commons in England, and are denominated *waste lands*, which are prohibited by the legislature from ever being enclosed, or brought into a state of cultivation. These flocks they call *Merinos* or *transhumantes*, and consist usually of about 10,000 sheep in each. The number of the whole has varied at different periods, but at present they may be estimated at nearly 5,000,000. Each flock is conducted by an officer called a *mayoral*, who has under his authority fifty shepherds, with as many dogs. He has the sole management of the sheep, directing their route and choosing their pastures. They commence their migrations the latter end of April or beginning of May, and leaving the plans of Estremadura, Andalusia, Leon, and the two Castiles, where they winter, they repair to the mountains of the two latter provinces, and those of Biscay, Navarre, and Aragon. Toward the end of September, they descend from the mountains, and again repair to the warmer parts of the country, generally wintering on the same pastures, which they had grazed the preceding year, and where most of them had been yeaned. "The journey which the flocks make in their peregrinations is regulated by particular laws, and immemorial customs. The sheep pass unmolested over the pastures, belonging to the villages, and the commons which lie in their road, and have a right to feed upon them. They are not, however, allowed to pass over cultivated land, but the proprietors of such lands are obliged to leave for them a path ninety *varas*, or about eighty-four yards in breadth. The whole of their journey is usually an extent of one hundred and twenty, thirty or forty leagues, which they perform in thirty or thirty-five days." The Mesta has its peculiar laws, which are digested into a code entitled, *Leys y ordenanzas de la Mesta*, and there is also a particular tribunal consisting of four judges, under the title of *Honrada consejo de la Mesta*, whose jurisdiction extends to all matters that are in the slightest degree connected with the interests of the mesta, and who are particularly watchful against any infringement of its privileges. Of the numerous grievances to which this system has given rise, the following are stated by Laborde as the most vexatious, and the most opposed to agricultural improvement. 1. The number of persons it employs is very great, 40,000 or 50,000, which are so many subjects lost to the state, as to the purposes of agriculture and population, as they almost never marry. 2. An immense extent of highly valuable land is converted into pasturage, and produces comparatively nothing. 3. The cultivated lands which lie near the route of the flocks to and from the mountains, are subject to continual trespass, which is committed with impunity, for in vain do the owners appeal against such abuses, and solicit indemnity. The damages sustained on these occasions are so much greater, owing to the season of the year in which the journeyings of the flocks are made. The first is when the corn is generally far advanced in its growth, and the second when the vines are loaded with grapes. 4. The commonable pastures also, which are in the line of the route, are equally devastated, so that the flocks belonging to places in the vicinity can scarcely find a bare subsistence. 5. The flocks of the Mesta are unprofitable for agricultural purposes, for never being folded upon the arable land, they consequently contribute nothing towards their fertilization. The directors and shepherds are dreaded in every

* The Count de Capomanez calculates the sum lost every feast day by the suspension of labour, comprehending tradesmen, manufacturers, &c., as well as husbandmen, at sixteen millions of reals, equal to £166,666, 13s. 4d., and this for forty-one feast days amounts to £6,833,333, 6s. 8d. sterling.

place through which they pass, for they exercise a most insufferable despotism, the consequence of the improper privilege which they possess, of bringing whoever they may choose to insult before the tribunal of the Mesta, whose decisions are almost invariably in favour of its servants.

These grievances have frequently called forth the protestations of the public, and even the general states of the realm have repeatedly requested the suppression of the Mesta. But for a long series of years these calls were made in vain, till towards the middle of the 18th century, when the government found itself obliged to pay some attention to such powerful appeals. A committee of inquiry was then formed, and has continued for above half a century, but without proposing one remedy for any of its evils, so that the interest of a few powerful individuals still obtains the advantage over the public good. In a memoir, addressed to the Supreme Council of Castile, by the Patriotic Society of Madrid, on the advancement of agriculture, and drawn up by one of its ablest members, and a disinterested patriot, Don Gaspar Melchor de Jovellanos, we find the following observations on this subject: "The members of that body, (the Mesta,) have always aimed at soliciting peculiar privileges, and having been sufficiently powerful to obtain and extend them, have invariably given the most decided resistance to every system proposed for enclosure. Not pleased with possessing the privilege of keeping lands, once under pasturage, for ever in the same state; not content with preserving and extending the *canadas*, (roads for the sheep); not satisfied with the right of successively participating in all the public pastures, and obtaining an universal fictitious franchise, directly in opposition to the meaning and intent of the ancient laws; the Mesta wishes also to alienate individual property. Its laws perpetuate the prohibition of enclosures; its courts support this prohibition with increasing zeal; its oppressions eternize the laying open estates, and by its undue influence and authority the liberty of proprietors and their tenants is annihilated." "Even the very existence of such a pastoral assembly, on which such privileges have been conferred, is an outrage upon all law and reason, and the one by which it subsists the most prejudicial of all. Were it not for the existence of such a fraternity, which combines the opulence and power of the few against the imbecility and wretchedness of the many, and who form a body capable of resisting the representatives of the provinces, and even of the whole nation, who, for two centuries past, have found all their zeal vainly exerted in favour of agriculturists, and proprietors of stationary cattle; were it not for such a fraternity, how could privileges so unbounded and shameful be maintained." "Sufficient has been advanced, and the subject is so evident, that you should not refuse to pronounce a prompt sentence of dissolution upon this powerful association, annul its abused privileges, abrogate its unjust regulations, and suppress its oppressive tribunals. Then would disappear for ever that convention of nobles and monks, turned shepherds, who traffic under the revered sanction of political magistracy. This would eventually produce subsistence for stationary cattle, restore liberty to agriculture, to property its just rights, and allow reason and justice to exercise their proper offices."

There are various other impediments in this country to the progress of agriculture, of minor importance indeed when compared with the Mesta, but which all form additional discouragements to its improvement, namely, the difficulties attending the transporting of heavy articles, particularly in the central provinces, from the want of canals and good roads; the uncertainty of a market for farm produce, owing to the frequent changes in the laws respecting exportation; the high price of labour, and the various imposts, tolls, and taxes, which the local magistrates lay upon the productions of the soil, according to the price for which they are supposed to sell.

The soil of Spain is almost in every part excellent; and it requires only a little assistance to render it both valuable and productive. But the industry of the inhabitants is paralyzed by the oppressive restrictions and exactions of the government. Their implements of husbandry are in general rude and imperfect. The plough in many provinces is composed entirely of wood, and has neither coulter, fin, nor mould-board; but instead of these, some of them have two wooden pins placed near the tail of the share, and so disposed as to lay the furrow in high ridges; and others have only the tail of the share divided, so as to perform the same operation as the heel and ground wrist of our ploughs. Mr. Townsend has given a description and drawings of several of these ploughs. Those near Oviedo he represents as of the most clumsy construction. The coulter is fixed in a beam by itself, with two oxen and a man to work it; the plough then follows in the same tract, the point of the share only being shod with iron; and although the land is mostly strong and requires to be well ploughed, this instrument merely scratches the ground. There the harrows have no iron, and are used only for maize; the wheat and barley being always left unharrowed. In Catalonia they use a light plough drawn by two oxen, or one strong mule, and their harrows have iron furniture; but instead of a roller to break the clods they use a board, on which a boy stands, and drives the mule which draws it. In the rich vale of Huerta near Alicant, and also in the vale of Valencia, the earth is never allowed to rest. They use a one-horse plough, and never attempt any thing more than to pulverize the soil, which is easily done, as it is mowed eight or ten times a-year. "Wheat is put into the ground the beginning of November, and is reaped the middle of June, when they obtain from twenty to forty for one. Barley is sown in October, and in May they receive from eighteen to twenty-four for one. Oats are in the ground from the middle of October to the middle of June, and yield from twenty to thirty for one. Maize follows the barley as the second crop in the same year, and with a favourable season gives at the end of October a hundred for one. Rice, commonly sown about the first of April, is transplanted in June, and in October rewards the farmer forty fold. Beans may be put into the ground either early in the autumn, or in the beginning of the year. Hempseed is scattered on the land in April, and is cleared about the middle of July. The intermediate crops are vetches, cabbages, cauliflowers, carrots, turnips, cucumbers, melons, sandias, and a variety of other esculents. Thus with a warm sun, plenty of water, and a rich choice of crops, suited to every season of the year, the grateful earth repays the labours of the husbandman at least three times in the course of twelve or thirteen months." In some places particularly on the coast, they often sow barilla for a fallow crop, which is one of the most valuable productions of the country. After the land is well manured and ploughed they smooth its surface with boards instead of harrows, and sow the seed only in wet weather in January and February. When the plant is about the size of a shilling, they clear off all the weeds, and in September they collect the crops, which yield from ten to twelve quintals on a fanega of land, about an English acre. This crop, however, is liable to be instantaneously destroyed even at the moment of harvest, by a beetle, a species of *scarabeus*, depositing its larva in the roots of the plant. The foxes also are particularly fond of it, and will in one night lay waste an entire field.

A very particular mode of cultivation prevails in Biscay. The ground is dug up with an instrument called a *laya*, which resembles our dung grape with one of the outer prongs taken away, and the clods being broken with a mattock, are left to pulverize during winter by the action of the frost. In the spring the clods are again broken by means of harrows and wooden beetles, and afterwards levelled by a cylinder; deep holes about two feet apart, and in a straight line, are then made with hoes, in which are deposited seeds of Indian corn, French beans, peas, pompions, &c. and filled up with manure. When the plants appear above ground, the suckers both of blossoms and ears are cut away, and, when dried, constitute an excellent fodder for cattle. After the crop is cut, which happens about the end of September, the land is sown with corn without any farther preparation than covering the seed with the plough. In the course of the winter it is hoed to destroy the weeds, which operation is repeated in May and June; and the harvest commences about the end of August, when the stubbles are depastured. The light lands are allowed to rest for one year; but the stronger lands a few months after, undergo the process of the laya, and are again manured and cropped.

The manures generally employed are dung from the stables and sheepfolds, and the sweepings of houses and streets. In some districts of Guipuzcoa, the fields are covered with a marly earth which greatly fertilizes the land; and in Valencia the upper layer of the high roads, which is supposed to be impregnated with excrementitious particles, and the sand from the unpaved streets, which has been long subjected to the tread of animals, are carefully collected, and form an excellent manure for strong soils.

In a country like Spain, however, where the soil is generally dry, and the climate warm, nothing in the shape of manure is so beneficial to the land as regular irrigation. "In the northern provinces, situated at the foot of the Pyrenees, and the mountainous country branching from that Alpine chain which extends far into the interior of Spain, scarcely a district can be found where irrigation would not multiply threefold the produce of the soil; and there are large tracts of land which can yield nothing, or at best a scanty pasturage, unless assisted by the benefits of irrigation." This fertilizing system, however, is either neglected or not properly understood throughout the greater part of the kingdom. The lands which lie contiguous to rivers or streams are made to profit a little by their situation; but the art of conveying water above the level of the land by means of canals, and distributing it properly over the surface according to the quality of the soil, is very seldom practised. In Asturias, owing to the mountainous nature of the country, it would be difficult and expensive to profit in this way by its numerous streams; but the rivers of Leon, which supply a vast body of water, are suffered to run unheaded through extensive plains, without the inhabitants deriving the least advantage from them for agricultural purposes. The practice of irrigation is equally limited in Old and New Castile, though these provinces are watered by a multiplicity of rivers. It is almost entirely neglected in Aragon, and it scarcely deserves to be mentioned in Estremadura and La Mancha. But Catalonia, Valencia, Murcia, and some parts of Andalusia, form an exception to this general indifference to the means of agricultural improvement. In these provinces the system of irrigation is extensively and successfully prosecuted; and in Granada the skill and industry of the Moors are perpetuated by the numerous reservoirs and canals still in existence, which they formed for the purposes of watering and fertilizing their land.

Spain produces a great quantity of wheat, which is of a most excellent quality, plump, well grown, and well flavoured. It yields a very white flour, and a small quantity of bran, and the pellicle or skin is so thin, that, in the process of grinding and dressing, it does not lose more than a fifteenth, while the corn of the north of Europe loses a fifth. The difference which exists in the quality and quantity of bread produced from a given measure of each is also very considerable; and it is on this account that the wheat grown in Andalusia sells at Seville for nearly double the price of that imported from the north of Europe. The principal wheat districts are Andalusia, Old Castile, Aragon, and Murcia, which, besides supplying their own population, grow a sufficient surplus to satisfy the demands of the neighbouring provinces; while few of the other provinces produce what is necessary for the consumption of their inhabitants. Barley and maize are cultivated to a considerable extent throughout the kingdom; very few oats are grown; and rice is confined chiefly to Catalonia and Valencia. The crops in this country, however, are often exposed to severe droughts; and a hot and blasting wind occasionally prevails which instantaneously blights and scorches the tender blade. Severe scarcity is sometimes the consequence; but the disastrous effects of famine are in a great measure prevented by the judicious measures of the government, who many years ago formed an establishment, by which subsistence is provided for the inhabitants, in case of ungenial seasons or bad harvests. "Magazines or store-houses, denominated *positos*, are erected in various parts of the kingdom to the number of more than five thousand. When it is requisite to establish any of these granaries, every occupier of land is obliged to bring and deposit a certain quantity of corn proportionate to the extent of his farm. The following year he takes back the corn he had thus deposited and replenishes the empty garners with a larger quantity, and thus he continues annually to increase the stock, by these increments called *creses*, till a certain measure of grain is deposited; then every one receives back again the whole corn which he has furnished, and replaces it by an equal quantity of new corn. Whenever a scarcity happens, these repositories are opened and the corn dealt out to the people at a moderate price. In some places seed corn is also distributed to necessitous husbandmen, who are bound to restore as much in lieu of it the ensuing harvest."

Though flax is produced of an excellent quality, particularly in the central provinces, yet its cultivation is much neglected. More attention seems to be paid to the raising of hemp, which is successfully and profitably cultivated in Biscay and Galicia. A considerable quantity, about 168,000 quintals, is grown in Catalonia, Valencia, and Aragon; and it also forms a part of the produce in some parts of Andalusia and Old Castile. The hemp and flax raised in the interior districts of Spain are of a shorter and finer fibre than those of the northern provinces, and are consequently better adapted for general use, and capable of being better and more expeditiously bleached.

The sugar-cane at one time was extensively cultivated in Spain, but owing to the introduction of West India sugar, this species of produce is now almost entirely neglected, except in Granada, where a sufficient quantity is still raised to supply a considerable manufacture of sugar, and the canes produced in this country are usually disposed of to Provençal merchants, who buy them for the purposes of fermentation. Madder is grown in several of the provinces, but particularly in Old Castile and Andalusia, where are reckoned above two hundred mills for grinding the root, and which produce annually 7500 quintals of fine madder. The plants from which soda is made are almost all indigenous in this country. Some of them are cultivated with great care, especially *barilla*, (the *Salsola soda* of Linneus,) and *agua-azul*; but others grow wild in great abundance. The largest plantations of the former are found in Murcia and Valencia, which alone furnish 300,000 quintals of soda. The cultivation of saffron has long been on the decline, and is now confined chiefly to Murcia, which supplies annually about 150 quintals. Honey is produced in every district, but that which is most esteemed for the delicacy of its flavour is collected on the mountains to the north of Alicant in Valencia. The mountains of Cuença afford about 1000 quintals of honey, and forty-one and a half quintals of wax.

Though the soil of Spain is in general favourable to the growth of fruit trees, yet their cultivation in the interior and western provinces is entirely neglected; but in the other districts of the kingdom almost every species of fruit is produced. "Catalonia produces a considerable quantity; several districts in Aragon have scarcely any but fruit bearing trees; Biscay and Guipuzcoa abound with varieties; the four kingdoms of Andalusia are still more abundant; and the whole of the kingdom of Valencia is covered; the latter, in conjunction with Aragon, supplies Madrid and the greater part of New Castile. The fruit of Biscay, Guipuzcoa, and Catalonia is good; of Aragon and Andalusia, excellent; and that of the kingdom of Valencia the most beautiful, but less succulent and less delicate in the flavour."

Olive trees abound in almost every part of the country, but there is a considerable difference in the flavour and size of the fruit. The olives of Aragon are sweeter than those of Catalonia, and both are surpassed by those of New Castile. The olives of Valencia, and also those which grow in the vicinity of Seville are very large and beautiful: and as they contain a small quantity of oil, are more agreeable to the palate, and are generally preferred for eating. The olives of Seville were in high estimation among the Romans, and still retain their celebrity: but the best and most adapted for pickling are those grown in the districts of Alcala and Guadayra. The oil, however, of Spain is by no means equal to the fruit, and this arises from the way in which it is extracted. Oil of the finest quality might be obtained were only the necessary precautions taken in its manufacture. But the fruit is often over ripe, black and shrivelled, before it is gathered; the putrid and sound are indiscriminately mixed together, and it is allowed to remain for some time collected in heaps before the oil is expressed, all which tends to produce that sharp and often rancid flavour which is so observable in Spanish oils. In some districts, however, more attention is paid to the manufacture of this article; and when proper precautions are used, olive oil is produced not inferior in quality to the best oil of Provence. The principal oil districts are Granada, Seville, New Castile, Aragon, Catalonia, Murcia, and particularly Valencia. The annual produce of the three last provinces is about 266,600 quintals; and the district of Malaga contains 500 oil presses constantly at work during the season.

Almonds are very abundant in Catalonia, and in the environs of Malaga; but the most delicious are those which are grown at Ibi in Valencia. There they have a particular method of cultivating almond trees. They engraft them on the wild almond, which is supposed to bring them sooner to perfection. The fruit produced in this way is superior to any in Spain. The husk is smooth, and they keep fresh for several years, while the others often spoil in a short time. Fig trees are very numerous in Biscay, Aragon, and Catalonia; but the greatest quantities grow in Valencia and some districts of Andalusia. Those in the neighbourhood of Jaen and Ronda are most esteemed. Quantities of this fruit are dried both for exportation and home consumption: and Andalusia exports annually, by the port of Malaga alone, nearly 100,000 quintals. Nut trees are very general throughout Spain, but they are most successfully planted in Biscay and Catalonia; the latter province producing annually 105,000 bushels, of which 78,000 are exported.

This country abounds in vines, especially its eastern and southern provinces, but they are most numerous in Andalusia; and the kingdoms of Seville and Granada are usually denominated the *wine-vaults* of Spain. In many districts, however, very little attention is paid to the kind of soil on which the vines are cultivated; and, in general more regard is had to the quantity than to the quality of the fruit; for though this plant thrives best upon a gravelly slope, and produces grapes of a very superior flavour to those grown on a rich level soil, which is more congenial to the production of corn: yet vineyards are indiscriminately planted upon either, as if both situations were equally well adapted to its culture. The general method of planting is by cuttings, which are not permitted to grow very high, and consequently form very stout stocks; but upon sandy soils the stocks are sometimes set in small round hillocks about two feet and a half in height, and separated about three feet distant from each other. Poles for supporting the vines are not used in Spain: but espaliers are numerous in Andalusia and Valencia, on which are produced grapes of an extraordinary size, the branches frequently weighing twelve and fourteen pounds. In the districts around Malaga they gather the grapes at three different periods of their ripening. In the month of June those called *early* are gathered, which yield a wine of the consistence of honey; but the greater part of these are dried for raisins. The second crop is collected in September, which furnishes a clearer and stronger wine; but the real Malaga wine is formed from the last crop, called *tardies*, which is gathered about three weeks later. Besides the Malaga grapes, which are excellent, those of Aragon, Valencia, and Granada, are next in estimation. There is a small white grape, peculiar to Biscay, which has a very thin skin and is of an acido-saccharine flavour. The muscadine grapes of this province are also good and very similar to those of Frontignac.

The principal wine districts are Malaga, producing annually 700,000 quintals; Aragon 537,840 quintals; Catalonia 180,000 quintals; Valencia 955,000 quintals; and Murcia 320,000 quintals. The best red wines are those of Aragon, which possess a good body, and are very rich; those of La Mancha are pleasant, but thin and weak; those of New Castile are generally harsh and poor; those of old Castile are very light; those of Murcia are luscious and heavy; those on the plains of Valencia are below mediocrity, but those on the hills with a southern aspect are of a very superior quality; those of Granada have an agreeable scent and pleasant flavour; and those of Biscay are destitute of body, rough and sour. Many districts of Spain produce excellent sweet wines. The wine of Alicant in Valencia, and that of Carthagena in Murcia, are both good and very similar in their quality. Some muscadel wine is made in Aragon, and also in New Castile at Faencaral in the vicinity of Madrid. Navarre produces the wine of Tudela and of Peralta; the former much like Burgundy, though not so delicious, and the other a sweet wine not unlike the wine of St. Lawrence, but stronger and more grateful. But Andalusia is particularly famous for sweet wines. The wine of Montillo is very excellent, and those of Xeres, or *Sherry*, and Rota are well known. The most esteemed, however, is Malaga, of which there are two different sorts principally distinguished by connoisseurs, *Lagrima* and *Guindas*. The former is the unpressed wine from the grapes of the best districts; and the other is the common Malaga, in which are infused the soft buds of a cherry tree, the fruit of which, called in Spanish *guindas*, gives its name to this wine. Distilleries for making brandy are confined chiefly to Aragon, Valencia, and Catalonia; and this last province produces annually about 50,000 pipes.

Dried grapes or raisins are prepared in considerable quantities in Valencia, and in the environs of Malaga; and constitute an important branch of commerce. The latter district furnishes annually 300,000 quintals, of which 250,000 are exported: and the former 40,000 quintals, of which 33,000 are exported. The Malaga raisins are of a very superior quality, and obtain the highest price in the market, being both larger and of a more delicate flavour than those produced in other places. They are simply dried in the sun without any other preparation, and consequently retain all their juice: while those of Valencia are steeped in boiling water sharpened with a lye made of vine stems, and then exposed to the sun and air till they are sufficiently dry; by which process much of their substance is lost by escaping through the skin: part of it indeed crystallizes on the outside of the fruit, and forms a saccharine crust, which hardens in the colder countries to which they are exported.

Forests are numerous and extensive in the maritime provinces of Spain; but the interior is almost entirely destitute of wood. This scarcity of timber arises principally from the many absurd restrictive statutes existing in this kingdom respecting woods and forests; and from the prohibiting of enclosures throughout a great portion of the country. It cannot be expected that proprietors of land will incur the trouble and risk the expense of forming plantations, or pay any attention to their management and preservation, while they are prevented from raising enclosures to defend them from the depredations of the idle, and the encroachments of cattle; and the timber of which they cannot dispose of but at the will of the government. What inducement can proprietors have to cover their land with wood who must "submit to have their trees marked with a stamp of slavery, which places their disposal in the hands of another; to solicit as a favour, and pay for the permission of cutting a single tree for private use; to shroud and lop in a prescribed time, and subjected to certain regulations, and to sell the wood, whether agreeable to themselves or not, at a stated price; to allow the inquisitorial visits of official surveyors; and to make returns of the state and number of trees in their respective plantations?" Were these restrictions abolished, and timber become exclusively private property, the country would soon be rich in beautiful and extensive forests. The mountains of Catalonia are covered with beech, pines, evergreen oaks, and cork trees; and elms and willows fringe the margins of the rivers. In the plains, olives, almonds, walnuts, oranges, lemons, figs, plums, pears, apples, cherries, apricots, and peaches are everywhere abundant and flourish to an astonishing extent. Valencia abounds with trees of almost every description, but Carob trees, palm trees, olives, and mulberries are particularly prevalent; and not only are the mountains and hills, but the valleys and plains are clothed with forests. Some parts of Murcia, as the Huerta, produce an immense number of different kinds of trees, especially the mulberry; in other parts scarcely a tree appears for leagues together. Andalusia is equally defective. Fruit-bearing trees are exceedingly numerous in the plain of Granada, where are also woods of ash, elm, and white poplars more than four miles long: but the plain which leads from Cantillana to Seville, an extent of nearly thirteen miles, presents nothing except here and there a sprinkling of miserable olives. Many of the mountains, however, are well clothed with lentisks, cistuses, and evergreen oaks; and others with firs, yews, and cork trees. Estremadura, Leon, and the two Castiles, are but scantily adorned with sylvan scenery. Some of their mountains are covered with pines and oaks of different species; and in the plains of New Castile are some large forests of olives. Fruit trees abound in the Asturias, especially apples, which afford a considerable quantity of cider. Aragon and Navarre have a few oaks and pines, with some cork, ash, and cedars. Biscay, however, exhibits more extensive forests than any province of the kingdom. The mountainous part of Guipuzcoa is beautifully clothed with wood, and the hills are covered with evergreen oaks, hard oaks, chestnuts, and various kinds of fruit trees, particularly apples, and a great variety of shrubs. Orchards are abundant in the cultivated parts, where are immense quantities of figs, cherries, walnuts, peaches, and a variety of delicious pears. In some parts of Spain, more particularly in the two Castiles, Estremadura, and Andalusia, the acorns of the evergreen oak, which in other parts of the country serve only for food to the vilest animals, are eaten by the inhabitants and considered a delicacy. The ladies are particularly fond of this fruit, which they call *bellotas*, and which they use either raw, or roasted upon the coals like chestnuts. The taste is said to be very similar to that of walnuts, and when roasted more delicate.

Spain abounds with excellent pastures. The Spanish Pyrenees, and the collateral range of mountains, which ramify and extend into the provinces of Catalonia, Aragon and Navarre, are covered with them. The mountains of Asturias, Galicia and Andalusia, together with the plains of Estremadura, almost wholly consist of pasture land. New Castile abounds in grass, and the territory of Vellon for several leagues from Madrid is covered with beautiful and rich meadows, finely interspersed with a diversity of trees. The best grasses are found in Old Castile; and the mountains of Burgos are clothed with the richest herbage. Notwithstanding this abundance of pasture land, few horned cattle are reared in this country, except in the Asturias and some parts of Castile, and these are by no means adequate to the average consumption of the inhabitants. This deficiency is supplied by importation from other countries, especially from France. In the neighbourhood of Burgos, however, this branch of rural economy is very successfully cultivated. Cows constitute the principal wealth of the inhabitants; and their milk is manufactured into excellent cheese and butter. A sufficient quantity of the latter article might be made in this district to supply the demands of the whole kingdom; but the people are deficient in industry, and are unacquainted with the proper method of curing by salting and preserving it in casks. Mules form an important class of Spanish animals. They are employed as beasts of burden, and for agricultural purposes; and are generally preferred to horses and oxen for domestic use. The greatest attention is consequently paid to the breeding and rearing, and also to the proper breaking and training of these animals to fit them for the respective services in which they may be subsequently employed. The most esteemed are to be found in La Mancha, and also in Andalusia and Leon; but the numbers reared are not sufficient for the service of the country, and a large importation is annually made from France. The Spanish horse owes his high reputation to the care of the Moors; and the breed which this people introduced still exist in the province of Andalusia. The strongest horses are bred in Asturias; but the most beautiful in Andalusia; and this animal, though of a low stature, possesses almost perfect symmetry of form, carries his head remarkably well, and shows a bold fore-head; but is unable to sustain much fatigue. Those in highest estimation are reared in various parts of the kingdom of Cordova; and the royal stud at Cordova contains six hundred animals of all ages, among which are twenty stallions. There is another stud established at Aranjuez, where are reckoned twenty stallions, and four hundred mares. Great attention is paid to the preservation and increase of the native breed; and every precaution is used to prevent any admixture of a foreign race. The importation of foreign horses is absolutely prohibited; and there are also severe enactments against the exportation of Spanish horses. It was in contemplation, however, to try the experiment of crossing the breed, and for this purpose a hundred beautiful mares were brought into the royal studs from Normandy. This may be the means of introducing more bone and hardihood into the Spanish horse, and render him in every respect more adapted for military purposes. But notwithstanding the greatest care the breed has much degenerated; and the number of good horses is daily decreasing. The food of horses and mules in this country is generally straw, which in some provinces is chopped, and in others given whole. Hay is very rare; and oats are seldom given as provender, barley being substituted in their stead. Carob beans, mixed with bran, are very generally used both in Valencia and Catalonia.

Spain appears to have always abounded with flocks; and its breed of sheep has been long celebrated as perhaps superior to any in the world for the delicacy of the mutton, and the beauty of the fleece. The wools of Betica and Cantabria were in high esteem at Rome for their fineness, colour, and length of fibre. The excellence of the wool of this country is said to be owing to the crossing of the Spanish breed by the introduction of English sheep, which took place "in the year 1394. When the hereditary prince of Castile, son of king Henry the Third, married Catherine, the daughter of the duke of Lancaster, that princess brought with her from England a numerous flock of peculiarly fine sheep. Those animals so throve in the climate of Castile that they speedily formed one of the most considerable branches of commerce: the manufacture of cloth flourished in proportion, and so rapidly, that in the year 1419, the deputation of the kingdom requested the prohibition of the sale of foreign cloth, lest it might injure the use of the national fabrics." The sheep of this country are distinguished into two kinds—the *migratory* sheep, and *stationary* sheep. The former receive the appellation of Merinos, and have been already mentioned when treating of the Mesta; the latter always abide in the fields, and by night are penned in the sheep folds; and amount to nearly eight millions. The greatest number of them pasture in the provinces of Andalusia, Catalonia, and Valencia; and while the owners of the migratory flocks derive little more benefit from them than the profit of the wool; the lands where the others are fed are strengthened and enriched, and rendered capable of producing vigorous and flourishing crops of grain. In September the sheep are ochred, their backs and loins being rubbed with red ochre or ruddle dissolved in water; and this practice is supposed not only to defend the animal from the inclemency of the approaching winter, but also to improve the quality of the fleece. Sheep-shearing commences in May. It is introduced by a pompous preparation, and is considered a time of feasting and recreation. "One hundred and twenty-five men are usually employed for shearing a thousand ewes, and two hundred for a thousand wethers. Each sheep affords four kinds of wool, more or less fine, according to the parts of the animal whence it is taken. The ewes produce the finest fleeces, and the wethers the heaviest: three wether fleeces ordinarily weigh, on the average, twenty-five pounds; but it will take five ewe fleeces to amount to the same weight." The Spanish wools are, in general, excellent, being long and fine in the staple, and soft and silky to the touch. The annual produce is about 500,000 quintals, one half coarse, and the other fine wool. The Merino sheep afford the most valuable fleeces; and this superiority has been attributed to their being exposed to a more equal temperature, ranging upon the northern mountains during summer, and pasturing in winter on the plains and valleys of the south. In some districts, however, the stationary flocks bear an equally fine fleece, especially in the environs of Segovia, and in some parts of Estremadura and Aragon; but considerable differences exist between districts of the same province. In general, the finest wools are those of Segovia, Avila, Leon, and Aragon. Mr. Townsend states, that the wool of the Merino sheep is worth about twelve pence a pound, while that of the stationary flocks sells only for sixpence; and that every sheep is reckoned to yield a clear profit of tenpence to the proprietor, after all expenses are discharged.

Chap. III.—*Manufactures.*

In remote periods Spain was equally celebrated for the industry of its inhabitants as for the fertility of its soil, and the variety of its productions; and many of the useful arts had arrived at considerable perfection in the time of the Romans. Linen stuffs were first manufactured in the city of Zoela, in the district of Tarragona. and the cloths of San Fellippe, the ancient Sætabis, were famous throughout Italy and Greece. The manufacture of fine woollen cloths was also in a very flourishing state. The Spaniards had derived from the Phœnicians the art of dyeing these of a beautiful purple colour; and of this article great quantities were annually exported to Italy. They were equally celebrated for their mode of tempering steel; and the military arms of the Celtiberians were early adopted by their conquerors. The manufactures of Spain fell with the Roman power; and were almost annihilated while under the dominion of the Goths. But they were again revived by the genius and industry of the Moors, who formed several independent kingdoms in the centre of the country. The Spaniards, driven to the mountains, and having acquired a spirit of energy which they had not for a long time experienced, had the wisdom to profit by the example of the Arabs. Possessing the mines of Biscay, and the flocks of Leon, they retained the fabrication of woollen cloths and of arms; and allowed the manufacture of leather, linen, silk, &c. to remain almost entirely in the hands of the Moors. During the period between the middle of the 15th and the end of the 16th century, Spain is represented by her own writers as perfectly independent of foreign nations; manufacturing the greater part of its silk and wool; supplying the wants of its inhabitants from within itself; and exporting more manufactured than raw articles. This, however, is a very exaggerated picture, and is not supported by cotemporary historians, who make no mention of her manufactures, while they give an account of the quantity of wool and other raw materials exported from her shores. We know, however, that after the death of Philip II. a sudden and rapid change took place; and manufactures experienced an almost instantaneous decline, which nearly amounted to an absolute annihilation of trade. This revolution was produced by the combination of various causes; the expulsion of the Moors in 1614; a general taste for foreign stuffs in preference to those fabricated in the country; and the impolicy of the government in not only permitting the importation of foreign manufactures, but in laying a stamp duty, called *bolla*, upon articles manufactured in Catalonia, and a heavy tax upon silks. The effect of these measures was such, that the national manufactures were generally neglected, and in a short time almost absolutely abandoned. The manufactures of cotton, linen, gloves and swords, entirely vanished, and by the close of the 17th century, scarcely a vestige of its former prosperity remained. Such was the state of destitution in which Philip V. found the trade of Spain, when he ascended the throne in 1700. The intestine wars which accompany a disputed succession; and the low state of the national finances prevented for a time any attention being paid to the subject of manufactures. But Philip, having restored tranquillity to his dominions, and established the public revenue, induced his subjects to wear the national fabrics; and thus laid a foundation for the revival of trade, which was ably and cordially supported by his successor Ferdinand VI. This prince not only encouraged the formation of manufactories by peculiar privileges, and pecuniary assistance, but also established several at his own expense; and by giving employment to foreign artisans, induced many of them to settle in the kingdom. Charles III. followed his example, and greatly increased and multiplied the means of encouragement. A spirit of competition introduced life and vigour into trade; and though this regeneration was not equally prompt in all parts of the monarchy, yet gradually new branches of manufacture started up; and the different ramifications are now sufficiently numerous.

The woollen stuffs fabricated in Spain are, in general, of a very inferior quality, and cannot stand a competition with the woollen goods of foreign countries. This is owing, in a great measure, to their imperfect knowledge in the arts of fulling and dyeing, the latter being so badly executed that the colours are never permanent. From this general reflection, however, we may except the superfine cloths manufactured at Terrassa in Catalonia, and at Brihuega, Segovia, and Guadalaxara in New Castile. These are intrinsically of the most excellent quality, and not inferior to the best French cloths, though they do not possess their lustre. In Guadalaxara is an extensive manufactory of Vigogna cloths, which are so much esteemed and so difficult to procure. This establishment is maintained at the expense of the king, and is consequently making but little progress. Those employed in its management feel no interest in its success. Profusion, waste, and idleness, prevail in every department: and this undertaking, which would have prospered under private owners, is, under its present directors, scarcely able to support itself. Manufactories of coarse cloths, baize, flannels, swandowns, druggets, and other common woollen stuffs are scattered over the kingdom; but none of any extent, except at Puebla de Valencia, in Leon, which manufactures annually 5,000 pieces of flannel, estimated at L.18,840 Sterling. Woollen stockings are made at Burgos in Old Castile, and at Aulot, and Vich in Catalonia. Aulot supports 400 looms; the number woven at Burgos is considerable; and Vich produces annually 24,000 pairs. Numerous looms for blankets are established at Barcelona, but they are not collected in factories. Burgos has twelve factories for this purpose; but the finest blankets are made at Valencia, which furnishes annually about 63,000. This town also manufactures tammies to the amount of L.10,500 Sterling. Woollen carpets are woven at Cuença in New Castile; and fifty looms are employed at Aulot in making bands for woollen caps. An elegant manufacture of tapestry is carried on at Madrid, which was established by Philip V. in 1720. Its productions are carpets and tapestry, the subjects of which are often drawn from fable or history; and it affords daily employment to 80 persons, including dyers, drawers, designers, and all its various branches.

The silks of this country are in general stout and excellent; but destitute of the brilliancy observable in French silks. The damasks of Valencia are extremely beautiful; and that city produces mohair stuffs which appear superior to those of France and England. The manufacture of silk handkerchiefs and bands, employs 500 looms at Reus, 600 at Manresa, where are annually made 60,000 dozen of handkerchiefs. Barcelona produces a much larger quantity. This city possesses also an extensive silk-stocking manufactory, besides a considerable manufacture of ribands, and of gauzes. The stockings are of a loose texture, badly dressed and glossed: and very inferior to the French stockings. Few of them are worn in the country, being exported chiefly to America. The ribands are also thin and flimsy, possessing neither permanency nor brilliancy of colour. Silk taffeties, serges, common and figured satins, damasks, plain and flowered velvets, are made in various parts of Spain; but it is only at Toledo and Talavera de la Reyna that the looms for these purposes are collected in factories. The making of blond lace is confined chiefly to Catalonia, and is fabricated in the villages upon the sea-coast by poor women and children. The principal manufactory for this article is at Almagro in La Mancha, which gives employment to about twelve or thirteen hundred persons.

The manufacture of linen cloth is still in a very imperfect state in Spain: and there are only two considerable manufactories for this article in the kingdom. The rest is made in the towns and villages by what are called *custom* weavers, who work for private families. The greatest quantity, and the best, is made in Galicia. This province produces annually above 5,000,000 yards, of which nearly 790,000 are exported to America; 1,740,000 are sent to the two Castiles; and the remainder consumed at home. Excellent table linen is made at Barcelona, which also furnishes a considerable quantity of thread stockings. These, however, are of an inferior quality. In the district of Bayonne are manufactured annually about 100,000 pairs. Cordage, cables, and sailcloth, are prepared principally in the three marine departments, Cadiz, Carthagena, and Ferrol. Various other articles composed of linen thread, as nets for the hair, laces and tapes, are fabricated in different places; and at Barcelona this manufacture employs 12,000 persons.

The cotton manufacture has of late years greatly increased in Spain; but it prevails chiefly in Catalonia; and the principal factory for cotton cloths of different qualities is established at Barcelona. This city produces annually about 4,090,000 yards, valued at £369,000 Sterling. At Aulot 600 looms are employed in the manufacture of cotton stockings and caps; and Tarragona produces annually 9,000 pieces of cotton riband. Cotton spinning was first introduced at Barcelona in 1790; and there are now not less than 100 spinning factories, some of which are very considerable. Aulot has 200 spinning machines, and Reus 250. There are also two factories of this description at San Lucar de Barrameda.

Manufactories for preparing hides, skins and all kinds of leather are very general throughout the kingdom. The greatest quantity of sole leather is manufactured in the provinces of Aragon and Catalonia. At Aragon are tanned annually 800 quintals and 750 at Brea. A much greater quantity, however, and also of superior quality is prepared in Catalonia, which after the supply of its own consumption, furnishes annually 700,000 pair of soles; and further, exports leather to the amount of £41,660 sterling. Shoemaking is prosecuted to a great extent at Barcelona, which, besides supplying the demand of the contiguous provinces, exports large quantities to America.

The paper manufactured in this country is far from excellent, being deficient both in whiteness and texture. The number of paper-mills, which are confined chiefly to the kingdom of Aragon, amounted in 1776 to eighty-six, which were augmented in 1785 to one hundred and five; and are now above two hundred, fabricating annually 444,000 reams of paper.

The best delf-ware is made at Alcora and Manisez in Valencia; and the finest china at Madrid. At Valencia is a manufacture of delf paving tiles, which are finely varnished and beautifully painted, and with which they pave their apartments, and encrust the walls of their houses. These tiles are of different dimensions; and it takes a certain number to form a picture. The price varies according to the size of the tile, the beauty of the varnish, and the variety of the drawings, from fifteen shillings to £15, 12s. 6d. a thousand. There is a considerable demand for them, and they are said to be superior, both in beauty and strength to those used in Holland.

The principal iron forges are in Catalonia, Aragon, Asturias, and Biscay. Those in Biscay proper, and in the district of St. Andero, produce annually 124,000 quintals. In Asturias are forty-eight iron mills, of which nine are appropriated for bar-iron, thirty-seven for the nail trade, and two for copper. The cutlery of this country is in little estimation, being badly finished, worse polished, and destitute both of taste and elegance. The best is made at Solsona in Catalonia; but the greatest quantity at Albacete in Murcia. A manufactory of steel and brass needles and brass nails has recently been introduced into Valencia, and also into Catalonia; and the two most considerable pin manufactories are established at Corunna in Galicia. Polished arms, such as swords, hangers, bayonets, &c. of superior temper, are made at Toledo and Barcelona; and the best fire-arms are manufactured at Ripoli. Brass cannon are cast at Barcelona and Seville; and iron ordnance at Lierganez and Cavada.

The glass of Spain is in general of a very inferior quality; being both dark and destitute of lustre. The most beautiful and transparent is made at Pajarejo and Recuenco in Castile; and at St. Ildefonso, bottles are wrought of a superior quality, and white glasses, which are carved with great ingenuity. In this town also is established a manufactory for mirrors, which produces the largest that have yet been fabricated. They are sometimes from 100, 130, to 150 inches in height, and 50, 60, or 65 inches in breadth. The process of polishing is performed by a machine; and they are then transported to Madrid for the purpose of being metallized.

The only manufactory for tobacco is established at Seville; and is conducted on the government account. The snuff prepared here is made from the tobacco grown in the Brazils, the island of Cuba, and some other Spanish colonies. The leaves when dried are reduced into an impalpable powder; and then mixed with a very fine unctuous reddish earth found in the environs of Almazarron, a village in Murcia. The earth fixes the volatile particles of the tobacco, gives it various shades of red colour, and communicates to it an unctuosity and delicacy of scent. This preparation is called by the Spaniards *polvillo*, but by other nations *Spanish snuff*. Rolled and cut tobacco are also manufactured in this establishment; and it likewise monopolizes the sale of another kind of tobacco, used for smoking, and called *cigarros*. These are not prepared at Seville, but are imported from the American colonies; and the most esteemed are brought from the Havanna. There is a prodigious consumption of this article in Spain; and vast quantities are annually exported to foreign countries. This manufactory comprises 202 mills, which employ 1404 persons; and the annual proceeds of net profit, which accrues to the king, is estimated at about £833,333 sterling.

Saltpetre and gunpowder are made almost every where on the king's account; and the most considerable manufactory for the latter article is established at Villafeliche, which keeps seventy mills in constant employment.

The other manufactures of Spain are very unimportant, and we shall therefore content ourselves with merely enumerating the most considerable. Soap is made in a variety of places; and also hats; but the best are made at Badajos. Aquafortis and salt of lead are manufactured at Manreza in Catalonia; pewter buttons at Gihon in the Asturias; playing cards at Macharaviaya in Granada; white wax at Puerto de Santa Maria; potash at Valencia; veneered articles at Madrid; and gold and silver laced and brocaded stuffs at Talavera de la Reyna, which city consumes annually in this manufacture 4000 marks of silver and 70 of gold.

The manufactures of this kingdom in general, possess none of those qualities which give such a pre-eminence to similar articles at present manufactured in England and France; and the quantity produced, so far from allowing any exportation to other countries, is not adequate to supply her own wants and those of her colonies. Spain is therefore obliged to import large quantities of manufactured goods from Holland, England, France, and Germany; and the Count de Campomanez, in the year 1775, observed that eight millions of people belonging to the Spanish monarchy were clothed with foreign manufactures.

Chap. IV.—*Commerce.*

The commerce of Spain had the same periods of rise, decline, and revival, as its manufactures; and the same causes operated almost equally upon both. In the fifteenth and sixteenth centuries, the trade of this country extended to all parts of Europe. The cities of Almeria, Valencia, and Barcelona, pushed their commercial concerns into Syria, Egypt, Barbary, and the Archipelago; and Barcelona, under the kings of Aragon, had established factories in the extreme parts of Europe and Asia, as far as the Tanais, and was enabled to equip and maintain armed ships for the defence of her trade. At that period Spain had a large navy, and possessed a thousand merchant vessels, all constructed in her own ports. Few of these, however, belonged to native Spaniards; for while the principal manufactures were engrossed by the Moors, the Jews constituted their most intelligent and active merchants. The expulsion of this people in 1492, consequently gave a severe blow to the commerce of the country, from which it with difficulty recovered, during the following century, by the activity and wealth of the Moors. But when they in their turn were driven from the kingdom, its destruction became complete; and commerce and manufactures equally disappeared. By these impolitic measures, Spain was deprived of a great proportion of her wealth and population. Her shipping interest was annihilated; and what few ships she possessed were purchased from foreign yards. The monarchy in a short time became so enfeebled as to be totally unable to defend the small remains of her trade, and to repress the piracies of the Corsairs of Barbary, who not only seized all her vessels in the Mediterranean, but made incursions upon her coast, and carried off many of her subjects as captives. Many fruitless attempts were made at different times to revive the commerce of the kingdom; but these feeble and insufficient efforts served only to show the imbecility of the government; and it was not until the accession of the House of Bourbon to the throne, that a revival of trade could be said to be in operation. Philip V. was no sooner in quiet possession of the sceptre, than he devoted his attention to this subject; he encouraged manufactures, bestowed honorary rewards on trade, granted premiums to merchants, and instituted commercial boards. His subjects seconded his endeavours, and suddenly "displayed a spirit and activity of which they seemed incapable; the ports were filled, and the sea was covered with shipping; they ceased to purchase foreign built ships, but constructed them at home; their dockyards for shipbuilding quickly increased; and at present there are yards for building armed vessels at Ferrol, Cadiz, and Carthagena; and for merchant vessels at Bilboa, Corunna, Cadiz, and along the whole coasts of the kingdoms of Valencia and Catalonia. Notwithstanding, nearly the whole coasting trade of Spain is yet carried on by the French, the English, and the Dutch. The Catalonian, Valencian, and Biscayan vessels are the only national vessels which participate in this trade. The merchant vessels belonging to Spain are destined for the American rather than the coasting trade."

The internal and home trade of Spain is very inconsiderable for want of sufficient means of communication; and chiefly consists in the exchange of national produce and manufactures between one province and another. But this subject has been already sufficiently treated in our description of the different provinces. To these we must refer our readers, and also for an account of the various branches of foreign trade which are respectively peculiar to each. We shall merely give a short general statement of the principal commercial transactions which this country prosecutes with the other states of Europe, and with its American colonies.

The European commerce of this country is confined chiefly to England, France, Holland, Italy, and the Baltic, and may be considered as entirely passive. For though it exports immense quantities of its agricultural productions, it sends abroad none of its manufactured articles, except a few fancy goods from Valencia; but on the contrary imports them from all countries.

The wine trade suffered considerably from an impolitic regulation of Philip V. who during the war of the succession, prohibited the exportation of Spanish produce into those countries which were inimical to his interests. The English were of course driven to Portugal for a supply, and have ever since given a preference to the red wines of that country. The wine of Xeres or Sherry, however, and some sweet wines, are still received by England in considerable quantities. Catalonia exports to Italy 4000 charges;* and Valencia sends to England, America, and France 1,200,000 cantaras. The quantity of Xeres wine exported to different places amounts to 80,000 quintals; that of Malaga to 400,000 quintals; and that of Alicant is estimated at 800,000 reals.

The brandy trade is confined principally to the ports of Catalonia and Valencia. From the former are exported 20,000 pipes to Holland, Russia, Sweden, and Denmark, 10,000 to England, and 4000 to Guernsey and Jersey; and from Valencia, France and England receive annually 500,000 cantaras.

Spanish oil constitutes a principal article of exportation. That produced in the kingdom of Aragon is sent to France and England; that of Catalonia, to the amount of 8000 charges, goes partly to Holland and partly to France; and the quantity sent from Andalusia, by the port of Malaga, to England, Holland, and the north of Europe, is estimated at 20,000,000 reals.

Soda, barilla, salicor, and agua-azul, are exported in considerable quantities, by the ports of Alicant and Carthagena. The province of Valencia furnishes upon an annual average 100,000 quintals of barilla, 25,000 quintals of soda, and 4000 quintals of agua-azul; and Murcia exports 150,000 quintals, four-fifths of which go to France, and the remainder to England.

The exportation of fine wools is greatly encouraged by the Spanish government, on account of the very considerable duties which they bring to the revenue. The quantity annually exported amounted to about 125,000 quintals of washed wool, and 105,000 of wool in the grease, both of which are sent to Holland, France, and England. The same wools are returned in a manufactured state, in the shape of cloths, serges, swandowns, flannels, &c. and the remunerating price demanded by the foreign manufacturer absorbs nearly the whole of the money previously received for the raw material. Spain thus loses all the advantage arising from the employment of her own population; for were these wools kept in the kingdom they might serve both to extend the manufactures of the country and contribute to national wealth. Burgos is the staple for all the wools shipped in the ports of the Bay of Biscay; the remainder is exported by Barcelona, Grao, Cullera, Alicant, Carthagena, and Malaga, in the Mediterranean; a portion also passes by way of Seville and Cadiz.

The corn trade forms a considerable branch of Spanish commerce, but the least advantageous to the country. Though this kingdom be naturally fertile it frequently experiences a scarcity of grain, and is under the necessity of importing this indispensable commodity from France, Italy, Africa, Greece, and sometimes from the north of Europe.

The trade of tobacco is wholly in the hands of the government, and affords a very ample profit. Besides these principal branches of commerce, Spain exports a variety of other articles, viz. salt, fruits of various kind, sumac, anchovies, rice, palmes, kermes, nuts, cork both in boards and manufactured, madder, bar-iron, and anchors, lead, silk, and fancy articles called *azulejos*. The exportation of piastres, though prohibited by the government, forms a great object of speculation, and they are smuggled into France from the frontier provinces to a considerable amount.

The following table contains a general statement of the principal articles exported from Spain into the other countries of Europe.

* For the weights and measures of Spain, and their comparative value with those of England, see the conclusion of this article

Articles.	Quantities.	Value. Reals de Vellon.	Value. Sterling Money. £ s. d.
Wine from Catalonia	4,000 charges	256,000	2,666 15 0
Do. from Valencia -	1,200,000 cantaras	912,000	95,000 0 0
Do. from Alicant -		800,000	8,333 6 8
Do. from Xeres - -	50,000 quintals	12,000,000	125,000 0 0
Do. from Malaga - -	400,000 ditto	36,000,000	375,000 0 0
Brandy from Valencia	500,000 cantaras	12,000,000	125,000 0 0
Do. from Catalonia -	35,000 pipes	25,200,000	262,500 0 0
Dried Raisins from Malaga - - - - -	252,000 quintals	10,000,000	104,166 13 4
Do. from Valencia -	38,000 ditto	1,140,000	11,875 0 0
Dried Figs from Malaga	100,000 ditto	3,300,000	34,375 0 0
Do. from Valencia -	16,000 ditto	512,000	5,333 6 8
Walnuts from Catalonia	26,000 sacks	2,496,000	26,000 0 0
Chestnuts from Biscay		320,800	3,333 6 8
Nuts from the Asturias		800,000	8,333 6 8
Dates from Valencia -		400,000	4,160 13 4
Almonds from ditto -	3,000 quintals	630,000	6,562 10 0
Oil from Malaga - -		20,000,000	208,333 6 8
Do. from Catalonia -	8,000 charges	2,560,000	26,666 16 4
Barilla, Soda, Agua-azul } from Valencia	129,000 quintals	6,096,000	63,500 0 0
Barilla, Soda, Agua-azul } from Murcia	200,000 ditto	10,000,000	104,166 13 4
Kermes from Valencia	140 ditto	700,000	7,295 13 4
Cork from Catalonia -	30,000 ditto	21,600,000	225,000 0 0
Corks from ditto - -	1,200 ditto	862,996	8,989 10 10
Madder from Old Castile	4,000 ditto	6,400,000	66,666 13 4
Brooms from Barcelona		660,000	6,875 0 0
Wool washed - - -	125,000 ditto	64,000,000	666,666 13 4
Wool in the grease -	105,000 ditto	20,700,000	215,625 0 0
Salt from Valencia -	6,000 tons	888,000	9,250 0 0
Do. from Puerto Real		80,000,000	833,333 6 8
Total		341,233,796	3,640,018 12 2

The imports of this country are very considerable; but we have no means of ascertaining their amount. Spain receives

From Holland, linen drapery, common lace, tapes, cutlery goods, paper, and spices.

From Silesia, linen drapery.

From Germany, by Hamburgh, quantities of haberdashery.

From England, calicoes, iron and steel goods, fine cloth, quantities of cod fish and ling, whale oil and butter.

From France, calicoes, linen drapery, silk stockings, silks, camlets and other kinds of worsted stuffs, fine cloths, gilded articles, jewellery, iron and steel goods, haberdashery, perfumery, and spices.

The principal trade of Spain is with her American colonies. Previous to 1720, this trade, for two centuries, had been confined to the city of Seville by an absurd regulation of Charles I. in 1529, who, though he permitted merchants to freight vessels from Carthagena, Malaga, and the chief ports of Galicia, Asturias, and Biscay, bound them, under the penalty of death and confiscation of their cargoes, to return to Seville. In consequence of this exclusive system, and the heavy duties imposed upon all goods exported to, or imported from America, little business was done to advantage; and the contraband trade became very lucrative and extensive in its operations. About the middle of the 17th century, when the trade between Seville and the colonies was at its height, it never employed more than 27,500 tons of shipping. In 1720 the emporium was changed to Cadiz; and the whole American trade was carried on by twenty-seven galleons and twenty-three flotas, the smaller vessels being about 550, and the others between 800 and 1000 tons. The galleons sailed annually to Porto-Bello, for the commerce of Peru, and the flotas once in three years to Vera Cruz, for that of Mexico. During the annual fair at Porto-Bello, which lasted forty days, the merchants brought their gold and silver, with bezoar stones, Peruvian bark, and Vicuna wool; and received in exchange provisions and European goods. On the return of the fleets the market was glutted with colonial produce; and, as no single ships were permitted to sail in the interval, the occasional demand was left to be supplied by the contraband trade; so that the trade to Peru, when confined to the galleons, gradually decreased, insomuch that instead of employing 15,000 tons, it was reduced in 1748 to 2000. It began to revive, however, upon the introduction of *register ships*, which, upon paying a douceur to government, were allowed to make voyages between the sailing of the periodical fleets; and when Charles III. extended the privilege of a general trade between Vent, Buba, Hispaniola, Porto-Rico, Marguerita, Trinidad, Louisiana, Yucatan and Campechy; and the ports of Seville, Carthagena, Alicant, Barcelona, Corunna, St. Andero, and Gijon; this trade, "which," says Mr. Townsend, "had been like the summer's brook, soon resembled a great river, and enriched all the countries through which it flowed." This freedom of trade was no sooner established than the mercantile spirit availed itself of so favourable an opportunity; and in the same year 162 vessels sailed for America from the different ports of Spain.

But notwithstanding this permission to particular ports, the Spanish government has granted from time to time, exclusive privileges to chartered companies, which have in general greatly tended both to the injury of the mother country, and also to the oppression of those transatlantic provinces which have been subjected to the monopoly. The first of these was the Caraccas company of Guipuscoa, established in 1728. This company possessed the exclusive trade of Caraccas, with the privilege of reshipping by smaller vessels all its surplus commodities for Cumana and Guayana, with Trinidad and Marguarita, two islands at the mouth of the Oronoco, that they might exchange European goods for gold, silver, hides, tobacco, cocoa, sugar, and such other fruits as these countries produced. This trade was carried on by the ports of Cadiz and St. Sebastian, and employed twelve carrying vessels, with as many more for the suppression of smuggling, and 2,500 seamen. Cocoa became at last their staple commodity, and under their management its importation increased so considerably that the price of chocolate in the Spanish market fell one half. From the year 1770 to 1774, they imported 179,156 panejas of cocoa, 75,496 hides, 9052 quintals of tobacco, and 221,432 pezos in specie, arising from the sale of cocoa which had been sent to Mexico. This company, however, sustained many severe losses at the commencement of the American war, among which was the capture of a rich convoy by Lord Rodney, valued at more than £200,000 Sterling; and a few years afterwards it was completely dissolved, and its capital absorbed in a new establishment called the Company of the Philippines.

This new company commenced its operations in 1785, with a capital of 115,200,000 reals, and with valuable privileges granted to it for a term of twenty-five years. Previous to this establishment the trade of the Philippine islands was carried on by means of two large galleons which sailed annually; the one, from Acapulco, crossing the Pacific ocean, carried the treasures of America to the Philippines; the other returning by the same course, a distance of nearly 8400 miles, came to Acapulco laden with china ware, spices, tea, perfumes, silks, calicoes, muslins and printed linen, the produce of the East, which were bartered with the merchants from Lima for cocoa, quicksilver, and hard dollars. The direction of this traffic was immediately changed. The precious metals of Mexico and Peru were sent directly westward to the place of their final destination; and the productions of the East, to the same amount in value, was brought round by the Cape of Good Hope to Spain, where they were admitted under easy duties, with a drawback of one-third on their exportation. The prospects of this company were at first very flattering, but soon after it met with many unfavourable circumstances, and sustained very heavy losses; yet at the close of the year 1796 it had derived a profit of 22,000,000 reals. This traffic, however, had a tendency to injure the national manufactures, by the quantity of foreign articles, such as silks and muslins, which were imported; and as they had extended their speculations to Vera Cruz, Buenos Ayres, and to most sea-ports of South America, where no limited capital could stand in competition with their operations, had they met with the support they had reason to expect, they must soon have swallowed up the whole trade of Spain, and, in the issue, have been the ruin of that country.

"The chief trade between Spain and America consists in exporting a considerable quantity of Spanish manufactures, and importing a large quantity of gold and silver, the produce of the colonies. Spain sends to America a vast quantity of the fancy articles called *azulejos*, and coarse woollen, for clothing the troops, from Valencia; numerous iron utensils, quantities of marbled paper, dyed and printed cottons, and calicoes, from Catalonia; cotton stockings, 600,000 pieces of cotton ribands, and 80,000 dozens of silk handkerchiefs from the same province; from Galicia 50,000 pairs of knit thread stockings, 850,000 varas of linen drapery, table linen, tapes, hides, skins, and various kinds of dressed leather; numbers of silk stockings are sent from Talavera de la Reyna and Barcelona; quantities of silks and silk stuffs mixed with gold and silver, from Talavera de la Reyna, Toledo, Requena, Valencia and Barcelona; large quantities of writing paper from the kingdom of Valencia; about 200,000 reams of the same kind of paper from Catalonia, from whence are also sent 200,000 pairs of shoes; playing cards from Granada; and house brooms and brushes from Barcelona.

In return the colonies supply Spain with coffee, sugar, some cotton, tobacco, cocoa, leather, and particularly gold and silver, both in ingots and coined into money. Part of the precious metals belong to the king, and the remainder is imported on account of the merchants, being sent as the balance for articles obtained from Spain. Upon a moderate calculation the annual value of gold and silver imported amounts from five to six millions Sterling. In the year 1791 there arrived in the port of Cadiz alone, gold and silver, in money, bars, or ingots, to the value of 25,788,175 piastres, (£5,370,619.) This only includes the quantity known to be imported, from its having paid the duty; it is supposed what is clandestinely imported amounts to nearly an equal sum."

The following tables will give a brief view of the extent and value of the American trade. In 1778, when the American trade was first thrown open, the exports from Spain were,

	Reals de Vellon.	Sterling Money.		
In national merchandise	28,636,619	£298,298	2	3¼
Foreign merchandise	48,378,342	503,941	1	3
Total	77,014,961	802,239	3	6¼

Within ten years, in 1788 the exports were nearly quadrupled, as appears from the next table.

In national merchandise	158,223,239	£1,648,158	14	9¼
Foreign merchandise	142,494,290	1,484,315	10	5
	300,717,529	3,132,474	5	2¼
Imports from America in 1788	804,693,733	8,382,226	7	8
Excess of imports	503,976,204	5,249,752	2	5¼

This commerce is still chiefly carried on by the port of Cadiz, from which were exported in 1792 merchandise to the amount of 270,000,000 reals, and its imports amounted to 700,000,000 reals. From that period the Spanish trade with America has continued to increase; and America has equally profited by the freedom of traffic. The trade with Vera Cruz in the year 1802, amounted in imports to 21,998,588 piastres; and in exports to 38,447,367 piastres, of which sum three millions and a half were paid for cochineal, three millions for indigo, and one million and a half for sugar.

The information contained in the following tables, which we have selected from M. Cæsar Moreau's excellent Commercial Tables, will give the reader some idea of the trade between Spain and Great Britain.

Table of the value of British goods Imported into Spain.

	1824.		Annual average of ten years.
Woollen goods	£82,709	-	£119,473
Cotton manufacture	86,259	-	97,049
——— yarn	65	-	927
Linen manufactures	103,438	-	95,442
Silk do.	49,485	-	55,842
Hardware and cutlery	40,293	-	34,759
Iron and steel	20,095	-	22,223
Glass and earthen ware	9,293	-	13,896
Brass and copper	12,104	-	9,657
Haberdashery and millinery	6,534	-	9,565

At one period few national ships were employed in the trade of Spain. The number, however, has considerably increased. Catalonia alone possesses above a thousand vessels; and in the city of Cadiz are more than a hundred shipowners.

The following account of Spanish probity, in commercial transactions, is given by Laborde:—"Good faith and punctuality are generally prevalent among merchants, the instances of deception, negligence, fraudulent dealing, and non-fulfilment of engagements, so general in the trading world, being unknown, or not practised among them. Their integrity has been manifested on many important occasions: a few examples will be sufficient to justify this assertion. The fleets that sail from Spain to Porto-Bello, on their arrival attract a concourse of merchants, who give the silver coinage of America in exchange for the commodities of the European continent; and not a case of the former, nor a bale of the latter is opened, but all is received with a noble and mutual confidence upon the simple verbal assurances of the parties respecting the contents; and only one single instance of deception was ever known, for the space of two centuries, to have been practised. All the coined silver sent home in the year 1654 was found debased by the admixture of a fifth part of baser metal; but no sooner had the fraud been discovered, than the Spanish merchants appeared eager to support the whole loss themselves, and to indemnify all foreigners, with whom they had transacted business on that occasion. The treasurer of finance, *Du Perron*, was convicted as the author of the debasement, and for the crime was publicly burnt alive. The contraband trade of America furnishes daily new proofs of the probity which is evinced by the Spanish merchants; the French, English, and Dutch bear testimony to this high character, who lend their names, and in other ways assist the merchants of Spain; and scarcely an instance has occurred where these have not proved faithful to their engagements. Neither apprehension of danger, nor the attraction of gain can ever induce them to betray or deceive those who honour them with their confidence."

Chap. V.—*Population—National Character—Usages and Customs—Religious Festivals.*

When we consider that this country is one of the richest in the world, and possesses resources equal to any nation in Europe, we cannot but wonder at the deficiency of its population; for while England yields 169 inhabitants, France 174, and Naples 201 to the square mile, Spain has only 74. It is however agreed on all hands that, in more distant periods, this country was much better peopled than at present. Abundant vestiges indeed still exist of its former populousness. "The heights," says Laborde, "are covered with the ruins of Gothic castles, mansions, &c. and through the whole country appear dilapidated chapels, and other religious edifices in solitary places, situated in the midst of fields or uncultivated lands. The number of these in Catalonia, of which nothing remains but the names, is equal to a fourth part of those which at present exist. In Aragon are reckoned 149; in Catalonia 304; twelve in the kingdom of Jaen; 70 in the jurisdiction of Leon and Toro; 87 in Valencia; 11 in La Mancha; 194 in New Castile; and in Old Castile 308; constituting a sum total of 1141. Under the caliphs, kings of Cordova, 1200 villages enlivened the banks of the Guadalquivir, of which 200 scarcely are at present left. In the district of Malaga, to the west of that city, were 50 villages; and 16 only remain. A part of the diocese of Salamanca, in Leon, comprised 748 villages; which number is now reduced to 333. On the confines of the same bishopric 127 villages existed in the space of five leagues, and only 13 remain. Many of the villages and hamlets still subsisting present little more than ruins, and are in most instances reduced to a few houses, and a small number of inhabitants; 385 of this description may be enumerated in Aragon alone." Some idea may be formed of the loss in inhabitants which Spain has sustained, from the difference of population in some of its cities in ancient and modern times, as contained in the following table:

Cities.	Date.	Ancient population.	Modern population.
Tarragona	Under the Romans	2,500,000	10,000
Merida	Had a Roman garrison of	90,000	5,000
Truxillo	17th century	12,000	4,000
Montijo	Ditto	10,000	3,600
Seville	13th century	300,000	96,000
Cordova	Under the Caliphs	1,000,000	35,000
Medina del Campo.	16th century	60,000	6,000
Salamanca	Ditto	50,000	13,000
Burgos	Ditto	40,000	8,000
Valladolid	Ditto	60,000	20,000
Segovia	Ditto	38,000	12,000
Toledo	14th century	200,000	25,000
Cividad real	Ditto	25,000	9,000
Granada	15th century	250,000	50,000

Many causes for this depopulation have been assigned by different writers, of which we may enumerate the following as the most considerable. 1st, The plague, which spread over Europe in the years 1341 and 1348, made a most rapid and destructive progress in Spain, continued its ravages for three years, and carried off nearly two-thirds of the inhabitants. The same scourge renewed its desolations in the succeeding centuries, in 1483 and 1488, 1501 and 1506, and particularly in 1649, when, in the southern provinces, it swept away a population of more than 200,000; Cadiz and Seville alone lost 100,000 of their inhabitants. 2d, The expulsion of the Jews and Moors deprived this country of the most industrious and intelligent portion of her population. The former in 1492, to the number of 800,000, left the kingdom, and carried with them all the wealth and property which they had acquired by industry and trade: and in 1614, 2,000,000 of Moors were driven from their homes, and their towns and villages left desolate. 3d, The almost incessant and sanguinary conflicts between the Spaniards and Moors, which continued with little interruption for nearly seven centuries, and which terminated only with the taking of Granada in 1492 by Ferdinand, carried off many millions of Spaniards; and the civil wars, which have so frequently divided this kingdom, have probably been equally destructive of its population. 4th, The *Mesta*, by which immense tracts of land are converted into a state of pasturage, affords few means for the lower classes to obtain a subsistence by being employed in the labours of agriculture; and the 50,000 persons, who are engaged in taking care of the flocks, lead a wandering life, and seldom or never marry. Besides these, we may mention the constant emigration to America; the great number of unmarried monks and clergy; and the unremitted operation of a bad government. It would appear that the population of this kingdom had gradually decreased from the time of the Romans to the beginning of the 18th century; since which period, however, its increase has been uniform and rapid. Under the Romans, Spain is supposed to have contained at least twenty millions of inhabitants; in 1715 this number was reduced to six millions; but in 1799 it had increased to twelve millions.

The following table exhibits a state of the comparative population of Spain in 1788, divided into classes, when the population amounted only to 10,043,975.

Provinces.	Parishes.	Villages.	Secular clergy.	Convents.	Monks.	Nuns and friars.	Nobles.	Servants.	Individuals.
Andalusia	1,001	767	5,600	745	12,111	4,737	9,914	31,629	1,837,024
Murcia	101	108	1,077	91	2,000	646	4,704	6,408	337,686
Valencia	562	550	3,221	225	5,311	1,688	1,076	18,963	783,084

Royal demesnes	5	5	78	4	264	12	9	520	10,048
Total	20,378	19,219	60,240	3,094	49,270	22,337	478,736	276,091	10,043,975

Respecting the proportion between the extent of territory and the number of inhabitants, no very accurate estimate has ever been made in Spain. It is, however, stated in Hassel's "Satistique Europeenne," which is sufficiently correct for general purposes, that the whole of Spain contains 9053 German square miles, and 10,730,000 inhabitants, which will allow 1185 inhabitants for every German square mile, or 74 for every geographical square mile.

The people who now inhabit Spain have derived their origin from a variety of stocks, its soil having been occupied in succession by the Carthaginians, Romans, Goths, Arabs, and French. The original natives were in course of time confounded with their conquerors; and, as all of these nations introduced, in some degree, their own laws, manners, and customs, hence has resulted that diversity of appearance and character which is so observable among its present inhabitants. As the physical constitution of a people is almost uniformly influenced by the nature of the climate under which they live, and as every province of Spain differs materially in this respect, this circumstance may likewise in a great measure account for this variety. "The Castilians," says Laborde, "appear delicate, but they are strong. The Galicians are large, nervous, robust, and able to endure fatigue. The inhabitants of Estremadura are strong, stout, and well made, but more swarthy than any other Spaniards. The Andalusians are light, slender, and perfectly well proportioned. The Murcians are gloomy, indolent and heavy; their complexion is pale, and almost lead-coloured. The Valencians are delicate, slight, and effeminate, but intelligent and active in labour. The Catalans are nervous, strong, active, intelligent, indefatigable, and above the middling stature. The Aragonese are tall and well made, as robust as, but less active than the Catalans. The Biscayans are strong, vigorous, agile, and gay; their complexion is fine, their expression quick, animated, cheerful, and open." In general terms, the Spaniards may be described as rather below than above the middle stature, well proportioned, and of a swarthy complexion, with an intelligent countenance, regular features, and eyes quick and animated. The females are naturally beautiful, and the greater part are brunettes, of a slender and delicate shape, with a fine oval face, and black or rich brown hair. "They have large and open eyes, usually black or dark hazel, delicate and regular features, a peculiar suppleness, and a charming natural grace in their motions, with a pleasing and expressive gesture. Their countenances are open, and full of truth and intelligence; their look is gentle, animated, expressive; their smile agreeable; they are naturally pale, but this paleness seems to vanish under the brilliancy and expressive lustre of their eyes. They are full of graces, which appear in their discourse, in their looks, their gestures, and all their motions, and every thing that they do."

The dispositions and character of this people are perhaps even more diversified than their outward appearance; and there are not two provinces in which they are exactly alike. "The Old Castilians," says the author already quoted, "are silent, gloomy, and indolent; they are the most severely grave of all the Spaniards, but they possess a steady prudence, an admirable constancy under adversity, an elevation of soul, and an unalterable probity and uprightness; they are faithful, friendly, confiding, unaffectedly kind: in short, completely worthy people. Some districts have peculiar shades of character. The *Pariegos* are active and clever in trade, and are the pedlars of a great part of Spain. The inhabitants of the valley of Mena are robust, courageous, and employed in agriculture, they believe themselves descended from the ancient Cantabri. The *Maragatos* are lean, dry, frank, but the most taciturn of the Old Castilians; there are some among them who were never seen to laugh; they particularly addict themselves to the business of carriers.

The character of the natives of New Castile is nearly the same, but more open and less grave and taciturn; it is also somewhat modified in the districts bordering on other provinces. The qualities usually acquired by residing in or near a capital may be observed in them. The inhabitants of Alcarria ought to be distinguished from the rest, as simple, amiable, and industrious.

The inhabitants of La Mancha greatly resemble those of New Castile, but are more serious, more gloomy, and more laborious; they are a good kind of people.

Indocility and conceit make part of the character of the people of Navarre: they are distinguished by lightness and adroitness.

The Biscayans are proud, conceited, impetuous, and irritable, they have something abrupt in discourse and in action, and an air of haughtiness and independence: they are less sober than most other Spaniards; but are industrious, diligent, faithful, hospitable, and sociable. They have an open countenance, and a quick, animated, and laughing expression. The women are equally haughty and courageous. They labour in fields and at other works, where strength is required, like the men. The idea of something noble attached to being a native of Biscay, influences the character of the inhabitants of this province in a singular manner; it keeps up among them a feeling of dignity which gives a haughtiness to their carriage, and an elevation to their sentiments, even in the lowest stations of life.

The Galicians are gloomy, and live very little in society; but they are bold, laborious, very sober, and distinguished for their fidelity.

The Asturians participate in the character both of the Galicians and Biscayans, but they are less industrious than the former, less civilized, less sociable, less amiable, and more haughty than the latter. Their haughtiness, derived from the same source, an opinion of innate nobility, is also more marked, more repulsive, and less softened by their temper and manners.

The people of Estremadura are proud, haughty, vain, serious, indolent, and still more sober than the Galicians. They seldom go out of their own province, are afraid of strangers, and shun their company; but they are true, honourable and courageous.

The Murcians are lazy, listless, plotting and suspicious; they scarcely ever go out of their own country, and neither addict themselves to science, to the arts, to commerce, navigation, nor a military life; they only cultivate their land from necessity, and make but little advantage of a rich and fertile soil, a facility of irrigation, and a most happy climate. The common people are sometimes dangerous; they too frequently make use of the knife and the dagger; people of a superior condition lead a melancholy and monotonous life.

The Valencians are light, inconstant, and without decision of character; gay, fond of pleasure, little attached to one another, and still less so to strangers; but they are affable, gentle, and agreeable in the intercourses of society, and able, by their diligence, to ally the love of pleasure with industrious occupation. They are accused of being vindictive, and hiding under a calm and mild exterior their wishes and schemes of vengeance, till an opportunity offers of executing them in a safe and secret manner; but the hired assassins, formerly common in Valencia, have disappeared, and the people are daily becoming more civilized by the operation of wealth and prosperity.

The Catalans are proud, haughty, violent in their passions; rude in discourse and in action, turbulent, untractable, and passionately fond of independence; they are not particularly liberal, but active, industrious and indefatigable: they are sailors, husbandmen, and builders, and run to all corners of the world to seek their fortunes. They are brave, intrepid, sometimes rash, obstinate in adhering to their schemes, and often successful in vanquishing, by their steady perseverance, obstacles which would appear insurmountable to others.

The Aragonese are haughty, intrepid, ambitious, tenacious of their opinions, and completely prejudiced in favour of their country, their customs, and themselves; but prudent, judicious, able to appreciate foreign merit, good politicians, good soldiers, and zealous for their laws and privileges.

The Andalusians are boastful and arrogant; their discourse is always full of hyperbole; their expressions, their gestures, their manners, their tone of voice, their carriage, all bear the stamp of this prevailing disposition; in short, they are the Gascons of Spain. Of this country are the Majos, or bullying coxcombs, whose favourite weapon is the dagger, and they handle it with skill. Andalusia is a dangerous country in summer when the *solano* blows; a south south-west wind which blows from Africa, and the effects of which much resemble those of the *sirocco* in Italy, but are more obvious and violent. It inflames the blood, causes vertigo, and produces excesses of every kind."

There are, however, some traits of character which may be called national, and which are almost universal. Almost all Spaniards possess a natural dignity of sentiment, and have the highest opinion of their nation and themselves, which they energetically express by their gestures, words, and actions. They are very reserved, especially to strangers. Their address is serious, cold, and sometimes even repulsive; but under this apparent gravity they possess an inward gaiety, which sometimes bursts out, and, though usually noisy, is genuine, frank, and natural. The sum of their virtues is thus summed up: "They are sober, discreet, adroit, frank, patient in adversity, slow in decision, but wise in deliberation, ardent in enterprise, and constant in pursuit. They are attached to their religion; faithful to their king; hospitable, charitable; noble in their dealings; generous, liberal, magnificent; good friends, and full of honour. They are grave in carriage, serious in discourse, but gentle and agreeable in conversation, and enemies to falsehood and evil speaking. They are of quick and lively parts; intelligent, ingenious, fit for the sciences, literature and the arts." The Spaniards, indeed, possess many of these virtues in an eminent degree; but the defects of their character are equally conspicuous; and superstition and a bad government have degraded them far below the average of the other nations of Europe. One of the most prevailing defects in this people is their invincible indolence, and hatred of labour, which has, at all times, paralysed the government of their best princes, and impeded the success of their most brilliant enterprises. In every undertaking, even the most trifling, the Spaniard deliberates when he ought to act, and seems to be continually influenced by the spirit of one of the common proverbs of his country, "That one should never do to day what may be put off till to-morrow." The happiest eras of this nation have not been exempted from this fatal apathy, which has almost always kept them dependent on the industry of their neighbours, or at least far behind them in improvement; and the effects of which have been deplored by all their historians. "Sloth and idleness," said Sancho de Moncada in 1619, "are the prevailing vices of the Spaniards, and foreigners are so well aware of it, that they come running from all sides to bring us the products of their industry; they have reduced this poor kingdom of Spain to the condition in which the children of Israel were, when they were obliged to go and seek even the smallest instruments of labour among the Philistines." "In this country alone," says another Spanish writer, "are the mechanic arts held in dishonour; whence that multitude of idle people, and women of bad fame, and all the vices which accompany the want of employment. The result is, that our lands lie fallow, and that our country is a slave to the industry of strangers." This listlessness of disposition, however, is not so general but that there are some exceptions; and the inhabitants of some of the districts on the sea coast are conspicuous for their activity and industry. But this defect of the Spanish character is a virtue when compared with that depravity of morals which pervades every class of society in this country. The high and chivalrous spirit of a former age, when love, honour, and religion, maintained a generous rivalry, and gave birth to many splendid achievements, has been succeeded by a love of low intrigue and stratagems. The example of a dissolute court has given prevalence to practices which were before restrained, and has made that honourable which formerly had been attended with disgrace. Spanish jealousy, which was once proverbial, has given place to the most culpable indifference: and the most degrading connections have assumed among this people an authentic and respected character. The marriage ceremony is the prelude to the most ruinous gallantry. While it would be considered indecorous in an unmarried female to be seen alone out of doors, or sitting *tete-a-tete* with a gentleman, the married lady goes where she pleases, receives what company she likes; and even when indisposed in bed, she does not scruple to see every one of her male visiters. Many gentlemen are introduced to ladies of the first fashion, and visit them on the most familiar footing, without the least acquaintance, or even personal knowledge of their husbands. Immediately after marriage the lady must have, a matter of course, a *cortejo* or lover, who has in general a very strong hold upon her affections, and compared with whom the husband is a person of very secondary consideration. He attends her upon all occasions, in private and in public, in health and in sickness. When she sits at home, he is at her side;

when she walks out, his arm supports her; and when she joins in the dance, he must be her partner. This connection, however, is invariably attended with jealousy and suspicion. Both are conscious that there is no other band between them but the precarious tie of mutual affection; and each, therefore, must tremble at the approach of any one who might interrupt their union. Hence they are constantly engaged in watching each other's looks; and for want of confidence, renounce, in a great measure, the charms of social intercourse. "It sometimes happens," says Mr. Townsend, "that a lady becomes weary of her first choice, her fancy has fixed upon some new object, and she wishes to change; but the former, whose vanity is flattered by the connection, is not willing to dissolve it. In lower life, this moment gives occasion to many of those assassinations which abound in Spain; but in the higher classes, among whom the dagger is proscribed, the first possessor, if a man of spirit, maintains possession, and the lady dares not discard him, lest an equal combat should prove fatal to the man of her affections. In this contest the husband is out of sight, and tells for nothing." "It is reckoned disgraceful to be fickle; yet innumerable instances are seen of ladies who often change their lovers. In this there is a natural progress; for it cannot be imagined, that women of superior understandings, early in life distinguished for delicacy of sentiment, for prudence, and for the elevation of their minds, should hastily arrive at the extreme, where passion triumphs, and where all regard to decency is lost; as for others they soon finish the career. It is however humiliating to see some who appear to have been designed by nature to command the reverence of mankind, at last degraded, and sunk so low in the opinion of the world, as to be never mentioned but with contempt. These have changed so often, and have been so unfaithful to every engagement, that, universally despised, they end with having no cortejo. So general is this system, that there is scarcely a lady of respectability who has not her cortejo. The author already quoted mentions the circumstance of a gentleman in Carthagena saying one morning to a friend, 'Before I go to rest this night, the whole city will be thrown into confusion.' This he himself occasioned by going home an hour before his usual time, to the no small vexation of his wife and of her cortejo, whose precipitate retreat, and unexpected arrival in his own house, occasioned the like confusion there; and thus by successive and similar operations, was literally fulfilled the prediction of the morning." Though it would appear from this extract that married men do not hesitate to hold the situation of a cortejo, yet in this disgraceful connection the clergy in general hold the principal places; in the great cities the canons of the cathedrals, and in country villages the monks. The corruption of morals in general may be traced to the celibacy of the clergy; but the almost universal infidelity to the marriage vows in this country originated in the introduction of Italian manners on the arrival of Charles III. from Naples, connected with the previous want of reasonable freedom in the commerce of the sexes.

The Spaniards may in general be divided into two classes, nobles or Hidalgos, and plebeians. The former includes all those whose families, either by immemorial prescription, or by the king's patent, are entitled to particular privileges. This honour branches out through every male whose father enjoys that privilege, and thus Spain is overrun with *gentry*, many of whom earn their living in the meanest employments. The grandees hold the first rank, and are divided into three classes, which, however, differ from each other only in the form of the ceremonial to be observed by them when introduced at court. A grandee of the highest rank, when presented to the king, covers himself before he replies to the salutation of his majesty; one of the second remains uncovered till he has paid his compliments, but one of the third rank is not allowed to cover himself till he has paid his compliments, made his bow, and mingled with the crowd of courtiers. The character of these grandees is thus drawn by an admirable painter of Spanish manners; "surrounded by their own dependants, and avoided by the gentry, who are seldom disposed for an intercourse in which a sense of inferiority prevails, few of the grandees are exempt from the natural consequences of such a life; gross ignorance, intolerable conceit, and sometimes, though seldom, a strong dose of vulgarity. I would, however, be just, and by no means tax individuals with every vice of the class. But I believe I speak the prevalent sense of the country upon this point. The grandees have degraded themselves by their slavish behaviour at court, and incurred great odium by their intolerable airs abroad. They have ruined their estates by mismanagement and extravagance, and impoverished the country by the neglect of their immense possessions. Should there be a revolution in Spain, wounded pride and party spirit would deny them the proper share of power in the constitution to which their land, their ancient rights, and their remaining influence entitle them. Thus excluded from their chief and peculiar duty of keeping the balance of power between the throne and the people, the Spanish grandees will remain a heavy burthen on the nation, while, either fearing for their overgrown privileges, or impatient under reforms which must fall chiefly on them and the clergy, they will always be inclined to join the crown in restoring the abuses of arbitrary government." The privileges of this body are very important. They are alone admissible into the four military orders; they are exempt from certain imposts, from service in the militia, and from the billeting of troops. They are not liable to imprisonment for debt, except for arrears of taxes payable to the king; they cannot be confined in the common prisons, nor can their house, their horse, their mule, or their arms, be taken in execution. The nobility of Spain in 1788 amounted to 478,736, above $\frac{1}{12}$ of the whole population; of these 129 were grandees, and 535 marquisses, counts, and viscounts; but nearly one half of this privileged order belongs to the provinces of Asturias and Biscay.

The Spanish dress is now very much altered from what it was a century ago; and French fashions are daily gaining ground, especially among the higher ranks, and destroying entirely the national costume. During the seventeenth century, it consisted of light breeches, bound with garters, and fastened up with points: a short doublet, with large flaps, and hanging sleeves, covered with a frieze cloak, all of black; a round hat, usually turned up in front, and often adorned with a plume of feathers; a *golilla*, or white ruff, worn round the neck; a dagger at the girdle, and a very long sword. The accession of Philip V. however, introduced a total change; and the costume of France soon prevailed over that of Spain. Black was exchanged for the most varied and conspicuous colours; the old swords disappeared; and bags and queues came in place of the simple crop. The cloak and slouched hat are still much in use, except in the large cities, where they are seldom worn except in winter as a protection from the cold. Uniforms are very common, and a well-bred Spaniard would be ashamed to show himself without one. They are not confined to the military, but are worn by all the officers employed in the king's household, or attached to the treasury, post-office, &c. Judges, magistrates, and professors of the universities, are also distinguished by peculiar dresses. The nobility have an uniform for the holy week, which they wear at court and in town. The coat is of black velvet lined with crimson satin, with gold, or gold embroidered buttons, and facings of gold brocade on a crimson ground, or of satin of the same colour embroidered with gold. The waistcoat is the same as the facings, and the breeches are black. This dress is worn by the king and the royal family.

Women of rank in Spain have all adopted the French dress, which they wear at home, in their carriages, at visits and public spectacles; and assume the Spanish habit only when they walk out, or go to church. This at present consists of the *basquina*, or black petticoat, which is sometimes ornamented with gold embroidery, and trimmed with coloured ribands; the *mantela*, a broad black veil hanging from the head over the shoulders, and crossed on the breast like a shawl; and a showy fan, which is indispensable in all seasons, both in and out of doors. This instrument is of singular utility to the ladies; and "an Andalusian woman," says the author of Dobledo's Letters, "might as well want her tongue as her fan. The fan, besides, has this advantage over the natural organ of speech, that it conveys thought to a greater distance. A gentle tap commands the attention of the careless, a waving motion calls the distant. A certain twirl between the fingers betrays doubt or anxiety, a quick closing and displaying the folds indicates eagerness or joy. In perfect combination with the expressive features of my countrywomen, the fan is a magic wand, whose power is more easily felt than described."

The peasantry still preserve a diversity of dress in different provinces, but the common dress among them is a dark-coloured frock strapped round the waist, short breeches, with neither buttons nor gaiters, and a large round hat, or a *montera*, which is a cap of woollen or leather, sometimes round, and sometimes pointed at the top.

The usages and customs of this people have a reference in general to the national religion, and almost all their actions are blended with some superstitious observance. Every one has his patron saint to whom he applies on any emergency. The bed of an invalid is covered over with relics, amulets, and pictures; and a lady near her confinement is often wrapt in the episcopal robes of some saint, which are supposed to act most effectually when in contact with the body of the distressed petitioner. Their very names are derived from the same source; and it is a general notion among them, which is encouraged by the priests, that as many saints as have their names given to a child at baptism, are in some degree engaged to take it under their protection. Few have less than half-a-dozen names entered in the parish register, and many of them double that number. Their devotion to the Virgin Mary, who has innumerable images and titles in this country, furnishes them with a considerable variety. Almost every other Spaniard has Maria for a second name; and the most common names among the females are Encarnacion, Concepcion, Natividad, Esperanza, &c.

It used to be a common practice among the Spaniards to make pilgrimages to the shrines of their most celebrated saints, as St. James of Compostella in Galicia, our Lady of Guadeloupe in Estremadura, our Lady of Montserrat in Catalonia, and our Lady of the Pillar in Aragon. This custom, however, has fallen much into disuse, as also that of making short journeys to celebrated chapels and hermitages on the eve of the festival of the patron saint. The promiscuous crowd, assembled on these occasions, often spent the night in the most irreverent and dissolute revelries; and it was on account of the impieties which were there committed that the practice has been almost generally abolished. A few pilgrims still remain, but they are mostly strangers; and when persons of rank and opulence make a vow to beg alms, "they travel," says Laborde, "with every convenience, dismount from their carriage at the entrance of every town and village, beg through the streets, give away all that they receive to the poor, and then get into their carriage again and continue ther pilgrimage."

Religion with this people is rather a business than a feeling, and their devotion consists merely in external ceremonies, to which they are so habituated as to perform them almost instinctively, and the neglect of which would expose them to the horrors of the inquisition. In populous towns the inhabitants are frequently thrown into devotional attitudes by the sound of the little bell which precedes the priest who is carrying the consecrated wafer to a dying person. Its sound operates upon a Spaniard like magic. In whatever company or situation, in the street or in the house, he throws himself upon his knees, and in this posture he remains until the tinkling dies away in the distance. In the midst of a gay and noisy party, this sound brings every one to his devotions; if at dinner, he must leave the table, and if in bed he must at least sit up. Even in the public theatres, as soon as the bell is heard, "Dios, Dios," resounds from all parts of the house, and every one falls that moment upon his knees. The actor's ranting, or the rattling of the castanets in the *fandango*, is hushed for a few minutes, till the sound of the bell growing fainter and fainter, the amusement is resumed, and the devout performers are once more upon their legs, anxious to make amends for the interruption."

The Spaniards are very fond of public walks, and almost every town has its *alameda* or promenade, where the better classes assemble in the afternoon. Their chief amusement here, however, is not to walk, but to sit upon the stone benches, and take a view of the surrounding objects, or to carry on a whispering conversation with the next lady, which is termed in the idiom of the country *pelar la Pava*, "to pluck the hen turkey." Dinner parties are extremely rare, and only when an extraordinary occurrence happens in the family, as that of a young man performing his first mass, or a daughter taking the veil. On these occasions the dinner is always brought ready dressed from the coffee-house; and even then they never sit at table after the desert, but every one goes home or retires to his chamber to take his *siesta*. Evening parties for cards and conversation, which they call *Tertulia*, are very common, and often numerously attended, and which generally conclude with a light supper. There is little ceremony in these parties, every one entering and retiring as it suits his convenience or his humour. Smoking has become very prevalent among all classes, even the ladies freely partake of it; and a Spaniard is seldom seen without his cigar—in the streets or public walks, in coffee-houses, at cards, or even at a ball. As these cigars are very expensive, the poor inhabitants make imitations of them by rolling up bruised tobacco in paper cylinders. Their ideas on this subject are not the most delicate; for sometimes a smoker presents his cigar to his neighbour, who passes it on to the rest, and thus all use it in turn. Mr. Townsend mentions the circumstance of a tradesman of Luanjo having lighted his cigar, began to smoke, and finding it work well, presented it to the Countess of Penalba. She bowed and took it, smoked it half out, and restored it to him again; but as the Asturians consider smoking to be of no use unless the smoke passes through the lungs, a few minutes after she had joined the conversation, she opened her mouth and sent out a cloud of smoke.

The Spaniards are greatly attached to their national spectacles and public festivals. These festivals, however, are differently celebrated in different parts of the country. They are brilliant and magnificent in the provinces of Aragon, Valencia, and Catalonia; but simple and unostentatious in the other provinces. In the latter processions are very rare, but in the former they are very frequent, and performed with great pomp and preparation. The principal of these festivals are, the Carnival, Holy Thursday, Good Friday, Corpus Christi, St. John's Eve, &c. It would be tedious and difficult to describe all that passes at these festivals. The streets and squares are crowded from sun-rise to midnight. Business is completely neglected; and the spirit of devotion, which prevails in the morning, is converted by the shades of night into that of intrigue and licentiousness. There is on such occasions little fear of their evil practices being discovered. They are surrounded by multitudes who have the same intentions, and therefore indulgence is reciprocal. But the great national spectacle of Spain is the *bull fight*. This amusement was at one time suppressed by order of the government; and the prohibition continued for several years. This favourite spectacle, however, was again granted to the wishes of the people in 1799: and "the news of the most decisive victory," says Dobledo, "could not have more elated the spirits of the Andalusians, or roused them into greater activity." But for a description of this spectacle, we must refer our readers to the article Bull-fights in this work.

The shadow of ancient chivalry still exists, in some part of Spain, in those festivals called *parijas*, which are given by the *maestranzas* of Valencia, Granada, Seville, &c. The maestranza is a body of nobility, commanded by a lieutenant, who is usually a prince of the blood, and is elected every year; and is divided into four companies, each under the command of a knight. Every member, before admission into this corps, must prove a descent of four degrees. Three feasts are given every year on the birth days of the king, queen, and the prince who is at the head of the particular maestranza; and the whole expense is defrayed by the lieutenant. On these occasions they perform a variety of military evolutions, which are executed with great exactness. They also run at the ring, engage in sham-fights, dart their lances, and throw balls made of spongy earth. These imperfect representations of the ancient tournaments often terminate the amusements of the court before leaving Aranjuez. Mr. Townsend saw one of these parijas at Aranjuez in 1786, in which "the prince of Asturias, with his two brothers, the infants Don Gabriel and Don Antonio, attended by five and forty of the first nobility, all in the ancient Spanish dress, and mounted on high-bred Andalusian horses, performed a variety of evolutions to the sound of trumpets and French horns; forming four squadrons, distinguished from each other by the colour of their dresses, which were red, blue, yellow, and green; they executed this figured dance with great exactness, and made an elegant appearance."

Chap. VI.—*Government—Laws—Administration of Justice—Finances—Army—Navy—Military Orders.*

Before the union of the crowns of Castile and Aragon, each of these kingdoms possessed constitutions extremely favourable to liberty. Their assembly of the states or Cortes, which were composed of the clergy, the grandees, the nobles, and the commons, or representatives of cities and towns, enjoyed many privileges well calculated to restrain the authority of the sovereign. In Castile the four different orders met and deliberated as one collective body, and their decisions were regulated by the sentiments of the majority. In them alone resided the right of imposing taxes, of acknowledging the heirs of the crown, of enacting laws, and of redressing grievances; and in order to secure the assent of the king to such statutes and regulations as related to the public welfare, it was usual to grant no supplies till such business was concluded. "There was not any body of nobility in Europe," says Dr. Robertson, "more distinguished for independence of spirit, haughtiness of deportment, and bold pretensions, than that of Castile. The history of that monarchy affords the most striking examples of the vigilance with which they observed, and of the vigour with which they opposed, every measure of their kings that tended to encroach on their jurisdiction, to diminish their dignity, or to abridge their power. Even in their ordinary intercourse with their monarchs, they preserved such a consciousness of their rank, that the nobles of the first order claimed it as a privilege to be covered in the royal presence, and approaching their sovereigns rather as equals than as subjects."

The constitution of Aragon, however, had some peculiarities, which distinguished it from that of Castile. Though the form of its government was monarchical, its genius and maxims were purely republican; and its laws had a reference to the monarch as well as to the lowest subject, the infraction of which might cost him his crown. The following compact, entered into between the states and the king on his accession to the throne, shows what were their ideas of the submission of subjects, and in which an opening was evidently left for rebellion: "We who are equal to you, and who have more power than you, make you our king, upon condition that you do not infringe our privileges; if not, NOT." The cortes of Aragon was composed of the same number of orders, and endowed with similar privileges as that of Castile; but no law could pass without the assent of every single member who had a right to vote. This court was assembled on four different occasions: 1st, On the accession of the king to the throne, to do homage to him, and to administer the oath: 2dly, To deliberate upon the supplies and services which they ought to afford him when they were necessary; 3dly, To agree to the establishment, alteration, or suppression of laws; and, 4thly, to debate upon the taxes, tributes, and duties that they should allow the prince. After the cortes was called together, the king had no right to prorogue or dissolve it without its own consent, and the session continued forty days. This body exercised powers, unknown in any other kingly government. They claimed the privilege of nominating the members of the king's council, and the officers of his household; and of appointing officers to command the troops raised by their authority. Their exertions, however, were not confined merely to the upholding of their own privileges, and maintaining the freedom of the constitution, but they were equally solicitous in securing the personal rights of individuals; and in 1335 they abolished the practice of torture, which was then permitted by the laws of every other nation in Europe. The same spirit prevailed among the people in 1485, when an attempt was made by Ferdinand and Isabella to introduce the inquisition into Aragon, they took up arms, put to death the chief inquisitor, and long opposed the establishment of that horrid tribunal. So jealous were the Aragonese of their freedom, that, not willing to commit the sole guardianship of their liberties to the vigilance and power of the Cortes, they had recourse to an institution peculiar to themselves. They elected a *Justicia-mayor*, or supreme judge, whose office bore some resemblance to that of the Ephori in ancient Sparta; and who acted as a judge between the king and the nation—moderating the authority of the monarch, and defending the rights of the people. The person of this magistrate was sacred, his power and jurisdiction almost unbounded, and he was responsible to the Cortes only for the manner in which he discharged the duties of his high office. "The attachment of the Aragonese to this singular constitution of government was extreme, and their respect for it approached to superstitious veneration. In the preamble to one of their laws, they declare that such was the barrenness of their country, and the poverty of its inhabitants, that if it were not on account of the liberties by which they were distinguished from other nations, the people would abandon it, and go in quest of a settlement to some more fruitful region."

The peculiar privileges of the two kingdoms of Castile and Aragon continued to exist long after their reunion; but, in the beginning of the 16th century, the princes of the house of Austria began to take umbrage at their exercise; and, while they dared not openly attack them, they had recourse to the more effectual method of secretly undermining them; and thus were so far diminished, that, at the conclusion of the 17th century, they were little more than mere forms. In Castile the nobles had been formally excluded from the legislative assembly in 1538, by which step the privileges of the commons were virtually abolished; and though the states-general in this kingdom continued to form a part of the constitution, their convocation was reduced to a vain ceremony; and before the invasion of Spain by Bonaparte, they had not been assembled for more than a century. Philip V. suppressed the states-general of Aragon in 1720.

At present the government of Spain is an absolute monarchy, the whole authority centering in the king and his ministers. These ministers, and also the members of the different councils which conduct the national affairs, are appointed by the crown, and are removable at pleasure. There are five ministers of state, viz. the minister for foreign affairs; the minister for administering justice, and dispensing favours; the minister of war; the minister for conducting the business of the navy; and the minister of finance. Connected with these are five councils: *The council of Castile*, which possesses both legislative and executive powers, and exercises the double function of advising the king, and administering justice. Its decrees are decisive in the courts, but its judgments are under the control of the king: *The Royal and supreme council of the Indies*, which is invested with the same powers, and exercises similar functions for the colonies, as the former does for the continent of Spain: *The supreme council of war*, which conducts every thing relating to military concerns: *The royal council of finance;* and *the royal council of orders*. The council of state, or privy council, which, at its institution, consisted of the king's confidential advisers, has for a century past, been merely an honorary association, and serves at present only to recompense such persons as the king wishes to distinguish by conferring on them the high honours and appointments attached to the title of a counsellor of state. All the most important offices are filled by men taken from the lower ranks of society. The grandees, satisfied with hereditary wealth and honours, have no objection to partake of the splendours of the throne, or to bask in the sunshine of royal favour; but shrink from the drudgery and responsibility of official situations; and such is the general neglect of education in this country, that the ministers find it difficult to obtain proper persons to fill the common offices.

The common law of Spain has undergone various modifications. The code established by the Romans was abrogated by the Goths; and theirs in their turn was abolished by the Saracens. During the re-conquest of Spain by the Christian princes, many different systems sprung up in the various small kingdoms into which the country was divided; and upon its final recovery to Christendom, each of these was governed by its own peculiar laws, which were, in general, a mixture of Roman and Gothic law, with some particular usages and local statutes. Upon the union of the different independent states under Ferdinand and Isabella, these sovereigns established some new laws under the title of *Ordenamiento real:* and in 1505 the states of Castile published a new code, which became the established code of that kingdom, and afterwards of all Spain, except Navarre and Biscay, which still retain their ancient laws and constitution. The laws, by which justice is at present administered in Spain, are contained in the codes known by the following titles: *Fuero juzgo*; *Ley de las siete partidas*; *Ordenamiento real*; *Fuero real*; and *Recopilacion*, which last is a collection of occasional edicts of the kings of Spain, and enjoys very high authority.

The tribunals of justice are sufficiently numerous. Every city, town, or village has its corregidor or alcalde, who exercise their jurisdiction within a certain extent of district. They have also the superintendence of the police in the places where they reside, and are the official presidents of the municipal body. These magistrates are nominated by the king, and take cognizance of all causes whatever that occur within their particular districts, except such as belong to the *Tribunals of Exception*, which will be afterwards noticed. In the principal cities, which are at once the centre of a corregidorate, and the residence of a military governor, the two offices are united, and the administration of justice is committed to the superior alcalde; the former being entrusted with the command of the military force, the immediate execution of the orders of the court, the regulation of the markets, the price of commodities, and with all that relates to the billeting and expediting the march of troops; and to the latter, it belongs to determine in all suits of law, whether civil or criminal. From the decision of the inferior courts, appeals are carried to the *Royal Audiences*, of which there are seven, namely, that of Galicia at Corunna, that of Seville, that of Asturias at Oviedo, that of Aragon at Saragossa, that of Valencia, that of Catalonia at Barcelona, and that of Estremadura at Cacerez. These tribunals take cognizance of all matters of police, and of appeals from the sentences or judgments of the lower courts. In criminal cases their sentence is final; but in civil suits their decision is absolute only when the object of litigation does not exceed 10,000 maravedis, about three pounds sterling, when an appeal lies to one of the *Chanceries*, or to the Council of Castile. There are only two Chanceries, one at Valladolid, which comprehends within its jurisdiction all the territory of Spain lying beyond the right bank of the Tagus; and the other at Granada, which includes the country beyond the left bank of the same river, except the kingdom of Navarre, which having retained a considerable portion of its ancient privileges, possesses a royal council at Pampeluna, which judges definitively without allowing farther appeal to any of the audiences or chanceries. The chanceries, besides receiving appeals from decisions made by the courts of audience, take cognizance of all civil and criminal causes that occur within five leagues of the cities wherein they are established; also of all causes in which the royal household is concerned, or in which the corregidors, alcaldes, and other officers of justice, are personally interested as plaintiffs or defendants; also of all questions relative to the privileges of the nobles, and the recognition and maintenance of nobility." From their sentence there is no appeal, unless it be in a civil suit involving property to the amount of 5000 gold doubloons (£10,000) and upwards, when a petition is presented within twenty days to the king, who refers the final decision of the cause to the Council of Castile. This council, as it regards its judicial capacity, is the supreme tribunal of the state, and before it all sentences pronounced by the superior courts may be brought for revision. For the better despatch of business, it is divided into five chambers or committees; two chambers of government, the chamber of fifteen hundred, the chamber of justice, and the chamber of the provinces. Each of these has its own department of business, taking cognizance only of causes of a particular description.

Besides these various courts of judicature, there are others of a very peculiar nature, generally called *Tribunals of Exception*, and which are so very numerous that at least half the business of the kingdom is withdrawn from the ordinary tribunals. The principal of these, besides the military courts, the ecclesiastical courts, and the fifteen courts of the inquisition, are, the *Court of general superintendence of rural affairs, and of successions in cases of intestacy*; the *Court of Prato Medica*, which takes cognizance of affairs relative to medical, surgical, and pharmaceutical police; the *Court of the Mesta*, which has been already alluded to; the *Court of general direction and superintendence of couriers, posts, inns, roads, and canals*; the *Real Junta de Obras y bosques*, which has the superintendence of the forests, fisheries, chases, parks, and palaces of the king: the *Court of Alcaldes de Corte*, or of the royal household, which is intrusted with the police of the capital, and whose jurisdiction also extends to every place where the king and his household actually reside. There are also four courts of exception relative to particular branches of the royal revenue; and *Consulates* in the principal commercial towns,, which take cognizance of disputes between the buyer and seller of mercantile produce.

Notwithstanding, however, this multiplicity of tribunals, justice is very badly administered in this kingdom. The facility of appeal from one court to another renders law-suits both tedious and expensive; and the circumstance, that the losing party, however unjust his claim, or however weak his defence, is scarcely ever obliged to pay his adversary's costs, puts it in the power of the rich to oppress and ruin those who are unable to support the expenses of a law-suit, which in Spain are enormous. But the greatest evil of all arises from the oppression and misconduct of the provincial judges, who are frequently influenced in their decisions by mercenary views. Their venality is so notorious, and their power so great, that to complain would be dangerous, and therefore every citizen is anxious to secure the favour and protection of a corregidor or alcalde as the only means of safety for his person and his property. Mr. Townsend mentions several instances of the rapacity of these magistrates. A military governor, who was much favoured by the king, when new in office, refused taking bribes, and ruled his rapacious officers with a rod of iron, but soon became infected with the love of money, and received it upon the most infamous occasions without a blush. Under his protection merchants defrauded the revenue, and bankrupts found shelter from their creditors. Another magistrate, having promised, for a bribe of one hundred dollars, not to grant an attachment to a person, who had pretensions to some property, yet granted it, and being reproached for his conduct, he replied with coldness, "How could I avoid it, when he gave me forty dollars; but be not uneasy, for to-morrow I will take off the attachment."

When such abuses prevail we may be certain that the government is vicious, that the laws are weak, and that violence has usurped the throne of equity.

The revenues of the kingdom of Old Spain are derived from various sources, and are classed under the following heads.—1*st*, *Personal Revenues of the Sovereign*, which comprise the produce of certain crown lands; the grand masterships of the four military orders, which were annexed to the crown by Ferdinand V.; the pasturage of the Serena, in Estremadura; the national or royal lottery; the produce of the mines, which are wrought on the king's account; the effects of clergymen dying intestate, and some other rights of minor consideration.—2*d*, *Rights of Chancery*, which include the droits arising from letters of naturalization, and dispensations respecting age, impediments, and illegitimacy; letters patent for erecting or restoring the rank of peerage, which, in the former case, costs forty thousand reals, and in the latter varies from twenty to forty thousand; fines levied upon all who succeed to rank or title; the annual fines called *lanzas*, paid in lieu of military service, and levied upon all who bear the title of duke, marquis, earl, or viscount, except some few who have obtained special dispensations; fines upon all employments and situations filled by royal nomination, and upon the admission of physicians, counsellors, &c. 3*d*, *General Rents*, which comprehend the revenue of the post office; duties upon imports and exports; premiums paid for licenses to ships trading to America; and taxes on tobacco, salt, lead, playing cards, quicksilver, stamped paper, sealing wax, gunpowder, and sulphur. 4*th*, *Provincial Rents*, which include the *Alcavalas*, which is a tax upon every article sold or bartered, whether belonging to agriculture, trade, or manufactures, and is paid every time the property is transferred, at the rate of two per cent. *ad valorem*, for home produce, and articles manufactured in Spain, and fifteen per cent. for those brought from foreign countries; the *alcavala y cientos*, which is similar to the last, and is a duty upon moveables and immoveables, every time they are exchanged or sold; it varies in different provinces and cities according to their respective privileges, but the average is from six to seven per cent. *ad valorem*. These are the most grinding of any description of taxes, and fall heavier upon the lower orders, who, from their scanty means of subsistence, are obliged to purchase from a fourth or fifth hand, and who consequently must pay this duty an equal number of times over; while the rich, who can buy by wholesale, and of the first supplies of the market, pay it only once. Their collection also gives rise to many vexatious proceedings on the part of the subordinate officers of excise, whose dishonesty and covetousness are well known, and whose exactions it is difficult to satisfy. Owing to the inconvenience attending this branch of the revenue, Ferdinand VI. established a commission in 1749, which was empowered to consolidate all imposts of this description into one general tax; but this object still remains to be accomplished. 5*th*, *Local Taxes*, which embrace the duties upon a great variety of articles, as gold and silver coin, brandy, beer, wool, a per centage upon leases of land, &c. 6*th*, *Taxes peculiar to certain provinces*.—Biscay is subject to none of the preceding imposts, but pays its portion of taxation under the name of a benevolence, which is assessed upon the inhabitants without the interference of the officers of the crown; and the impost trade of Navarre pays no duty unless the articles are sent out of the province. None of the provincial rents extend to Catalonia, that province being subject to taxes peculiar to itself, namely, the tenth of the rent of houses, lands, tithes and mills; a similar tax upon the supposed gains of merchants and mechanics; a duty of eight and a-half per cent. upon labour, whether of artists, manufacturers, or day labourers; a poll-tax upon animals according to their size; a duty upon the sale of glass; and a tax in lieu of furnishing lodgings and provisions for the army. The provinces of Aragon and Valencia are freed from the duty of Alcavala, upon payment of a single contribution as an equivalent. This is assessed equally upon all kinds of property, and is very moderate. 7*th*, *Taxes upon the Clergy*, which consist of various imposts levied upon all ecclesiastical offices, and the revenues arising from vacant benefices, suppressed religious orders, &c. The amount of these different taxes for 1778 was as follows:

	Reals de Vellon.	*Mara.*
Class First	1[illegible],[illegible]22,9[illegible]9	16
Second	7,0[illegible],[illegible]96	25
Third	3[illegible]1,[illegible]25,[illegible]3	27
Fourth	122,857,13[illegible]	
Fifth	22[illegible],[illegible]36,461	12
Sixth	[illegible]1,1[illegible],[illegible]9	
Seventh	42,347,392	
Total	777,111,881	13

Before the South American states had raised the standard of independence, the king of Spain derived a considerable revenue from the two Indies. The produce of the mines with the alcavala, customs and duties upon various articles, yielded annually a gross revenue of 405,000,000 reals; but the expense of collection, and of the colonial government, absorbed nearly two-thirds of the whole amount, so that scarcely more than 140,000,000 reals arrived at the royal treasury.

Total Revenues of the Kingdom.

Revenues of the continent of Spain	777,111,831	13
Nett revenues of the colonies	140,000,000	0
	917,111,[illegible]1	13 reals,

which is equal to £9,553,218, 15s. 5¾d. Sterling.

We give the subjoined account from Laborde, as affording every necessary information respecting the receipts and disbursements of the government. It contains a statement of the sums lodged in the royal treasury, and payments made out of the same in 1791.

Receipts.	*Reals de Vellon.*	*Mara.*

Total,	800,488,687	17

Previous to the year 1747, the taxes were leased out or farmed, and consequently the abuses committed in the collection were numerous and grievous. The poor peasants were robbed and plundered with impunity, not merely by the farmers general, and those who rented under them, but by the judges, who, being bribed by the farmers, justified their oppression. The people reiterated their complaints from year to year; but the evil was never wholly removed until the Marquis de la Ensenada, the minister of Ferdinand VI. abolished the farms, and placed the collection of the taxes in the hands of administration. This plan, however, is very expensive, owing to the great number of tax-gatherers, which, besides the numerous guards, which are requisite to enforce payment, and to prevent smuggling, amount to nearly 28,000. The state of Spanish finances is so very complicated, that their collection is still every where attended with many harassing circumstances, and perplexing difficulties; and though numerous tribunals are attached to the different branches of revenue for the hearing of complaints, and the settlement of disputes, yet the people still suffer from the impositions and extortions of the collectors.

The national debt of Spain has been contracted at different periods. According to the Abbé Raynal, Charles V. alone, for the support of the rash and ruinous wars in which he was engaged, borrowed to the amount of 4,000,000,000 of reals, equal to £41,666,666, 13s. 4d. sterling. As the interest of this sum exceeded the whole revenue of the state, the government became bankrupt. Upon the accession of the Bourbon dynasty, public credit was again restored, and Philip V. taking advantage of this reviving confidence, contracted fresh engagements to the amount of nearly 700,000,000 reals. Ferdinand refused to discharge any debts contracted by his predecessors, and left his coffers replenished with 640,000,000 reals. Charles III. expended the half of this sum in the redemption of the debt, and the remainder in fruitless wars. Since that period additions have been made to it at different times, and also small portions of it redeemed; but in the beginning of the present century, it amounted to the very moderate sum of 1,800,000,000 reals, or £18,500,000 sterling. This debt consists of bills issued by government, which bear interest at 4 per cent. and are divided into *vales reales*, which are not in circulation, neither taken in payment of taxes, and *vales dinero*, which are payable at sight by the *casa de consolidacion*, or redemption board. Large portions of the debt have been redeemed by this board; but since the commencement of the peninsular war the redemption of the *vales* has entirely ceased: and when we consider the low state of credit at present in that unhappy country, it is not likely that it will soon be renewed.

The following table shows the amount of money raised in England for Spain from 1820 to 1823.

Year.	Amount of Capitals created.	Rate per cent. By contract.	Rate per cent. Per An.	Extreme Rates. Max	Extreme Rates. Min.	Amount of money raised by England.	Annual obligation.
1820	£3,000,000	47	5	10	74	3,820,000	700,000
1821	3,000,000			8½	73½		
1822	3,000,000	54		7	71	3,210,000	
1822	4,000,000			7	70¾		
1823	1,000,000	26		4	33	260,000	

When Philip V. ascended the throne of Spain, he had not a single ship fit for sea; and there were scarcely 15,000 troops in the whole kingdom. But no sooner was this monarch in quiet possession of the crown, than he directed his principal attention to the increasing of his army, and the establishment of military discipline. When Mr. Townsend visited Spain in 1787, the military establishments of every description were upon a very respectable footing. Since that time the army has been considerably augmented; and in 1798, the whole forces of the kingdom, including militia and invalids, amounted to 163,992 men, which consisted of the following description of troops:

	Officers.	Men.	Total.
1. *Army Staff.*			
General officers - -	560		
Inspectors, intendants, commissaries, &c. - - -	140		
	700		700
2. *King's Household Troops.*			
Life guards, 4 companies -	87	880	
Flying artillery, 1 ditto -	7	61	
Halberdiers, 1 ditto - - -	3	100	
Spanish guards, 6 battalions	171	4200	
Walloon guards, 6 ditto - -	171	4200	
Carabiniers, 4 squadrons -	51	600	
	490	10,041	10,531
3. *Horse Regiments.*			
Cavalry, 13 regiments of three squadrons each - - - -	364	5382	
———, 2 ditto, of 4 ditto -	74	1104	
Dragoons, 8 ditto of 5 ditto -	240	4416	
Chasseurs, 2 ditto of 5 ditto -	60	1104	
Hussars, 2 ditto of 5 ditto -	60	1104	
	798	13,110	13,908
4. *Infantry.*			
Spanish, 38 regiments of 3 battalions each - - - - -	2210	59538	
———, 10 ditto of 1 ditto -	280	6930	
Italian, 1 ditto - - -	58	1536	
Swiss, 6 ditto - - -	330	7658	
Artillery - - - - -	404	4400	
Engineers, with sappers and miners	150	1400	
Invalids, effective, 45 companies	137	3510	
———, ineffective, 26 ditto -	82	1820	
Militia, provincial, 42 battalions	1470	34340	
———, civic, 120 companies -	363	9317	
Provincial grenadiers, 4 regiments	120	2800	
	5604	133,249	138,853
Total - - - -			163,992

The Spanish troops are all distinguished by a red cockade, except the Walloon and Swiss guards; that of the former being red and black, and that of the latter red and yellow.

The pay of the infantry is fixed at the following sums per month, the *reals* being equal to 2½d. sterling.

		Foreign Infantry.
Commandant - -	1000	
Captain of grenadiers	800	- 600
Captain General - -	700	- 500
Lieutenant of Grenadiers	480	- 421
First Lieutenant - -	400	- 321
Second Lieutenant - -	320	- 301
Sub-Lieutenant - -	250	- 261
Private per day - -	1½	- 1½

The militia are raised only in the provinces belonging to the crown of Castile, the others being exempted from these levies. The provincial militia in times of peace are embodied one month in the year in the principal city of the department to which they belong, and receive the same pay as the infantry of the line. They are liable at an hour's notice to be called out upon actual service, and have frequently been most advantageously employed in defending the frontier, and in maintaining internal tranquillity. The civic militia neither receive pay, nor are liable to be called away from the particular stations to which they belong. They choose their own officers, and most of them have peculiar commandants.

Spain is divided into eleven grand military departments, viz. Old Castile; Aragon; Catalonia; Valencia, and Murcia; Navarre; Guipuscoa; Andalusia; the coast of Granada; Galicia; Estremadura; and Madrid. Each of these comprises several smaller divisions, which have an appointment of a larger or smaller staff. The chief command resides in the governor, who assumes the title of captain-general, to which the governor of Navarre adds that of viceroy. In general, these governors possess both civil and military powers, preside in the supreme courts, and have the sole management of the police.

The military character of the Spaniards, which shone so conspicuous in the 15th and 16th centuries, has now so completely degenerated that the government have great difficulty in raising the regular quota of troops, and none of the national regiments have their full complement of men. All classes have a natural repugnance to a military life. The lower ranks are in general grave and sober, attached to home, and have no relish for moving about from place to place. They, however, make excellent soldiers; and are seldom wanting in valour. The nobles have even a greater reluctance to the service; which, however, arises from a different cause. No person can arrive at the rank of an officer, without having previously served as a cadet in the same regiment; and, as the number of cadets in the cavalry and infantry are indefinite, their promotion is consequently so very slow, that they sometimes remain five or six years without rank. Serjeants are also promised promotion among all the different forces, except the artillery and the Spanish and Walloon guards, these regiments requiring every candidate for rank to exhibit some proofs of his alliance with nobility. These regulations, while they produce emulation among the privates to become serjeants, and among the serjeants to be promoted as officers, disgust the nobles, whose Spanish pride cannot endure to see officers of mean birth become their equals, and sometimes their superiors. The consequence of this is, that a great many officers, who have been elected from cadets, after a short time quit the service, while those raised from serjeants never retire: so that the regular army is commanded by officers principally, who have arrived at that rank from serjeants. In some instances the number amounts to a half, and in others to a third. At one period there were not four noblemen in all the troops of the Spanish monarchy.

The Spanish navy, in 1776, was so low, that it contained only 57 ships of 30 guns and upwards, besides small craft. In a few years, however, it advanced so rapidly, that in 1793 it was more than doubled, as appears in the subjoined statement.

70 Ships of the line, carrying from	112 to 54 guns.
46 Frigates	42 to 18
3 Corvettes . . .	20 to 18
16 Xebecs	36 to 14
13 Bylanders . . .	20 to 10
28 Brigantines	24 to 10

12 Ourques	40 to 20
4 Gallies	3
4 Galliots	3
3 Bomb-vessels	10
8 Packet-boats	
7 Goelettes	
2 Fireships	
216 Vessels in all.	

The marine department comprises the naval forces, the sea and port service, the arsenal service, the naval administration, hospitals, &c.

The naval forces consist of a marine staff, officers, cadet guards, engineers, artillery, and infantry, or marines, appropriated entirely to the service of the navy.

The sea and port service comprehends all persons employed about the shipping, both those who are actually employed, and those who are kept in reserve, but ready to act when their services may be required. The former includes the port captains and different orders of pilots, with a considerable number of seamen and boys. The latter consists of the registered seamen, amounting to above 60,000, who, during peace remain at their homes, but are subject to be summoned and employed at a moment's warning: the war commissaries, recorders, sub-delegates, &c. who are stationed at the different depots, and constitute courts for taking cognizance of all affairs relative to the registered seamen.

The arsenal service is carried on chiefly at Cadiz, Ferrol, and Carthagena, which are the three grand naval depots, at which a great number of persons are constantly employed, under the orders of an inspector-general of marine, and a general of engineers.

The naval administration is composed of the commissioners, superintendents, comptrollers, clerks, &c. belonging to the various marine departments.

The following is a general statement of the Spanish marine:

Naval forces in 1798	16,552
Sea and port service in 1792	64,363
Arsenal service	20,257
Naval administration	470
Hospitals	227
Total	101,869

The Spanish navy, however, was crippled in the last war with England: and the ships of the line will now scarcely exceed 50.

Spain has numerous establishments for the education of the youth intended for the army and navy. The principal military schools are at Cadiz, Barcelona, Zamora, and Segovia. The three first are chiefly designed for the instruction of such young men as are intended for the engineering department, though young officers of every description are admitted, and where are taught drawing, mathematics, engineering, and fortification. That of Segovia is confined entirely to the artillery. In 1796 a school was founded at Madrid for the benefit of the younger officers belonging to the corps of cosmographical engineers, and who are instructed in geometry, mathematics, geography, meteorology, and astronomy. Marine schools of different descriptions are established at the three naval stations, Cadiz, Ferrol, and Carthagena. Those appointed for the marine guards, into which only sons of gentlemen are admitted, have masters of mathematics, physics, gunnery, and manœuvre; and in those established for the naval artillery are taught those parts of mathematics which are essential to the artillery and pyrotechnic service, drawing, fortification, statics, hydraulics, hydrostatics, and aerometry. Nautical seminaries and schools of pilotage are distributed in various places along the coast.

The widows of all officers of the army above the rank of lieutenant are entitled to an annual pension; but the husband must have obtained the rank of captain previous to marriage. The fund, from which these pensions are paid, is not supplied by the state, but is derived from different sources: 1st, A sum of 6,000 doubloons, appropriated to the establishment: 2d, Twenty per cent. granted by the king from the revenues of vacant bishoprics: 3d, Half a month's pay from all officers upon promotion: 4th, Two per cent. upon all military appointments: and 5th, The effects of officers who die intestate and without natural heirs. The administration of these funds is conducted by an establishment at Madrid, called "The Mount of Piety."

The principal military orders of Spain are those of Calatrava, San Jago, Alcantara, and Montesa, which, at their original foundation, were intended for active service against the enemies of the faith, particularly the Moors, who then possessed a considerable portion of the Spanish territory: but, since the annexation of the grand masterships of these orders to the crown by Ferdinand V., they no longer constitute a peculiar description of the public force. To these orders are attached several valuable commanderies, amounting in all to 19,656,000 reals. Of these the lowest is 1260 reals and the highest 840,000. Besides knights, each order has also so many monks and nuns annexed to it, who are bound by particular vows. There are in all 10 houses containing 169 monks, and 11 convents with 136 nuns. The qualifications for admission into these military orders at present are, eight years of active service in the Spanish army, and proofs of nobility of four degrees on the side of both father and mother; but no knight can be appointed to a commandery unless he has taken the vow of combating the infidels, of fidelity towards the sovereign, and of conjugal chastity.

The other orders are those of the *Golden Fleece* and of *Charles III.* The first was founded by Philip the Good, Duke of Burgundy, and passed by succession to the Spanish crown upon the accession of the Austrian family. It is confined to fifty members, of whom the king is the sovereign chief; and has alone the disposal of the collars. About a third of these are at present in the possession of foreigners. The order of Charles III. was founded in 1771 by the king of that name, and is composed of sixty grand crosses, two hundred pensioned knights, and an indefinite number of others. The pensions of the knights, which are fixed at 4000 reals, are given to military men, to men of letters, to lawyers, to gentlemen, and to those employed in the ministerial departments. Besides these, we may mention the order of *Maria Louisa*, which was established in 1792 by Charles IV. in honour of his queen, in whom the grand mastership was vested. Ladies only are admitted, and the number is confined to thirty.

Chap. VII. *Religion—Ecclesiastical Division—Clergy—Literature—Language—Weights—Measures—and Monies.*

Strabo informs us that the ancient inhabitants of Spain adored a nameless God, of whom they formed no visible representation, and to whom they erected no temples, performing their simple rites in the open air, on the first night of every full moon. This simple worship, however, by the conquests of the Carthaginians and Romans, was exchanged for the superstitions and fables of Paganism; but these in their turn soon yielded to Christianity, which met with an early and welcome reception in this country; and from the first ages of the church, Spain furnished many martyrs to the faith. The introduction of Arianism by the Goths and Suevi occasioned many dissensions. While the natives adhered to the Roman Catholic creed, their conquerors were devoted to the heresy of Arius, and each party had their separate churches, bishops, and priests. An attempt was made in 579 to establish uniformity of religious faith and worship. But this was resisted by the Catholics, and was followed by a civil war with all its numberless evils. About ten years after, however, Ricaredo, king of the Goths, abjured the doctrines of Arius in a national assembly held at Toledo, when the whole of Spain was reunited to the Catholic church. From this period to the invasion of the Moors, the Spanish church was remarkable for the purity of its doctrine, and the efficacy of its discipline; and even under that people the Spaniards continued for a time to retain their religious establishments, and held several ecclesiastical councils. But they began insensibly to adopt the manners and customs of their conquerors, and their faith became at last a monstrous mixture of Islamism and Christianity, in which the leading tenets of each were undistinguishably confounded; and so completely was the Christian religion corrupted, and almost eradicated from these parts of Spain under the dominion of the Arabs, that on the reconquest of Seville in 1248 by Ferdinand III., and of Granada in 1492 by Ferdinand V., the slaves were the only Christians that could be found.

At present, the religion of Spain is strictly Roman Catholic; and, until the middle of the last century, the pope nominated to all benefices and dignities under ecclesiastical patronage if they became vacant in the months of January, February, April, May, July, August, October, and November; and at all times if the incumbent happened to die at Rome. He also levied a considerable revenue from benefices, universities, colleges, &c. All these privileges, however, were unwillingly ceded by Benedict VI. to Ferdinand VI. and his successors in 1753. But in this forced renunciation of his rights the pope retained two very important privileges, viz. the supreme administration of the *contentious jurisdiction* over all cases that are brought before the ecclesiastical tribunals, which is exercised by his nuncio, and the *court of nunciature* at Madrid; and the nomination, at all times of the year, to fifty-two of the best benefices, independent of the royal authority. The king, besides nominating to all benefices under the immediate patronage of the crown, now appoints also to those under ecclesiastical patronage, which fall vacant in any of the eight months above mentioned; and ecclesiastical patrons have the right of nomination only when the vacancy happens in any of the other four months. Lay patrons fill up vacancies under their nomination at whatever time of the year they happen; for neither the king nor the pope have ever been able successfully to infringe on their privileges. The influence of the papal court is consequently greatly reduced, having now no authority or jurisdiction in the temporal concerns of ecclesiastical benefices; and while very high respect is paid to the sovereign pontiff, his power is circumscribed within narrow limits.

Spain is divided into eight ecclesiastical provinces, over each of which presides an archbishop, with the rank of metropolitan; and these again are subdivided into forty-four dioceses, governed by bishops. The archbishoprics, with their revenues and suffragans, are stated in the following table.

Archbishoprics.	Revenues Sterling Money.	Suffragans.
Toledo	£125,000	Cuenga, Siguenza, Segovia, Osma, Valladolid, Cordova, Jaen, and Murcia, with two assistant bishops *in partibus infidelium*, the one residing at Toledo, and the other at Madrid.
Seville	34,375	Malaga, Cadiz, Ceuta, and the Canary isles.
Santiago	28,621	Avila, Salamanca, Astorga, Zamora, Ciudad Rodrigo, Tuy, Orense, Mondonedo, Lugo, Coria, Placencia, and Badajos.
Granada		Guadix and Almeria.
Burgos		Pampeluna, Tudela, Calahorra, Valencia, and Santander.
Tarragona	18,333	Barcelona, Gerona, Lerida, Vicq, Tortosa, Urgel, Solsona, and Iviza, in the Mediterranean.
Saragossa	25,208	Huesca, Balbastro, Jaca, Taracona, Albarrazin, and Teruel.
Valencia	32,083	Segorbia, Orihuela, and Majorca and Minorca.

The cities of Oviedo and Leon have likewise each an episcopal seat, independent of any metropolitan authority, being under the immediate jurisdiction of the pope.

There are in Spain fifty-eight cathedral chapters, and eighty-two collegiate chapters, and abbeys of different orders; and almost every religious order is to be found in this country The most numerous are the Franciscans, who have 610 convents and 19144 monks. The Spanish church, as may be seen from the princely revenues of the archbishops, is very richly endowed. Some of the bishops, and other dignitaries, have also very considerable incomes. The bishop of Murcia receives annually about L.20,833 sterling, and the bishop of Lerida L.10,000. The canonries are not less opulent in proportion, averaging between 100,000 and 40,000 reals; and the dignitaries of the chapters are still more richly beneficed. Some of the monastic orders also possess immense wealth; the Carthusians and Hieronymites in particular are proprietors of the greatest part of the districts that they inhabit, and the latter have a monastery at the Escurial, the revenue of which amounts to L.29,166 sterling. The following statement is drawn up from the enumeration of the Spanish clergy in 1768 and 1788, by which it appears that the number of the clergy had been very considerably diminished within the space of twenty years.

	In 1768.	In 1788.	Diminution.
Secular clergy - - -	66687	60240	6447
Subaltern ministers of the church	25248	15875	9373
Monks of 1925 convents -	56457	49270	7187
Nuns of 1081 convents - -	27665	22337	5328
Total - - -	176,057	147,722	28,335

Since 1788 the diminution of the clergy of Spain has been comparatively much greater. In many convents the religious of both sexes have been reunited, and many have become extinct by having been prohibited from receiving novices.

All the clergy of this country, both secular and regular, are amenable to no secular tribunal, either in civil or criminal cases. The church has tribunals of its own, whose jurisdiction is sufficiently ample, extending in certain circumstances even over the laity. The police of each diocese is entrusted entirely to the bishop, who generally has a prison within the boundaries of his own palace. From the diocesan courts an appeal lies to the metropolitan tribunal, and from thence to the court of nunciature at Madrid. The most dreaded tribunal, however, is the inquisition, which cannot be named by protestants but with horror and detestation. It was first established in this country by Ferdinand and Isabella in 1480; and there are now fifteen tribunals of this description in the different cities of Spain. Each of these has a department or district, within which alone it is allowed to exercise its functions; but the principal tribunal, and that on which all the others depend, is established at Madrid. The inquisition, however, which, at its first establishment, was intended for the special purpose of watching over the purity of the Christian faith, is now rather an engine of state-policy; and the objects of its notice are political principles, rather than religious opinions. We are told that it is no longer what it formerly was, that its sentences are now dictated by sentiments of mildness and peace; and that its prisoners, while in custody, are treated not merely with humanity, but enjoy every possible indulgence. But no change has taken place in the form and manner of its proceedings, which are always covered by impenetrable secrecy; and, though the light of knowledge and civilization, which has been diffused over Europe, may have taught even inquisitors humanity; yet, wherever inquisitorial power exists, it must be liable to abuse, and clemency must be merely accidental. Its name will always continue to be odious, however its influence may be diminished, or its constitution modified; and it is an engine of tyranny to which no free people will submit, and which every wise government will be anxious to abolish. See our article INQUISITION.

The Spanish clergy, either with respect to intellectual endowments or moral character, when compared with those of most nations of Europe, are far below mediocrity. Many of their dignitaries, however, are bright examples of charity, purity, and piety; and it is stated by Laborde that "whatever may be the rank of an ecclesiastic in the sacerdotal hierarchy, he never habitually absents himself from his proper place of residence, where he expends the revenue of his benefice in alms or public works." This author records several instances of the public spirit and beneficence of those venerable men. "The most beautiful aqueducts, fountains, and public walks in the cities, have been constructed at the expense of their bishops; from them also the poor have received the most effectual relief in times of scarcity, epidemic disease, and war. The bishop of Orense converted his episcopal palace into an alms-house, where were lodged and supported three hundred French ecclesiastics condemned to transportation during the furies of the revolution: the prelate himself took his place at their table, and refused to partake of any indulgence that he could not also procure for his guests; and the bishop of Cordova, during the scarcity of 1804, and for a long time afterwards, made a daily distribution of twelve hundred rations of bread to the poor inhabitants of his diocese." But our commendation must stop here, for few of the clergy, either secular or regular, think it necessary to imitate the virtues of their superiors.

The religious orders, in particular, are the most degraded and depraved. They may all be comprehended under two classes,—monks and friars,—of whom the author of Dobledo's Letters has given the following accurate and spirited description: "The distinguishing characters of the monks are wealth, ease, and indulgence; those of the friars, vulgarity, filth, and vice. Among the monks the Benedictines are at the top of the scale for learning and decency of manners, while the Hieronymites deservedly occupy the bottom. To the friars I am forced to apply the Spanish proverb, 'There is little to choose in a mangy flock.' The Franciscans, however, both from their multitude and their low habits of mendicity, may be held as the proper representatives of all that is most objectionable in the religious orders. The inveterate superstition which still supports these institutions among us, has lost, of late, its power to draw recruits to the cloister from the middle and higher classes. Few monks, and scarcely a friar can be found, who, by taking the cowl, has not escaped a life of menial toil. Boys of this rank of life are received as novices at the age of fourteen, and admitted after a year's probation, to the perpetual vows of obedience, poverty, and celibacy. Engagements so discordant with the first laws of human nature could hardly stand the test of time, even if they arose from the deepest feeling of enthusiasm. But this affection of the mind is seldom found in our convents. The year of noviciate is spent in learning the cant and gestures of the vilest hypocrisy, as well as in strengthening, by the example of the professed young friars, the original gross manners and vicious habits of the probationers. The result of such a system is but too visible. It is a common jest among the friars themselves, that in the act of taking the vows, when the superior of the convent draws the cowl over the head of the probationer, he uses the words *Tolle verecundiam*, 'Put off shame.' And indeed were the friars half so true to their profession as they are to this supposed injunction, the church of Rome would really teem with saints. Shameless in begging, they share the scanty meal of the labourer, and extort a portion of every product of the earth from the farmer. Shameless in conduct, they spread vice and demoralization among the lower classes, secure in the respect which is felt for their profession, that they may engage in a course of profligacy without any risk of exposure. When an instance of gross misconduct obtrudes itself upon the eyes of the public, every pious person thinks it his duty to hush up the report, and cast a veil on the transaction. Even the sword of justice is glanced aside from those consecrated criminals; and crimes of the blackest description were left unpunished during the reign of Charles III. from a fixed and avowed determination of that monarch not to inflict the punishment of death upon a priest."

The state of science and literature in Spain has been marked by different eras; but perhaps at no period has it been so fettered and degraded by the deadening influence of absolute despotism as at the commencement of the present century. This country, when subject to the Roman power, could boast of names still held sacred in the annals of knowledge. Seneca, the Philosopher, Pomponius Mela, Quinctilian, Lucan, Martial, Cornelius Balbus, &c. were natives of Spain, and even under the barbarous Visigoths a few were distinguished for their genius and their virtues. Upon the invasion of the Moors, however, when driven to the mountains of Asturias and Galicia, they for a time sunk into a state of powerless apathy. The very name of science was forgotten, and their priests could hardly read the services of the temple. But these invaders introduced a high degree of civilization, and united with the most romantic bravery a passionate love of science and the arts. As the basis of national happiness and improvement, public schools were established in almost every town, and colleges, with well selected libraries, were splendidly endowed in all the principal cities under their dominion. In these the sciences of geography, experimental philosophy, optics, botany, natural history, and geometry, were cultivated with great success. The Moors were the first great improvers of chemistry; they excelled in astronomy; they enriched the medical art which they had acquired from the writings of the Greeks, with many important discoveries; and to them we owe both the science of arithmetic, and the invention of those numerical characters, which have been adopted by all European nations. Their most renowned universities were those of Seville, Cordova, and Granada; and such was the reputation which they had acquired, that crowds of learned men from various countries resorted to Spain to study those sciences which were no where else taught so successfully. Among those distinguished foreigners were the famous Gerbert, afterwards Pope Sylvester II., Daniel Morley, Campano de Novare, and Gerard de Carmana. To this people also we are chiefly indebted for the treasures of Greek and Roman learning, which they collected and translated, and thus preserved this sacred deposit when it was lost to the rest of Europe. The works of many distinguished Arabian authors who flourished at this period, have been handed down to our times; and the illustrious names of Averroes and Avicenna will ever occupy a high rank in the annals of philosophy and medicine. The Spanish Arabs were, in short the bravest and most enlightened people of their age. Their learning, their industry, their generosity, were the admiration of all Europe; and such also was the noble confidence which they inspired, that many of the Christian princes in Spain sent their sons to be instructed in their schools, and called in their physicians in dangerous cases.

When the native Spaniards were restored to the quiet possession of their country, by the final expulsion of the Arab armies from the peninsula, they were fortunate in having a monarch who knew the value of learning, and who was anxious for its revival among his subjects. Many of them had studied under their Moorish conquerors; and by the munificent patronage of Ferdinand and Isabella they were the means of disseminating a taste for science and literature among their countrymen, who had long sacrificed every other kind of knowledge to that of the art of war. A spirit was thus excited, which being fostered and encouraged by succeeding princes, raised Spain, in the reign of Philip II. to a high rank among the civilized nations of Europe; and the period between the end of the fifteenth and the beginning of the seventeenth centuries, may well be considered as the golden age of Spanish learning. During this era flourished many eminent philosophers, historians and poets, whose fame added lustre to the age in which they lived, and whose names still continue to embellish the annals of their country. But the successors of Philip inherited neither his talents nor his love of learned men; and, though the impulse which the sciences had received from his protection and bounty continued to manifest its energy for several years, yet, when withdrawn from under the shade of royal favour, their progress became impeded, and their professors suspended their labours. Public disasters, arising from tedious and unsuccessful wars, also contributed to hasten their decay, and to direct the attention of the nation to other matters. From that time science and literature have been allowed to languish, neglected alike by the throne and the people; and though a few eminent and favoured geniuses have arisen during this inauspicious period as meteors in the midst of darkness, yet Spain has never been able to recover her celebrity as a learned nation, though the names of Lopez de Vega, Cervantes, Francisco Cernandes, Ulloa, Quevedo, Saavedra, Benedict Feyjoo, Anthony Augustine, Archbishop of Tarragona, called by *de Thou* "the lamp of Spain," Christopher Acuna, and Calderon, may well preserve her fame.

There were formerly twenty-four universities in Spain, but they are at present reduced to seventeen, and of these six only deserve the name:—Salamanca, Toledo, Saragossa, Valencia, Alcala, and Cervera. That of Salamanca is the most ancient, and was at one time the most celebrated in Europe. It was founded by Alphonso IX. about the beginning of the thirteenth century, and considerably enlarged by his grandson Ferdinand III. It consisted of twenty-five colleges, a library, and an hospital, called *del Estudio*, intended for the amelioration of poor scholars; and such was the high reputation which it enjoyed, that students flocked to it from all parts of Spain, and from foreign countries. Its celebrity continued for nearly three centuries, but as rival institutions sprung up it began to decline, and the number of its students, at the conclusion of the sixteenth century, had decreased from 15,000 to 7000. At present though the establishment is still unimpaired, and consists of sixty-one professors, yet its schools are almost deserted, there being seldom more than 1000 scholars. The university of Toledo has twenty-four professors, and 3000 students; that of Saragossa twenty-two professors, and 900 students; and that of Cervera forty-three professors and 900 students. None of these establishments are of any great repute; and the last is scarcely known beyond the boundaries of Catalonia. The university of Alcala, founded by Cardinal Ximenes, was once a splendid institution. It consists of thirty-one general professors, and thirteen colleges, each of which has its particular establishment of masters, and the students receive gratuitous support and instruction. Scarcely a vestige, however, of its ancient splendour remains, and the whole number of its scholars does not exceed 500. But the most popular university in Spain is that of Valencia. It has fifty-eight professors; two for latin grammer, one for poetry and oratory, two for Greek, one for Hebrew, six for philosophy, two for mathematics, one for mechanics and natural philosophy, one for astronomy, eleven for medicine, seven for civil law, five for the canon law, one for ecclesiastical discipline, and eighteen for theology. Yet even here the system of instruction is very imperfect and faulty. They have not yet escaped entirely from the philosophy of Aristotle, and the theology of Thomas Aquinas: and as late as 1793 there was neither a laboratory nor apparatus for exhibiting a single experiment in chemistry and natural philosophy.

Besides the universities, and the military and naval schools, which have been already mentioned, there are numerous other establishments for the education of youth. Every monastery almost has a school for theology and philosophy, which is open to the public. There are also many colleges independent of the universities: and several seminaries attached to episcopal sees, and under the direction of the bishops. But in all the system is radically defective. In what relates to scientific discoveries they are half a century behind: and they devote too much of their attention to subjects which have long since been abandoned by the rest of Europe. "Their schools of astronomy," says Laborde, "are destitute of instruments and observatories: their courses of natural philosophy are without experiments: their teachers of natural history are unfurnished with cabinets: their professors of anatomy give no demonstrations: their schools of chemistry are without laboratories and apparatus: and their libraries are destitute of modern books."

With regard to what is called *polite literature*, they have made greater advances: but the numerous restrictions laid upon the publication of national works, and upon the introduction of foreign books, cramp the energies of genius, and must retard in every state the progress of liberal ideas. Among the modern authors whose writings have done honour to Spain, and who, in spite of numerous obstacles arising from the oppressive measures of a corrupt court, and a bigoted priesthood, have endeavoured to uphold her falling fame, the names of Father Isla, Bayer, Campomanes, Larugo, and Jovillanos, will ever rank among those of the benefactors of their country.

The poetry of Spain is perhaps the department of literature which has gained least by modern improvements; for since the introduction of the Italian measures by Bascano and Garcilaso in the 16th century, her best poets have been merely servile imitators of Petrarch. The prolix and pompous style of the writers of that school, though sometimes exhibiting an ingenious and happy invention, with occasional flights of sublimity, bear evident marks of a confusion of ideas; and Don Ignatius de Luzano, who published an Art of Poetry in 1737, attributes the scarcity of good writers to "a certain haughtiness, which accounts it a degradation to submit to prescribed rules, and which mistakes for enthusiasm and inspiration, what is only the fruit of a bewildered imagination." Some poets, however, have arisen in the present day, who have endeavoured to emancipate themselves from the prevailing errors, and to correct the national taste. In this number may be ranked Yriarte, Melendez, Moratin, Quintana and Ariaza. Yet such is the almost complete destruction of the love of literature in this country, that their works are read and appreciated but by a few. The great bulk of the nation manifest no relish or desire for mental improvement. Books are little read: and all, who are not engaged in business, are occupied in their attendance upon the ladies, with whom nothing of this kind is heard of. "Years pass away," says the author of Dobledo's Letters, "without the publication of any original work. A compilation, entitled El Viagero Universal, and the translation of Guthrie's Grammar of Geography, are looked upon as efforts both of literary industry, and commercial enterprise. There exist two royal academies, one for the improvement of the Spanish language, the other for the advancement of national history. We owe to the former an ill-digested dictionary, with a very bad grammar; and to the latter some valuable discourses, and an incomplete geographical and historical dictionary. The Spanish academy has published a volume of prize essays and poems, the fruits of a very feeble competition, in which the poetry partakes largely of the servility of imitation, and the prose is generally stiff and affected. Our style, in fact, is at present quite unsettled, fluctuating between the wordy pomposity of our old writers, without their ease, and the epigrammatic conciseness of second-rate French writers, stripped of their sprightliness and graces. As long, however, as we are condemned to the dead silence in which the nation has been kept for centuries, there is little chance of fixing any standard of taste for Spanish eloquence."

The Spanish language is a compound of the Latin and Teutonic, with a small admixture of Arabic. When the country was divided into a variety of independent sovereignties, each kingdom had a dialect of its own. But since the union of the crowns, the dialect of Castile has become the general language of the whole monarchy, and is still called the Castilian language. It is spoken in its purest state in New Castile, especially in the ancient kingdom of Toledo, and is one of the finest of the European languages. "It is dignified, harmonious, energetic and expressive; and abounds in grand and sonorous expressions, which unite into measured periods, whose cadence is very agreeable to the ear. It is a language well adapted to poetry, but it also inclines to exaggeration: and its vehemence easily degenerates into bombast. Though naturally grave it easily admits of pleasantry. In the mouth of well educated men it is noble and expressive; lively and pointed in that of the common people; sweet, seductive, and persuasive when uttered by a female. Amongst the orators it is touching and imposing, though rather diffuse; at the bar and in the schools it is barbarous; and is spoken by those about the court in a concise and agreeable manner." In the other provinces its purity has suffered considerably from the introduction of foreign words and idioms. It is mixed with French in Navarre, Catalonia and Valencia; with Portuguese in Galicia; and with Arabic in Murcia and Andalusia. The Basque, which is still spoken in Biscay, is supposed to be the ancient language of that country, before the invasion of the Romans, and is mentioned by Strabo and Seneca. It has no analogy with any known tongue; and is preserved without alteration or corruption in the mountainous parts of Biscay. Though it appears harsh and coarse to those who do not understand it, yet it is said to be destitute neither of elegance nor expression.

The liberal arts in Spain have had the same periods of splendour and decline, as science and literature. The architecture of the 16th century is worthy of being compared with that of the Romans: and the bridges of Badajos and Toledo, with some of the public buildings of the latter city and Madrid, deserve the careful attention of the skilful observer. The famous Escurial, of which a description has been given in this work, belongs to the same age, and is called by the Spaniards, the eighth wonder of the world. This building astonishes by its great extent, and the magnificence of its execution, as much as by the repulsive appearance of its site and neighbourhood. Spain can also boast of some distinguished sculptors; but "of all the liberal arts," says Laborde, "painting is that which has been most cultivated in Spain, and in which its natives have best succeeded. The Spanish school is little known, and deserves to be more so; it holds a middle place between the Italian and Flemish scools: it is more natural than the first, more noble than the second, and participates in the beauties of both." In this department Spagnolet, whose name was Joseph de Ribera, and Bartholomew Murillo, are well known; and in more modern times, Antonio Raphael Mengs supported the credit of the Spanish school. But here also the efforts of genius have sunk under the black and noisome influence of Spanish bigotry and despotism; and while the present government, both civil and religious, of this country continues, Spain must remain the most wretched and degraded of European nations.

We shall conclude the statistics of this country in the words of Mr. Townsend, who was well acquainted with the national character, institutions, and resources of this people, and whose faithful and lively descriptions have been universally appreciated. "Should this people banish the inquisitors, and assert their freedom; should they, happy in possessing one of the richest countries upon earth, contract the bounds of their unwieldy empire; should they confine their views within the limits of their own peninsula, and cultivate the arts of peace; should they, to cherish industry, abolish the monastic orders, lessen the number of their festivals, establish an agrarian law, and strike off the fetters by which their commerce has been bound, considering the soil, the climate, the abundance of water, the natural productions, the rivers, the harbours, and the local situation, we may venture to affirm, that no country of the same extent would be more populous, more wealthy, or more powerful than Spain."

The weights and measures of Spain vary in almost every province, and occasion much trouble and perplexity in every kind of commercial relation. The standard measure of length is the royal foot, which is divided into 12 inches, and each of these into 12 lines, and is to the English foot as 153.41 to 144. The royal foot, however, is very little used, many provinces having their own peculiar foot. The foot of Catalonia measures 11 inches and $\frac{3}{4}$ths of a line of the royal foot, that of Valencia 11 inches, and $2\frac{1}{4}$ lines, and that of Castile 10 inches, and 4 lines.

Cloths and stuffs are measured in Catalonia by *canas*, and by *varas*, in other parts of the kingdom; the *cana* is divided into eight *pams*, and the *vara* into four; but the *pam* varies in different places.

The *pam* of Catalonia	= 7 in.	4 lines of the royal foot.	
Aragon	= 6	$7\frac{2}{3}$	
Valencia	= 8	4	
Castile	= 7	8	

In the provinces belonging to the crown of Castile, land is measured according to the following table:

2 varas	= 1 brass =	5 feet	1 in.	4 lines.
2 brasses	= 1 estadel =	10	2	8
400 estadales	= 1 fanega =	4.088	10	8
50 fanegas	= 1 ungada =	204.444	5	4
The fanega of Seville and Toledo is	=	5.111	1	4
Valencia only		1.250	0	0

In itinerary measure, the common league of Spain is equal to

	13.619 feet	7 in.	6 2-3 lines.
Ancient legal league	17 037	7	4
Present legal league	10.222	2	8
New league fixed in 1760	16.555	6	8

The measures of capacity, both dry and liquid, are also very various, differing very considerably both in size and denomination; but we have room only for the principal ones. Their relative value is shown by comparing them with the pound of 16 ounces.

In the kingdom of Castile corn is measured as follows:—

4 quartillos = 1 celemine	=	10 lbs.	$5\frac{1}{3}$ oz.
12 celemines = 1 fanega	=	124	0
12 fanegas = 1 cahiz	=	1528	0
The fanega of Asturias is	=	161	$5\frac{1}{3}$
of Granada	=	136	$5\frac{1}{2}$
of Biscay	=	131	$5\frac{3}{4}$
The cahiz of Valencia is	=	463	1
of Aragon	=	262	0

In oil measure the *aroba* of New Castile			
and Seville is	=	25	0
of Madrid	=	24	8
of Valencia	=	31	8
of Aragon	=	27	0
of Catalonia	=	22	12

In wine the cantara of New Castile			
and Seville is	=	34	2
of Madrid	=	48	0
of Asturias	=	39	3 3-5
of Valencia	=	26	4
The *olla* of Galicia	=	340	0
The *tormeaux* of Cadiz	=	1020	0
The charge of Aragon	=	420	0
of Catalonia	=	273	12

Every province has its own particular weights, but in the kingdom of Castile the pound generally consists of 16 ounces, and of 12 in the kingdom of Aragon.

The quintal of Castile is	=	100 lbs.	0 oz.
of Galicia	=	125	0
of Biscay	=	154	13
of Guipuscoa	=	105	$15\frac{7}{8}$
of Aragon	=	111	1 2-6
of Valencia	=	126	0
of Catalonia	=	91	0

The weights for gold and silver are the same almost throughout the whole of Spain, and are as follows:—

12 grains	=	1 tomina
6 tominas	=	1 ochava
8 ochavas	=	1 ounce
8 ounces	=	1 marc.

Owing, however, to the grains of Catalonia and Valencia being heavier than the grain of Castile, 100 marcs of Catalonia are equal to 116 marcs $5\frac{1}{3}$ oz. of Castile, and 100 marcs of Valencia are equal to $103\frac{1}{2}$ marcs of Castile.

The monies of Spain, like most countries are real and imaginary; the former used for the purpose of exchange, and the latter serving only for keeping accounts and striking bargains. The real monies, both gold and silver, at present in circulation, have been coined at three different periods. Those coined previous to 1772 consist of different sized pieces of metal, unequally cut, whose currency is only by weight. Those of more modern coinage bear the head of the king on one side, and on the other the arms of Spain; and are current throughout the whole kingdom. Several of the provinces, however, have both real and imaginary money peculiar to each. The denomination and value of the latest coinage is as follows:

			Sterling Money.		
Silver Money.		*Reals.*	*L.*	*s.*	*d.*
Real, real de vellon, or realito - - -	=	1	0	0	$2\frac{1}{2}$
Real de Plata - - - - - - -	=	2	0	0	5
Peceta, or real de a dos - - - -	=	4	0	0	10
Escudo - - - - - - - -	=	10	0	2	1
Duro, pezoduro, or real de a ocho -	=	20	0	4	2
Gold Money.					
Durito, escudo chico de oro, or veinteno de oro - - - - - - -	=	20	0	4	2
Escudo de oro, or doblon senzillo -	=	40	0	8	4
Doblon de oro - - - - - - -	=	80	0	16	8
Doblon de a quatre - - - - -	=	160	1	13	4
Doblon de a ocho, or onza de oro - -	=	320	3	6	8

Imaginary Money.		*Reals*	*Mara.*		*Sterling*	*Money.*	
Ducado de vellon - - - -	=	11	1	nearly	0	2	$3\frac{1}{2}$
Ducado de Plata nueva - -	=	16	17		0	3	$5\frac{1}{4}$
Ducado de Plata doble, or ducado de Plata de Antigua - -	=	20	25	nearly	0	4	$3\frac{3}{4}$
Pezo, pezo senzillo, or piastra	=	15	0		0	3	$1\frac{1}{2}$
Doblon - - - - - -	=	60	0		0	12	6

The smaller denominations of money are,

2 maravedis - - -	=	1 ochavo
2 ochavos - - - -	=	1 quarto
$8\frac{1}{2}$ quartos or 34 maravedis	=	1 real.

The monies peculiar to the provinces are chiefly fictitious: those that are not, are of small value. The *denier* of Valencia is equal to one *maravedi;* and the *denier* of Catalonia is equal to $1\frac{1}{2}$ *maravedi.*

There are three mints in the continent of Spain, at Madrid, Seville, and Segovia. At the latter place, however, only copper pieces are coined. The greatest part of the silver *duros* are imported from Mexico. All the business relative to the coinage is under the superintendence of a supreme court established at Madrid under the title of *Real junta de comercio, meneda, minas, &c.*

SPENSER, EDMUND, a celebrated English poet, was born in London in 1553. In 1569 he was a sizer in Pembroke College, Oxford. A love adventure with a lady, whom he has immortalised under the name of Rosalinda, is supposed to have been the origin of his "Shepherd's Complaint," which appeared in 1577. In 1580, he was secretary to Lord Grey of Wilton, Lord-deputy of Ireland; and in that capacity he exhibited great capacity for business. Having received from the crown a grant of 3000 acres out of the Desmond estates, he went to Ireland in 1587, and resided in Kilcolman Castle, where he was visited in 1589 by Sir Walter Raleigh. At this time he had written three books of the Fairy Queen, and accompanying Sir Walter to England, he published it in 1590, and dedicated it to Queen Elizabeth, who rewarded him with a pension of £50 per annum. In 1591, he returned to Ireland, where he married a young woman of humble degree. In 1596, he published a new edition of his Fairy Queen, with additional books.

In consequence of the rebellion which broke out in Ireland in 1598, he was compelled to take refuge with his wife in England. His house was burnt, and an infant is said to have perished in the flames. Thus reduced to indigence, he sunk under his misfortunes, and died in 1599 or 1600, and was buried at the expense of the Earl of Essex. Anne, Countess of Dorset, afterwards erected a monument to his memory.

The Fairy Queen, though obscure in its allegories, has always been considered as one of the finest poetical compositions in our language.

STADE, a town of Hanover, situated on the Schwinge, a tributary to the Elbe. Its chief public buildings are a town-hall, merchants' hall, gymnasium, two churches, containing handsome monuments, and an orphans' hospital. It has manufactures of hats, flannel, lace, and stockings. The different public offices for the provinces of Bremen and Verden are situated here. A packet sails daily for Hamburgh. Population 4800.

STADIUM, a measure of length in use among the ancient Greeks. M. le Chevalier Lapie considers that he has demonstrated that the length of a stadium is the 700th part of a degree; a result which was rejected by D'Anville, but adopted by M. Gosselin. M. Jomard has recently found that the length of the ancient cubit is between 523 and 524 millimetres. See Dr. Brewster's *Journal of Science*, No. xii. p. 372.

STAFFA, a small island in the Hebrides, on the west coast of Scotland, celebrated for its grand caverns and basaltic columns. It is situated in the parish of Kilninian and county of Argyle, about five leagues to the west of Mull, and three leagues from Icolmkill. It is of an irregular oval form, consisting of an elevated table land, terminating on all sides in precipices of various altitudes. It is about one mile long and half a mile broad. The loftiest cliffs, which are on the south-west of the island, are 144 feet high; and on the north it declines to a flat rocky shore, only a few feet raised above the sea, and where the landing place is situated.

The objects of interest in this island are *Fingal's* cave, *Mackinnon's* cave, and the *Boot* cave.

The cave of Fingal, which looks to the south-west, was first pointed out as an object of interest by Mr. Leach, an Irish gentleman, who visited the island in 1772. It was afterwards visited by Sir Joseph Banks, Dr. Von Troil, bishop of Linkoping, and M. St. Fond; and it is now frequented by crowds of visiters, who are carried thither by steam boats, which leave Glasgow in the summer season once every fortnight for the express purpose.

The opening of the cave into which the sea flows is perpendicular at the sides, and terminates above in something like a Gothic arch. The following are its dimensions, given chiefly by Sir Joseph Banks:

	Feet.	Inches.
Length of the cave from the rock without	237	6
According to others - - -	227	0
Do from the pitch of the arch - -	256	0
Breadth of the cave at the mouth* -	53	7
——— farther end -	20	0
Height of the arch at mouth - -	117	6
——— at the end - -	70	0
Depth of water at the mouth - -	18	0
——— end - - -	9	0
Height of the tallest columns on the right side of the entrance - - -	45	0
Other measures make their height only -	36	0
Height of pillars at the eastern side -	18	0
Height of the cave varies from - -	50	44

The sides of the cave consist, like the mouth of it, of basaltic columns, similar to those which we have already described in our articles GIANT'S CAUSEWAY, and FAIRHEAD. They are, generally speaking, perpendicular; but they have not that regularity which is given to them in the ordinary engravings of the cave. The roof of the cave varies in different places. A deep channel forms the ridge of the roof. On each side of this fissure towards the mouth of the cave, the roof is formed of minutely fractured rock, similar to the stratum incumbent on the columns; about the middle of the cave the roof is composed of the broken ends of columns, and at the inner end of the cave, a portion of each kind of rock enters into the formation of the roof. Calcareous spar formed by incrustation between the ends of the columns in the roof, render them more distinctly visible.

The cave is never entirely free of the sea; but the broken range of columns, which forms the extensive causeway, is continued on each side within it. This causeway is most perfect on the eastern side, and allows the visiter to pass over it to the farthest extremity, provided the state of the tide permits it; but on the western side, the columns terminate at a considerable distance from the end of the cave. "When we behold," says Dr. Von Troil, "the Cave of Fingal, we are forced to acknowledge that this piece of architecture, formed by nature, far surpasses that of the Louvre, that of St. Peter at Rome, all that remains of Palmyra and Pœstum, and all that the genius, the taste, and the luxury of the Greeks were capable of inventing."

Mackinnon's Cave, also called the Cormorant's Cave, is situated on the north side of the island, in the midst of a magnificent colonnade. When the sea is a quarter ebb, the height of the cave is 50 feet, and its breadth 48. Its length is 224 feet, and it has nearly the same height and breadth throughout, excepting at the end where the roof and walls approximate, and a pebbly beach is formed. The general effect of the cave is very fine, though, in point of symmetry and elegance, it is inferior to the Cave of Fingal.

The Boot Cave is situated farther to the east, and from its mouth being beset with rocks, it can only be entered in calm weather, and at high water. It is from 14 to 16 feet high above high water. Its breadth is 12 feet, and its length 150. The roof and sides are smooth, and resemble the gallery of a mine. But though small in size, its effect is very picturesque, from the great symmetry of the columnar range in that part of the face, beneath which it is situated.

A family used to reside on the island both summer and winter, but we believe they now quit it at the end of summer. For farther information respecting this island, see Pennant's *Tour in Scotland* 1790, containing Sir Joseph Banks' description of Staffa, which has been lately reprinted in Thomson's *Pleasure Tours in Scotland*, Dr. Von Troil's *Letters on Iceland*, St. Fond's *Tour in Scotland*, and Macculloch's *Description of the Western Islands*.

STAFFORD, a borough and market-town of England, and capital of the county of the same name. It is built on the north bank of the river Sow, about three miles from where it joins the Trent. Its form is that of an irregular ellipsis, the greatest breadth of which is from south-east to north-west. Formerly

* Other measurements make this breadth only 42 feet.

it was surrounded by a wall, and defended by a castle, some remains of which still exist: it had also four gates. It is a very ancient borough, having been incorporated by King John in the seventh year of his reign. Stafford is very pleasantly situated; the streets are in general well paved, and most of the houses are neatly and regularly built of stone, and roofed with slates. The principal streets are built in the form of a cross, and the two largest ones occupy the sides of the road from Newcastle-under-Line to Wolverhampton. It is 135 miles north-west from London, and 16 from Litchfield, in the same direction.

The public buildings are numerous. There are two churches, St. Mary's and St. Chad's. The former is a spacious building, in the form of a cross, and consists of a nave, two side aisles, a transept, and a chancel of three aisles, in the middle of which is a large octagonal tower, with eight bells and chimes. The church also possesses a good organ, and a very ancient font. There are several fine monuments, both ancient and modern, in this church, the most remarkable of which are, an altar tomb in honour of Lord Edward Aston of Tixal, and the Lady Ann, his wife; a monument to the memory of Sir Edward and Lady Aston, and one to Lady Barbara Crompton, wife to Sir Thomas Crompton, judge of the High Court of Admiralty in the reign of Queen Elizabeth. The other church, viz. that of St. Chad's, is a very ancient structure, with a fine tower, but not containing any thing worthy of particular notice. The other public buildings are, the County Hall, an extensive modern structure, 100 feet long in front, in which the assizes and quarter-sessions are held. The county infirmary is a plain and substantial edifice, built about the year 1772. The county gaol, which is opposite the infirmary, is a large and convenient modern building, with accommodation for 150 prisoners. The free school is an ancient edifice, founded by Edward the Sixth in 1550. Stafford contains a number of alms-houses, built for the accommodation of the indigent inhabitants of the town, each of which has a garden adjoining to it. Stafford is governed by a mayor, recorder, twelve aldermen, twenty common council men, a town clerk, two serjeants at mace, and other inferior officers. The principal manufactures are those of cloth, cutlery, shoes, and beer. The town enjoys a considerable trade with the neighbouring counties by means of its canal. Stafford returns two representatives to parliament. The right of election is vested in the mayor, aldermen, and burgesses, there being about 400 voters in all. In 1821, the population was 5736 of both sexes: the number of houses was 991; the number of families 1090; and the number of families employed in trade 712. See the *Beauties of England and Wales*, vol. xiii. p. 881.

STAFFORDSHIRE, an inland and central county of England. It is bounded on the north by Cheshire and Derbyshire, on the east by Leicestershire, on the west by Shropshire, and on the south by Warwickshire and Worcestershire. Its figure is that of an oblong, extending from north to south. Its utmost length from north-east to south-west is 60 miles, and its greatest breadth from east to west is 38 miles. It contains 1148 statute miles, or 734,720 acres, the greater part of which is arable. The civil divisions are five hundreds, one city, (Litchfield) three boroughs, and twenty-four market towns. Staffordshire is in the province of Canterbury, and, with the exception of a small portion in the diocese of Litchfield and Coventry, it contains 180 parishes, and is included in the archdeaconry of Stafford. The general appearance of the county varies extremely in the different districts: thus, the middle and southern parts, which consist of one level plain, only interrupted by a few inconsiderable elevations, present a remarkable contrast to the northern district, which is distinguished by desolate and unproductive hills, and by the general air of bleakness that pervades its scenery. In this district, which is called the moorlands, there are several hills of considerable height, of which Bunster and the Weever Hills are the highest; the latter are 1154 feet above the level of the sea. The general elevation of the moorlands above the southern districts, is between 100 and 200 yards. Although the appearance of the uplands is so desolate, yet there are some districts in the southern part of the county, on the banks of the rivers, which may vie with any other part of England in beauty of scenery, and luxuriance of vegetation, the most celebrated of which are the banks of the Dove, especially at Ilam, and the country between Litchfield and Stone.

Staffordshire contains almost every variety of soil, but the most prevalent are the strong clays, and the gravelly and sandy soils. There is very little calcareous soil, and no chalk. In the waste lands, there is abundance of peat, which, however, when drained is highly capable of improvement. The meadows, particularly those on the banks of the Trent, are rich and fertile. The climate of Staffordshire is decidedly wet and moist. The annual fall of rain is about 36 inches. In winter, a considerable quantity of snow falls on the moorlands, which may account for the coldness of that district.

The rivers of Staffordshire, most of which have their origin in the moorlands, are not of any great size, and none of them are navigable. Yet they are of inestimable value to the county, as they supply with water the numerous canals that intersect it. The principal rivers are the Trent, which is the third river in England, the Dove, the Stour, the Blythe, the Tame, and the Penk, which last are all tributaries of the Trent. The Trent has its source at Newpool, near Biddulph, on the borders of Cheshire; it enters Derbyshire at Burton, where it receives the Dove. While it flows through Staffordshire it is a bold and rapid stream, bearing some resemblance to the Thames. After flowing through Nottinghamshire and Lincolnshire, it empties itself into the Humber, about forty miles below Gainsborough, to which place it is navigable for vessels of considerable burthen. The Dove, which is the river in Staffordshire next in importance to the Trent, rises in the moorlands, and after running through the beautifully picturesque country called Dovedale, and receiving the Manifold and Hamps, it joins the Trent at Burton in Derbyshire. Staffordshire is better supplied with navigable canals than any other county of England, which amply compensate for the want of navigable rivers, which otherwise would be a serious loss to the commercial interest of the county. The Grand Trunk Canal, which was planned and carried through by the late celebrated engineer Mr. Brindley, unites the three ports of Liverpool, Bristol, and Hull. Its total length is about ninety-one miles; the fall of water on the northern side is about 326 feet, and on the southern side 316. In the former there are thirty-five locks, and in the latter forty; the usual breadth at the top is twenty-nine feet, and it is four and a half feet deep. The numerous branches of this canal serve to establish a regular communication between the principal sea-ports and the central districts, and also a ready mode of conveyance for those goods, the value of which, owing to their weight and bulk, would be more than counterbalanced by the expense attending the carriage by land. There are few lakes of any size in this county, but the largest is that of Aquelate, which is 1848 yards long, and 672 broad.

Staffordshire is remarkable both for the variety and the abundance of its mineral products. Coal exists in such abundance that more than 50,000 acres have been found to contain almost inexhaustible strata of coal, which vary in thickness from twenty-four to thirty-six feet. Iron ore is raised in considerable quantities in the coal mines; the strata of iron usually occurring under a stratum of coal. A remarkable species of coal called the peacock coal, owing to the circumstance of its exhibiting prismatic colours, is raised at Handly Green. Copper and lead also exist, although by no means in such abundance as the iron. The other products are ochre, freestone, limestone, gypsum, alabaster, marbles of different colours. A great variety of clays are dug up, which are of the greatest service, as they supply the potteries, which are the chief support of the county.

The manufactures of Staffordshire are as extensive as they are various. The working of metals is carried on to a great extent in the southern part of the county. At Wolverhampton a great quantity of the heavier sort of iron goods,besides locks, hinges, keys, steel chains, &c. Wednesbury furnishes guns, saws, hammers, edge tools, and almost every description of cast iron articles. Stafford produces a number of articles in the leather and cutlery trade. Walsal supplies bits, spurs, buckles, stirrups, and all the iron work required by saddlers. The potteries, which are carried on in the northern part of the county, have been long celebrated for the superior excellence of the earthenware they produce, which is exported to almost every part of Europe. They occupy an extent of ten square miles, in which there are several considerable towns. This district, which goes by the general name of the Potteries, although the most barren, is now the most populous and wealthy part of the county. These potteries owe all their celebrity to the skill and perseverance of the late famous Mr. Wedgewood, who by his judicious admixture of the various descriptions of clay with which the county abounds, brought the earthenware to its present state of perfection. At Stourbridge there are extensive manufactories of glass. A quantity of salt is obtained at Shirley Wick, and at Ingestrie, by boiling brine from natural springs. Burton has long been celebrated for its ale, and possesses manufactories for hats and cotton goods. At Tamworth there is a large establishment for printing calico. There are brass and copper works at Cheadle. At Leck a considerable quantity of silk goods of various descriptions are made.

The agricultural products of Staffordshire are chiefly wheat, barley, rye, oats, potatoes, and turnips; crops of flax, hemp, pease, beans and vetches are also raised. The grasses most in use are clover and trefoil, and several artificial grasses have been introduced of late.

The cattle of Staffordsire, which are of the long-horned breed, are reared in such numbers as to supply the whole county, and still to leave a considerable surplus for other markets. The sheep are of different breeds; but the new Leicesters are the most common. The black-faced sheep with horns are reared on the commons in the west of the county. At Cannock and Sutton Colfield there is a variety, bearing a strong resemblance to the South Down.

The breed in the eastern part of the moorlands are white-faced without horns, and having long combing wool.

The only Roman antiquities in Staffordshire are the Watling Street, and Ichnield military roads which pass through the county. There are also a few ancient encampments. There are few remains of the Saxons worthy of notice.

The parliamentary representatives are ten, two for the county, and two for each of the undermentioned towns, viz Litchfield, Stafford, Newcastle, and Tamworth.

The population, by the returns under the census of 1821, was 341,040: of whom the males were 177,668, and the females 169,372. The number of inhabited houses was 63,319, and of families, 68,780; out of these families, 18,285 were employed in agriculture, 42,435 in trade and manufactures, and 8060 in neither of these departments.

STAHL Ernest. See Chemistry.

STAMFORD or Stanford, a town of England in the county of Lincoln, is situated on the slope of a hill on the banks of the river Welland, which is crossed by a narrow and ancient stone bridge. The town is built in the form of a cross, its principal streets coinciding with the great north road and that which goes from Uppingham to Market Deeping. The houses are generally well built with stone and covered with slate. Stamford contains six parish churches, St. Michael's, St. Mary's, St. George's, All Saints, St. John the Baptist's, and St. Martin's. St. Michael's consists of a nave and choir with north and south aisles, and chancels, extending beyond the nave. In St. Mary's church there is a monument to Sir David Phillips, who distinguished himself in the battle of Bosworthfield. St. George's church is a large plain building with chancel, nave, north and south aisles, and a square embattled tower. All Saints is large and symmetrical, having a lofty and handsome embattled spire at the west end of the north aisle. The founder of it, Mr. John Brown, is interred in the north aisle. The church of St. John the Baptist contains some excellent specimens of stained glass. St. Martin's church is a large and handsome edifice, with a square pinnacled tower, and containing, among other monuments, one of Lord Burleigh. The other public buildings are the town hall, built in 1776, and having two handsome fronts, an elegant theatre recently erected, and a good assembly room. New shambles have been lately built. The schools in Stamford are Radcliffe's free school, Wells' school, the Blue Coat school, and a girls' school on Dr. Bell's plan. The charitable establishments in the town are numerous. The most opulent of them is that founded in the reign of Richard III. by William Brown, of whom there is an effigy in All Saints church. By the river Welland the neighbourhood is supplied with articles of foreign and coasting trade, and the inhabitants export malt and freestone. The town is governed by a mayor, a recorder, town clerk, 12 aldermen, and 24 capital burgesses. It returns two members to parliament, and the right of election is vested in about 500 voters. The practice of bull baiting is said to be still repeated here on the 13th of November. In 1821 the population was as follows:

Inhabited houses	892
Number of families	1038
Families in trade	663
Total population	5050

About a mile to the south-east of Stamford is Burleigh house, the seat of the Marquis of Exeter. See the *Beauties of England* vol. ix. p. 793, and Blore's *Account of the Public Schools and Hospitals, &c. in Stamford*, 1813.

STATIUS Surculus Papinius was born at Naples about A. D. 61, and died about A. D. 96. His works, which are extant, are his Sylvæ, a miscellaneous piece in five books, his Thebaid, an Epic Poem, on which his fame rests, and two books of an unfinished poem entitled Achilles. The best editions of the Thebaid are those of Caspar Barthius, 4to. 1664, and of Veenhuysen, Ludg. Bat. 8vo. 1671.

STAUROLITE. See Mineralogy, Index.

STEAM.

Steam is the name generally given to the visible vapour which is driven off from fluids or moist bodies by heat. It is most frequently applied, however, to denote *aqueous vapour*, or the vapour raised from water by ebullition.

When water, exposed to the pressure of the atmosphere, is heated to the temperature of 212°, globules of steam, composed of heat and water in a state of combination, are formed at the bottom of the vessel, and rising through the fluid, may be collected at its surface. In its perfect state it is transparent, and consequently invisible, but when it has been deprived of a part of its heat by coming in contact with cold air, it becomes vesicular and of a cloudy appearance, as when it issues from a tea-kettle.

By increasing the heat, the temperature of the water never rises above 212°, nor that of the steam which is generated; the only effect being a more copious production of vapour. But if the water is confined in a strong copper vessel, both it and the steam which is produced may be brought to any temperature.

Like all gaseous fluids, steam is highly elastic; but if it is separated from the fluid from which it is generated, it does not possess a greater elastic force than the same quantity of air. If, for instance, a copper vessel is filled with steam only, at 212°, it may be brought even to the temperature of red heat, without any danger of bursting; but if water is also in the vessel, each additional quantity of caloric causes a fresh quantity of steam to rise, which adds its elastic force to that of the steam already generated till the constantly accumulating force bursts the vessel in pieces.

The latent heat of steam,* according to the experiments of different philosophers, is given in the following table:

Rumford	1021°	Watt	950° or 960°
Thomson	1016	Southern	945
Lavoisier	1000	Black	800
Clement	990		

The mean of these results is 950° agreeing with the measure obtained by Mr. Watt.

Since steam therefore of the temperature of 212° contains 900° of heat, which is not detected by the thermometer, while it retains the gaseous state, its real quantity of heat will be $950°+212°=1162°$; consequently, if we mix a quantity of steam with $5\frac{1}{2}$ times its weight of water, at 32°, the temperature of the water will rise nearly to the temperature of ebullition, because $5\frac{1}{2}\times 32°+32°=208°$. Hence the great utility of steam not only in manufactures where great quantities of hot water are required, but also for heating large buildings, and for drying whatever is liable to combustion.

The elasticity of steam, arising, no doubt, from the great quantity of heat which it contains, is very great, and from its extensive application as an impelling power, it has been investigated with considerable attention.

Mr. Watt was the first philosopher who made any accurate experiments on the elasticity of steam. The following account of them which Mr. Watt drew up at the request of the editor of this work, for his edition of Dr. Robison's System of Mechanical Philosophy, is as follows:—

"In the winter 1764-5, I made experiments at Glasgow on the subject, in the course of my endeavours to improve the steam-engine, and as I did not then think of any *simple* method of trying the elasticities of steam at temperatures less than that of boiling water, and had at hand a digester by which the elasticities at greater heats could be tried, I considered that, by establishing the ratios in which they proceeded, the elasticities at lower heats might be found nearly enough for my purpose. I therefore fitted a thermometer to the digester with its bulb in the inside, placed a small cistern with mercury also within the digester, fixed a small barometer tube with its end in the mercury, and left the upper end open. I then made the digester boil for some time, the steam issuing at the safety-valve, until the air contained in the digester was supposed to be expelled. The safety-valve being shut, the steam acted upon the surface of the mercury in the cistern, and made it rise in the tube. When it reached to 15 inches above the surface of the mercury in the cistern, the heat was 236°; and at 30 inches above that surface, the heat was 252°. Here I was obliged to stop, as I had no tube longer than 34 inches, and there was no white glass made nearer than Newcastle-upon-Tyne. I therefore seal-

* See Chemistry.

ed the upper end of the tube hermetically whilst it was empty, and when it was cool immersed the lower end in the mercury, which now could only rise in the tube by compressing the air it contained. The tube was somewhat conical; but by ascertaining how much it was so, and making allowances accordingly, the following points were found, which, though not exact, were tolerably near for an apperçu. At 29½ inches (with the sealed tube) the heat was 252°, at 75½ inches the heat was 264°, and at 110½ inches 292°. (That is, after making allowances for the pillar of mercury supported, and the pillar which would be necessary to compress the air into the space which it occupied, these were the results.) From these elements I laid down a curve, in which the abscissæ represented the temperatures, and the ordinates the pressures, and thereby found the law by which they were governed sufficiently near for my then purpose. It was not till the years 1773-4, that I found leisure to make further experiments on this subject, of which, though I do not consider the results as accurate, I shall give an account here, as they were in point of date prior to any other that I was then acquainted with.

A tin pan of about five inches in diameter, and four inches deep, had a hole made in its bottom near one side, and in this hole was soldered a socket somewhat conical, which nearly fitted a barometer tube with which the experiments were to be made. This tube was about 36 inches long, and had a ball at one end about 1½ inches diameter, the contents of which were nearly equal to those of the stem of the tube; some paper was lapped round the tube near the ball, and it was forced tight into the conical socket of the pan, so that the ball was within the latter, at such a height that it might be immersed in water. The tube and pan were then inverted, and the ball was filled with clean mercury, and the stem with distilled water fresh boiled. The tube was re-inverted, so that the ball and pan were uppermost; the lower end of the tube being shut by the finger, the water ascended into the ball, and the mercury occupied the tube. The lower end of the latter being then placed in a cistern of mercury, and released from the finger, the mercury and water descended, and the ball was left partly empty: being agitated in this position, and let stand some time, much air was extricated from the water; the tube was inclined as much as it could be, and again inverted, the air let out, and its place supplied with boiling water. It was again placed with the ball uppermost, the end of the tube stopt, the pan filled with hot water which was made to boil by means of a lamp, the lower end of the tube being placed in the cistern, and released from the finger, the mercury descended into the cistern, but, upon the water in the pan being suffered to cool, partly rose again into the tube. Much air was thus liberated, and more was got rid of by agitation, in the manner of the water-hammer, and by leaving it standing for some time erect, until at last I got it so free from air, that when I raised it upright, it supported a column of mercury 34 inches high; and no vacuum was formed until it was violently shaken, when it fell down suddenly and settled at 28.75 inches, but upon being inclined, a speck of air always remained, though, when it was expanded by a pillar of mercury 27 inches high, this speck was not larger than a pin's head.

In this state, when the tube was perpendicular, I found the mercury to stand at 28.75 inches, the column of water above it was about 6½ inches, half an inch of mercury. The whole then being 29.25 inches when the stationary barometer stood at 29.4, the difference, or pillar supported by the elasticity of the steam = 0.15 inch. The water in the pan was then heated exceeding slowly by a lamp, and stirred continually by a feather, to make the heat as equal as possible. The results are shown in the following table.

To determine the heats at which water boils when pressed by columns of mercury above 30 inches, a tube of 55 inches long was employed; one end was put through a hole in the cover of a digester, and made tight by being lapped round with paper, and within the digester the end of the tube was immersed in a cistern of mercury. A thermometer was fixed in another opening, so that the bulb was in the inside of the digester, and the stem and scale without: and the bulb was kept half an inch from the cover of the digester by a wooden collar. The cover being fixed on tight, and the digester half filled with water, it was heated by means of a large lamp.

The air in the upper part of the digester expanding by heat, the column of mercury in the tube was considerably raised by that expansion before the water boiled. The air was let out, and the water heated to boiling; still, however, some air remained, for the mercury stood at 213½°. That deduction being made, the following table shows the heats and corresponding elasticities.

In making these experiments, the digester was heated very slowly, and the heat was kept stationary as much as was possible at each observation, so that the whole series occupied some hours. The degrees of elasticity were observed by my friend Dr. Irvine, whilst I observed those of the thermometer in all these experiments.

With the whole of the observations, I was, after all, by no means satisfied, as I perceived there were irregularities in the results which my more urgent avocations did not permit me to explore the cause of, and to correct.

Table of the Elasticities of Steam for Heats below and above the Boiling Point, according to Mr. Watt.

Heats.	Elasticities	Heats.	Elasticities	Heats	Elasticities	Heats	Elasticities
Deg.	Inches.	Deg.	Inches	Deg.	Inches	Deg.	Inches
55	0.15	175	12.83	223.5	36	248.5	56
74	0.65	177.5	13.81	225	37	250.5	58
81	0.80	180	14.73	226.5	38	252.5	60
95	1.30	182.5	15.66	228	39	255	62
104	1.75	185	16.58	229.5	40	257	64
118	2.68	187	17.51	231	41	259	66
128	3.60	189	18.45	232.5	42	261	68
135	4.53	191	19.38	234	43	262.5	70
142	5.46	193.5	20.34	235	44	264.5	72
148	6.40	196.5	21.26	236.5	45	265.5	74
153	7.325	213	30	237.5	46	268	76
157	8.25	215	31	238.5	47	269.5	78

172	11.95	222	35	247	54		

[illegible] lished, in the Memoirs for [illegible] ments on the elasticity of steam, from the tempera-ture of 32° to that of 212°. The following are a few of the results, which are here compared with those of Mr. Watt and Mr. Robison:

Temperature.	Achard. Elasticities. Inches.	Watt. Elasticities. Inches	Robison. Elasticities. Inches.
168°	11.05	11.24	10.50
189	18.5	18.45	17.47
209	28.1	27.88	26.05

The following results were obtained by Dr. Robison by the different operations which he has described in the article Steam in his works.

Temperatures.	Elasticities.	Temperatures	Elasticities.
32°	0.0	160	8.65
40	0.1	170	11·05
50	0.2	180	14.05
60	0·35	190	17.85
70	0.55	200	22.62
80	0.82	210	28.65
90	1.18	220	35.8
100	1.6	230	41.5
110	2.25	240	54.9
120	3·0	250	66.8
130	3.95	260	80.3
140	5.15	270	94.1
150	6.72	280	105.9*

The next experiments on the elasticity of steam were made by Mr. Bettancourt, an ingenious Spaniard, who communicated them in 1790 to the Academy of Sciences, who published them in the *Memoires des Sçavans Etrangeres.*

The following are some of the results reduced to English inches, and to Fahrenheit's thermometer:

Temp. Fahr.	Elasticities. Inches.	Temp. Fahr.	Elasticities. Inches.	Temp. Fahr.	Elasticities. Inches.	Temp. Fahr.	Elasticities. Inches.
0		104	1.86	167	10.[illegible]7	230	41.38
41	0.0795	113	2.43	176	12.8[illegible]	239	53.77
50	0.1855	122	3.17	185	15.88	248	61.45
59	0.3133	131	4.05	194	19.66	257	76.32

86	1.02	158	8.21	221	36.55	[illegible]	104.91
95	1.30						

Mr. Bettancourt made similar experiments on the elasticity of the vapour of spirit of wine, and he found it at all temperatures equal to $2\frac{1}{4}$ times that of steam.

The next set of experiments on steam were made by Mr. Dalton about 1800, with a degree of accuracy and care, which gives them a high value. The results from 32° to 212° were obtained by direct experiment, but those from 212° to 325° were obtained by calculation.

The following is his own account of the method by they were made:—

I take a barometer tube perfectly dry, and fill it with mercury just boiled, marking the place where it is stationary; then having graduated the tube into inches and tenths by means of a file, I pour a little water, (or any other liquid the subject of experiment) into it, so as to moisten the whole inside; after this, I again pour in mercury, and carefully inverting the tube, exclude all air. The barometer, by standing some time, exhibits a portion of water, &c. of one-eighth or one-tenth of an inch upon the top of the mercurial column, because, being higher, it ascends by the side of the tube, which may now be inclined, and the mercury will rise to the top, manifesting a perfect vacuum from air. I next take a cylindrical glass tube, open at both ends, of two inches diameter, and fourteen inches in length, to each end of which a cork is adapted, perforated in the middle, so as to admit the barometer tube to be pushed through, and to be held fast by them; the upper cork is fixed two or three inches below the top of the tube, and is half cut away, so as to admit water, and to pass by, its service being merely to keep the tube steady. Things being thus circumstanced, water of any temperature may be poured into the wide tube, and thus made to surround the upper part, or vacuum, of the barometer; and the effect of temperature in the production of vapour within, can be observed from the depression of the mercurial columns. In this way, I have had water as high as 155° surrounding the vacuum; but as the highest temperatures might endanger the glass apparatus, instead of it I used the following:—

Having procured a tin tube, of four inches in diameter, and ten feet long, with a circular plate of the same, soldered to one end, having a round tube in the centre, like the tube of a reflecting telescope, I got another smaller tube of the same length soldered into the larger, so as to be in the axis or centre of it; the small tube was open at both ends, and on this construction, water could be poured into the large vessel to fill it, whilst the central tube was exposed to its temperature. Into this central tube, I could insert the upper half of a syphon barometer, and fix it by a cork, the top of the narrow tube also being corked; thus, the effect of any temperature under 212° could be ascertained, the depression of the mercurial columns being known by the ascent in the exterior leg of the syphon.

The force of vapour from water between 80° and 212°, may also be determined by means of an air-pump; and results exactly agree with those determined above. Take a florence flask, half filled with hot water, into which insert the bulb of a thermometer, then cover the whole with a receiver on one of the pump-plates, and place a barometer gage on the other; the air being slowly exhausted, mark both the thermometer and barometer at the moment ebullition commences, and the height of the barometer gage will denote the force of vapour from water of the observed temperature. This method may also be used for other liquids. It may be proper to observe, the various thermometers used in these experiments were duly adjusted to a good standard one.

* "Experiments on this subject have been published by M. De Bettancourt, (See Prony Arch. Hydraulique) by Mr. Schmidt, and by Mr. Dalton, (see Manchester Memoirs)

After repeated experiments by all these methods, and a careful comparison of the results, I was enabled to digest the following table of the force of steam from water, in all the temperatures from 32° to 212°.

Mr. Dalton's Table of the force of Vapour from Water at every Temperature, from that of the congelation of Mercury, or 40 degrees below Zero, or 325 degrees.

Dissatisfied with his own experiments, in the results of which he observed irregularities which he could not explain, Mr. Watt, in the year 1796, requested Mr. Southern to try them over again, and, in fulfilling his request, he was assisted by Mr. William Creighton. The results of these experiments, which were first published in Dr. Brewster's edition of Professor Robison's works, vol. ii. p. 16. are as follows:—

Mr. Southern's Experiments on the Elasticity of Steam.

As Dr. Ure's experiments have been regarded as furnishing us with the most accurate and uniform series of results, we shall lay before our readers an account of the apparatus and methods by which they were made.

Fig. 1. Plate DIV. "represents the apparatus used for temperatures below and a little above the boiling point, and Fig. 2. and 3. for higher temperatures, Fig. 3. being the most convenient. "One simple principle," says Dr. Ure, "pervades the whole train of experiments, which is, that the progressive increase of elastic force developed by heat from the liquid incumbent on the mercury at *l l′ l″* (Fig. 1, 2, 3.) is measured by the length of columns which must be *added* over L, the primitive level below, in order to restore the quicksilver to its primitive level above at *l*. These two stations or points of departure are nicely defined by a ring of platina wire twisted firmly round the tube.

At the commencement of the experiment after the liquid now freed from the air has been let up, the quicksilver is made a tangent to the edge of the upper ring, by cautiously pouring mercury in a slender stream into the open leg of the syphon D. The level ring below is then carefully adjusted.

From the mode of conducting these experiments, there remained always a quantity of liquid in contact with the vapour, a circumstance essential to accuracy in this research.

Suppose the temperature of the water or the oil in A to be 32°, F. as denoted by a delicate thermometer, or by the liquefaction of ice, communicate heat to the cylinder A by means of two argand flames playing gently on its shoulder at each side. When the thermometer indicates 42°, modify the flames, or remove them, so as to maintain an uniform temperature for a few minutes. A film, or line of light, will now be perceived between the mercury and the ring at *l*, as is seen under the vernier of a mountain barometer, when it is raised a few feet off the ground. Were the tube at *l* and L, of equal area, or were the relations of the areas experimentally determined, then the rise of the quicksilver above L would be one half, or a known submultiple of the total depression, equivalent to the additional elasticity of the vapour at 42°, above that at 32°. Since the depressions, however, for 30 or 40 degrees in this part of the scale are exceedingly small, one half of the quantity can scarcely be ascertained with suitable precision, even after taking the above precautions; and besides, the other sources of error, or, at least, embarrassment, from the inequalities of the tube, and from the lengthening space occupied by the vapour as the temperature ascends, renders this method of reduction very ineligible."

By the other plan, we avoid all these evils. For whatever additional elasticity we communicate to the vapour above *l*, it will be faithfully represented and measured by the mercurial column, which we must add over L, in order to overcome it, and restore the quicksilver under *l* to its zero, or initial level, when the platina ring becomes once more a tangent to the mercury.

At E, a piece of cork is fixed between the parallel legs of the syphon to sustain it, and to serve as a point, by which the whole is steadily suspended.

For temperatures above the boiling point, the part of the syphon under E is evidently superfluous, merely containing in its two legs a useless weight of equipoise mercury. Accordingly, for high heats, the apparatus, Figs. 2 or 3 is employed, and the same method of procedure is adopted. The apertures at O, Fig. 3, admits the ball of the thermometer, which rests as usual on *l*." The recurved part of the tube is filled with mercury, and then a little liquid is passed through it to the sealed end. Heat is now applied by an argand flame to the bottom of C, which is filled with oil or water, and the temperature is kept steadily at 212° for some minutes. Then a few drops of quicksilver may require to be added to D″ till L″ and *l″* be in the same horizontal plane. The further conduct of the experiment differs in no respect from what has been already described. The liquid at C is progressively added over L″ to restore the initial level or volume at *l″*, by equipoising the progressive elasticity. The column above L″ being measured, represents the succession of elastic forces. When this column is wished to extend very high, the vertical tube requires to be placed for support in the groove of a long wooden prism.

The height of the column in some of the experiments being scarcely twelve feet, it became necessary to employ a ladder to reach its top. It was found to be convenient in this case, after observing that the column of vapour had attained its primitive magnitude, to note down the temperature with the altitude of the column, then immediately to pour in a measured quantity of mercury, nearly equal to three vertical inches, and to wait till the slow progress of the heating again brought the vapour in equilibrio with this new pressure, which at first had pushed the mercury within the platina ring at *l″*. When the lower surface of the mercury was again a tangent to this ring, the temperature and altitude were both instantly observed. This mode of conducting the process will account for the experimental temperature being very often odd and fractional numbers. They are, therefore, presented to the public as they were recorded on the instant.

The thermometers were constructed by Creighton with his well known nicety; and the divisions were read off with a lens, so that one-sixteenth of a degree could be distinguished. After bestowing the utmost pains in repeating the experiments during a period of nearly two months, it was found that the only way of removing the little discrepancies which crept in between contiguous measures, was to adopt the astronomical plan of multiplying observations, and deducing truth from the mean. It is essential to heat with extreme slowness and circumspection the vessels A, B, C. One repetition of the experiment occupies, on an average, seven hours."

The next experiments on the elasticity of steam, were those of Mr. Philip Taylor, at temperatures from 212° to 320°. The results which he obtained, are given in the following table.

Mr. Philip Taylor's Experiments on the Elasticity of Steam, from 212°—320° Fahrenheit.

Temp.	Elasticity in inches.	Temp.	Elasticity in inches.	Temp.	Elasticity in inches.	Temp.	Elasticity in inches.

Most of the philosophers who have investigated the elastic force of steam, have endeavoured to construct empirical formulæ, for representing the relation between the temperatures and the elastic forces. It would be a waste of time to reprint and to explain these formulæ, as they are of little service when we possess the experimental results.

Our distinguished countryman, however, Mr. Ivory, has recently investigated a numerical formula, with the view of finding some property or law which may give us some general information respecting the elasticities beyond the range of our experiments. For this purpose he makes Dr. Ure's experiments the ground work of the following table:—

Mr. Ivory's Comparative Table of Dr. Ure's Experiments on Steam.

Indices x.	Temperatures τ	Elastic forces in inches of mercury e.	Log. of elasticities in parts of an atmosphere of 30 in. Log. $\frac{e}{30}$	Temperature below and above boiling point t.	Log. $\frac{e}{30}$ / t	Diff.	Computed quantities. Log. $\frac{e}{30}$ / t	Elastic forces in inches.
0	50°	0.360	—1.29082	—162	.011857		.011857	0.360
1	70	0.726	—1.61618	—142	.011381	476	.01110[illegible]	0.721
2	90	1.360	—1.34359	—122	.011013	368	.010968	1.378
3	110	2.456	—1.08689	—102	.010656	357	.0105[illegible]	2.634
4	130	4.366	—0.83704	— 82	.010208	448	.010158	4.468

1	2	3	4	5	6	7		9

In the above table, col. 2, marked τ denotes the temperatures beginning at 50°, and increasing by 20° as far as Dr. Ure's table carries us. In col. 1. are the indices x, or the number of intervals of 20°. Hence we have for any temperature the corresponding index.

$$x = \frac{\tau - 50}{20}$$

The third column contains the elasticities e as found by Dr. Ure, and then follow in column fourth, the logarithms of the same elasticities estimated in parts of an atmosphere of 30 inches. Column fifth contains the temperatures, reckoned from the boiling point, those below it being negative, and those above it positive. Column sixth is the quotient of column fourth divided by column fifth. These quotients are irregular, near 212°, because as $\frac{e}{30}$ approaches to unity, its log. varying rapidly with any variation of e, the errors of observation have a great influence in this part of the table. It is remarkable that the numbers in this column continually decrease, and it would be interesting to determine if they would decrease to a fixed limit, or if they would decrease to a minimum and then increase again. Column seventh contains the differences in these quotients which are extremely irregular, and which, taken directly, seem to furnish no clue to guide us in our present research. But as they decrease slowly, we may infer that the quotients may be expressed with tolerable accuracy by means of the first and second orders of differences. If we represent the first and second differences by Δ and Δ^2, we have the following general expression of the quotient corresponding to the index x.

$$\frac{\text{Log. } \frac{e}{30}}{t} = .011857 - x \cdot \Delta + \frac{x^2 - x}{2} \Delta^2 \quad \text{(A)}$$

Two values in the table answering to given indices, are sufficient for finding Δ and Δ^2; but on account of the irregularities of observation, it will be better to proceed as follows: Form the expressions of the seven quotients in the table corresponding to the indices 1, 2, 3—7, and take a mean of the whole; thus

$$.010198 = .011857 - 4\,\Delta + 8\,\Delta^2.$$

In like manner, form the expressions of the four last quotients, and take a mean; thus,

$$.007842 = .011857 - \frac{23}{2}\,\Delta + 61\,\Delta^2.$$

By means of these two equations we get $\Delta = .0004545$ and $\Delta^2 = 00001986$, and by these values of Δ and Δ^2 the values of $\frac{\text{Log.}\ \frac{e}{30}}{t}$ and of e are computed by the formula A, and inserted in columns 8 and 9. Thus to find e for temperature 130° and index 4 we have $t = -82°$ and $\frac{\text{Log.}\ \frac{e}{30}}{-82°} = .010158$ whence

$$\text{Log.}\ \frac{e}{30} = -0.8329 = -1 + .1671, \text{ then}$$

$$\begin{array}{lr} & -1.1671 \\ \text{Log. } 30 & 1.4771 \\ \hline \text{Log. } e & 0.6442, \end{array}$$

$e = 4.408$. In this way all the elasticities in col. 9. have been calculated, and their agreement with the experimental quantities is very striking, so that the formula A may be considered as representing the elasticities as exactly as could be wished.

In reducing the formula to a proper form for use, Mr. Ivory proceeds thus, substituting the values of Δ and Δ^2, and arranging the terms according to the powers of x. Thus

$$\frac{\text{Log.}\ \frac{e}{30}}{t} = .011857 - .00046143\,.\,x + .00000993\,.\,x^2$$

$$\text{But } x = \frac{\tau - 50}{20} = \frac{162 + t}{20}$$

wherefore by substituting,

Logarithms of co-efficients.

$$\begin{array}{lll} \text{Log.}\ \frac{e}{30} = .0087466\,t & - & 3.9418393 \\ \quad - .000015178\,t^2 & - & 5.1812202\ (B) \\ \quad + .000000024825\,t^3 & - & 8.3871228. \end{array}$$

At 32°, $t = -180°$ and e, comes out 0.185, very near 0.2, Dr. Ure's result. Hence the formula (B) is nearly exact for the range of Dr. Ure's experiments.

Mr. Ivory then proceeds to apply this formula to two experiments, at temperatures of 343° and 419°, made by Mr. Southern and Mr. Clement. He finds that at 343°, it gives the elasticity 261 inches, which is 24 inches above Mr. Southern's result: but at 419° the formula gives only 23.8 atmospheres in place of 35 atmospheres, as determined by Mr. Clement. "The formula therefore," says Mr. Ivory, "although it is very accurate for a long range of temperatures, finally digresses altogether from the truth." Mr. Ivory is led to the important result that the quotient $\frac{\text{Log.}\ \frac{e}{30}}{t}$ decreases to a minimum, and then increases again, not only in the formula, but in nature. For example, in Clement's experiment, where $t = 207$, we have $\frac{\text{Log.}\ 35}{207} = .007454$, but in the table we find .007454 in the column of quotients opposite 310°; consequently, while the temperature increases from 310° to 419°, the quotient must have decreased to a minimum, and then increased again to its first magnitude. Hence Mr. Ivory concludes that the minimum takes place at 364½°, or about 152° or 153° beyond the boiling point.

Mr. Ivory concludes by stating, that the quotient is represented by the square of the ordinate to the conjugate axis of a hyperbola, the square of the semi-transverse axis being the minimum, for the expression B becomes $\frac{\text{Log.}\ \frac{e}{30}}{t} = A + B\,(n - t)^2$ A and B being known numbers, and n the distance of the minimum from the boiling point.

The expansive power of steam had been hitherto examined and used only at moderate temperatures, till Mr. Oliver Evans of Philadelphia, and Mr. Jacob Perkins, conceived the idea that great advantage would be gained by using steam of a high expansive force. "When I reflected," says Mr. Perkins, "on the almost infinite power that is sometimes displayed in the eruptions of Mount Vesuvius, throwing up incalculable masses of matter into the very clouds, I was induced to consider how this immense power could be generated. How is it that this power is so wonderfully great? Is it not high elastic steam? The thought struck me that it must be owing to the water being confined by pressure, until it got sufficiently charged with heat to enable it to rend asunder whatever confined it, thereby driving every thing before it. If one wanted farther proof of the tremendous power of steam, we have only to inquire of many practical iron founders what it is which has sometimes caused the liquid iron to leave its mould, and pass off through the roof of the foundry, in a metallic shower. The answer would be, that a small quantity of water had accidentally found its way into the bottom of the mould; and it might also be added, that a thousand times that quantity thrown on its heated surface would be perfectly harmless."

These considerations led Mr. Perkins to make a number of experiments on the elastic force of steam generated at very high temperatures, with the view of improving the high pressure engine. He has applied degrees of temperature so great, that the water in the boiler or gasometer was brought to a red heat. He has not, we believe, completed any regular series of experiments on the elastic force of steam generated with such enormous heat; but he considers the observations which he has made as leading to the following result:—*That while the temperature rises in an arithmetical ratio, the expansive force will be that of an increasing ratio, and the increments of fuel will be a decreasing ratio.*

During these experiments, Mr. Perkins had occasion to observe the very curious phenomenon that steam generated at such high temperatures produced no scalding effect. "I have frequently observed," says he, "that when the stop-cock of a high pressure boiler was opened, whether at the water or steam cocks, the temperature was lowered in proportion to the height of the steam. In a recent experiment on high steam it occurred to me that the great force and rapidity of motion of the steam caused the atmospheric air to be driven before it, evidently tending to produce a partial vacuum, to which the surrounding atmosphere would rush in and diminish its temperature. To test this theory, the following contrivance was resorted to: I took a vessel containing heated water of a temperature of 420 degrees of Fahrenheit; a tube eight inches in diameter. and four feet in length, and open at both ends, was suspended immediately over the stop-cocks, and in such a manner as to be raised or lowered at pleasure. This tube was raised eight inches above the stop-cock; the stop-cock, the area of which was one-fourth of an inch, was then opened, and the steam rushed out with great velocity into and through the tube. It was observed, that the steam condensed rapidly on the inside as well as the outside of it. The tube was lowered directly over the stop-cock, and when it came in contact with the vessel, it allowed very little air to find its way between it and the tube. The condensed steam in the tube immediately evaporated, and the tube soon became too hot for the touch of the hand; and when the thermometer was inserted eight or ten inches into the upper end of the tube, it indicated 230 degrees of temperature. The tube was again raised to about the same height, and immediately the condensation commenced as before.

A lighted lamp was now introduced, and when it was within 24 inches of the tube, the flame of it visibly inclined to where the steam entered the tube. The lamp was then moved gradually towards the lower end of the tube, and at six inches from it the flame disappeared, being carried away by the strong current of the air: The tube was now wholly removed, and it was evident from the inclination of the flame of the lamp, as it was moved eight or ten inches from the volume of the steam, that a strong atmospheric air was continually passing into and going off with it.

The thermometer, when placed twelve inches from the stop-cock, and in the centre of the volume, showed the temperature to be 120 degrees; but when at four or five inches from the centre, although within the circumference of the volume, it was down to eighty degrees, showing, as might have been expected, that where the air first joined the volume, it was less heated. Twenty-four inches above the cock the thermometer was at ninety degrees at the centre: thirty-six inches from it, it was at eighty degrees at the centre.

May we not conclude from this experiment that the cooling down of the steam is occasioned by the great quantity of air which is combined with it; aided in a slight degree by the expansion which takes place immediately after leaving the stop-cock.

I have frequently, since the experiment was made, washed my hands in the water, which, when in the generator, was at 500° of heat, and which was rushing from the stop-cock with very little expansion, but with great velocity, showing clearly, that it is the rapid rush through the atmosphere, and not the expansion only, which cools it down."

STEAM ENGINE.

Steam Engine is the name given to a machine in which the moving power is obtained from the elastic force of steam, and from its capability of being condensed into water, and thus creating a vacuum in the space which it occupied.

Like every other invention which has become important to society, the steam engine has been ascribed to a variety of authors, and he who enjoys the undoubted title to that distinguished honour, has been robbed of his just rights by the obtrusive claims of a number of contrivances, as devoid of genius as they are destitute of utility.

The power of national prejudice has been singularly exhibited, and the spirit of scientific criticism as singularly degraded, when the invention of the steam engine has been ascribed to Hero and Branca, who whirled round a wheel by the steam of a kettle, or to Solomon de Caus, who squirted water out of a vessel by the steam which it generated. Upon such principles, we may refer the invention of the telescope to him who first looked through a glass ball filled with water, and the discovery of the air balloon to the little urchin who first committed his soap bubble to the atmosphere.

That the Marquis of Worcester was the inventor of the steam engine, or of a machine in which the elastic force of steam was proposed as the first mover in raising water, is a fact beyond dispute. In his *Century of Inventions*, a work published in 1663, he has described this engine in No. 68, and he has again referred to it in Nos. 98, 99, and 100. He has also left behind him what he calls a definition of his engine, the only copy of which is preserved in the British Museum. These different articles we shall now lay before our readers.

"No. 68. An admirable and most forcible way to drive up water by fire, not by drawing or sucking it upwards, for that must be, as the philosopher calleth it, *infra sphaeram activitatis*, which is but at such a distance. But this way hath no bounder, if the vessel be strong enough; for, I have taken a piece of a whole cannon, whereof the end was burst, and filled it three quarters full, stopping and screwing up the broken end, as also the touch hole: and making a constant fire under it, within twenty-four hours it burst, and made a great crack: so that having found a way to make my vessels, so that they are strengthened by the force within them, and the one to fill after the other, have seen the water run like a constant fountain's stream, forty feet high; one vessel of water rarefied by fire, drinketh up forty of cold water: and a man that tends the work is but to turn two cocks that one vessel of water being consumed, another begins to force and refill with cold water, and so successively, the fire being tended and kept constant, which the self same person may likewise abundantly perform in the interim between the necessity of turning the said cocks.

No. 98. An engine so contrived that working the *primum mobile* forward or backward, upward or downward, circularly or cornerwise, to and fro, straight upright or downright, yet the pretended operation continueth and advanceth; none of the motions above mentioned, hindering, much less stopping the other; but unanimously, and with harmony agreeing, they all augment and contribute strength unto the intended work and operation; and therefore I call this a *semi-omnipotent engine*, and do intend that a model thereof be buried with me.

No. 99. How to make one pound weight to raise an hundred as high as one pound falleth, and yet the hundred pounds descending doth what nothing less than one hundred pounds can effect.

No. 100. Upon so potent a help as these two last mentioned inventions, a water work is by many years experience and labour, so advantageously by me contrived, that a child's force bringeth up one hundred feet high an incredible quantity of water even two feet diameter; and I may boldly call it *the most stupendous work in the whole world.*

Not only with little charge to drain all sorts of mines, and furnish cities with water though never so high seated, as well to keep them sweet running through several streets, and so performing the work of scavengers, as well as furnishing the inhabitants with sufficient water for their private occasions, but likewise supplying the rivers with sufficient to maintain and make navigable from town to town, and for the bettering of lands all the way it runs, with many more advantageous, and yet greater effects of profit, admiration, and consequence; so that deservedly I deem this invention to crown my labours, to reward my expenses, and make my thoughts acquiesce in way of farther inventions. This making up the whole century, and preventing any farther trouble to the reader for the present, meaning to leave to posterity a book, wherein under each of these heads the means to put in execution and visible trial all and every of these inventions with the shape and form of all things belonging to them, shall be printed by brass plates. Besides many omitted, and some of three sorts willingly not set down as not fit to be divulged, lest ill use may be made thereof, but to show that such things are also within my knowledge, I will here in myne owne cypher sett doun one of each, not to be concealed when duty and affection obligeth me."

The following is the Marquis's definition, which is printed on a single sheet without date, and which Mr. Partington, supposes, had been written to procure subscriptions in aid of a water company then about to be established.

"A stupendous, or a water commanding engine, boundless for height or quantity, requiring no external, not even additional help or force to be set or continued in motion but what intrinsically is afforded from its own operation, nor yet the twentieth part thereof. And the engine consisteth of the following particulars:

A perfect counterpoise for what quantity soever of water.

A perfect countervail for what height soever it is to be brought unto.

A *primum mobile*, commanding both height and quantity, regulator-wise.

A vicegerent or countervail, supplying the place and performing the full force of man, wind, beast, or mill.

A helm or stern, with bit and reins, wherewith any child may guide, order, and control the whole operation.

A particular magazine for water, according to the intended quantity or height of water.

An aqueduct capable of any intended quantity or height of water.

A place for the original fountain or river to run into, and naturally of its own accord incorporate itself with the rising water, and at the very bottom of the aqueduct, though never so big and high.

By divine providence and heavenly inspiration, this is my stupendous water commanding engine, boundless for height and quantity.

Whosoever is master of height is master of force; whosoever is master of water is master of both; and consequently to him all forcible actions and atchievements are easie."

That the engine thus described was actually constructed and put to the test of experiment in some form or other however rude, we think cannot well be doubted. There is nothing in the character of the noble Marquis to justify the supposition that he could deliberately record a falsehood; and still less that he could leave behind him the prayer which he offered up to heaven on the completion of his experiment. This curious document is entitled, "*The Lord Marquesse of Worcester's ejaculatory and extemporary thanksgiving prayer, when first with his corporal eyes he did see finished a perfect trial of his water commanding engine, delightful and useful to whomsoever hath in recommendation either knowledge, profit, or pleasure.*" In this prayer he thanks God, next to his creation and redemption, for "vouchsafing him an insight in soe great a secret of nature beneficial to all mankind as this my water commanding engine."

Those who have opposed the claims of the Marquis of Worcester, have alleged that it is impossible to construct a steam-engine on the principles which he has laid down; but this is not entirely true, and we have great pleasure in giving the following sketch of what was probably the first steam-engine, communicated to us by our able and ingenious correspondent, Mr. Scott of Ormiston.

In Plate DIV. Fig. 4. A represents a boiler placed in a common air furnace: *a b c d*, and *e f g h*, two water vessels; *i k l*, the steam pipes, and *k* the steam cock; *x x x x* the force pipe; RS a cistern, which may be supposed to be placed at the height of forty feet above the engine, to receive the water from the force pipe; and *v v* valves placed within the force pipe to prevent the return of the water; *m n o* the cold water pipes, and *n* the cold water cock; the dotted lines *b z e* represent the cold water fountain, which is here supposed to be immediately behind the engine, and the water in it standing nearly upon a level with the stop of the cold water vessels. Fig. A is a ground plan of the fountain, where *m n o* represent the cold water pipes, *n* the water cock, and F the reservoir. Fig. 6. represents a section of the two cocks, which are in every respect similar; the black circle *a b e* represents the key of the cock, and the black shaded part the passage through the key; the dotted circle *r s t u* the shell or body of the cock, the two dotted lines *t z* the pipe that leads from the boiler, the two dotted lines *s z* the pipe that leads to the right hand water vessel, the two dotted lines *z u* the pipe that leads to the left hand water vessel, and the curved dotted line *x z y* the top of the boiler.

From an inspection of Fig. B, it will appear that by a quarter turn of the key of the cock *k*, (Fig. 4.) the steam may either be directed into the right or left hand water vessel, and in like manner, by a quarter turn of the key of the cock *n*, cold water may be permitted to pass into either of the vessels.

Suppose the fire burning, and the boiler sending forth steam, and the key of cock *k* turned so as to permit the steam to enter into the vessel *a b c d*, then will the steam drive out all the air of that vessel up the force pipe *x x x x*, and occupy its place; steam will then be seen to issue from the nosle *w* of the force pipe. When this is observed, the key of the steam cock *k* must be turned, to permit the steam to pass into the vessel *e f g h*, and at the same time the key of the cold water cock *n* must also be turned, to permit the water from the fountain to be forced into the vessel *a b c d*, (by the pressure of the atmosphere) as the steam therein condenses with the cold water; and when the vessel *a b c d* is filled with water, and the vessel *e f g h* with steam, the key of the steam cock *k* is to be turned back into its first position, which will again permit the steam to pass into the vessel *a b c d*, to act upon the surface of the water in that vessel, so as to drive it up the force pipe *x x x*, and, at the same time, the key of the cold water cock *n* must also be turned, to permit the cold water to condense the steam and fill the vessel *e f g h*, and which will also be forced into this vessel (by the pressure of the atmosphere) to occupy the vacuum effected by the condensed steam. The cock *n* is next to be turned so as to permit the vessel *a b c d* "to force and refill with cold water," and, at the same time, the steam cock *k* is to be turned, so as to permit the steam to act upon the surface of the water in the vessel *e f g h*, and so on alternately, producing a constant stream from the top of the force pipe. The boiler may be supplied with water from the cistern RS, by means of a small pipe and stop-cock.

To produce "a constant stream forty feet high, one vessel of water rarefied by fire, driveth up forty of cold water, (or in other words, forty times the quantity in the boiler.) A man that tends the work is but to turn two cocks, that one vessel of water being consumed, another begins to force and refill with cold water, (by the pressure of the atmosphere) and so successively, the fire being tended and kept constant, which the self same person may likewise abundantly perform in the interim between the necessity of turning the said cocks."

Although the Marquis of Worcester has only proposed to force water by his engine to a great height, yet it appears that he knew that water could have been brought up from a limited depth by suction, (by the pressure of the atmosphere into a vacuum;) for the 68th article commences with these words: "An admirable and most forcible way to drive up water by fire, not by drawing nor sucking it upwards, for that must be, as the philosopher calleth it, *intra sphæram activitatis*, (within its sphere of activity) which is but at such a distance."

It is therefore very obvious, that the Marquis had a knowledge to what height water could have been raised from the effects of a vacuum, and which he had put a small value upon in comparison of what he had in view; for he adds, "but this way hath no bounder if the vessels be strong enough." The Marquis a little further on says, "so that having a way to make my vessels, so that they are strengthened by the force within them."

This can only apply to strengthening his boiler and vessels by rivetting radiating arms inside of them, and making them in other respects strong.

Sir Samuel Morland, celebrated as the inventor of the speaking trumpet, appears to have directed his attention, in 1682, to the force of steam as a means of raising water. In 1681, he was sent by Charles II. to Louis XIV., to direct the execution of water works in France, and while he was in that country in 1683, he wrote a small treatise in French, entitled *Elevation des Eaux par toutes sortes des Machines reduite a la Mesure au Poids, et a la Balance.* This work was presented to the French king, and is preserved in the Harleian collection at the British Museum. The chapter on Steam Engines, which occupies only the last four pages, is as follows: "The *Principles of the New Force of Fire invented by the Chevalier Morland in the year* 1682, *and presented to his Christian Majesty* 1683. Water being evaporated by the force of fire, these vapours immediately occupy a much greater space (about 2000 times) than the water occupied before, and its power is so great that if closely imprisoned it will burst a piece of cannon. But being governed according to the rules of statics, and reduced by science to measure, weight, and balance, it then bears itself quietly under the harness (like good horses) and becomes of great use to mankind, particularly to raise water according to the following table, which shows the number of pounds which can be raised 1800 times per hour to the height of six inches, in cylinders about half filled with water, as well as the different diameters and depths of the cylinders.

Cylinders.

Diameter in feet.	Depth in feet.	Pounds weight to be raised
1	2	15
2	4	120
3	6	405
4	8	960
5	10	1875
6	12	3240

Number of cylinders, having a diameter of six feet, and a length of twelve feet.	Required to raise the following weight of water.
1 - - -	3,240 pounds
2 - - -	6,480
3 - - -	9,720
4 - - -	12,960
5 - - -	16,200
6 - - -	19,410
7 - - -	22,680
8 - - -	25,920
9 - - -	29,160
10 - - -	32,400
20 . - -	64,800

Among the eminent men who speculated respecting the use of steam as a moving power, Dr. Denys Papin deserves an honourable place. Driven from his own country by the revocation of the edict of Nantes, he resided in London from 1680 to 1687. He seems to have invented his digester in 1680, and during the experiments which he made with it, he was necessarily led to observe the expansive force of steam, and to ascertain its great power from the strength which his digesters required, and the means which were necessary to keep down their covers. In the *Acta Eruditorum* of Leipsic, for 1690, he has described the following engine, which cannot fail to be considered by every candid inquirer as a real step to the invention of the steam engine. A cylinder AA, Plate DIV. Fig. 7. made of thin metal, is fitted with a piston B, which can slide freely up and down in the cylinder. A small quantity of water being put into the bottom of the cylinder, and the piston B depressed so as to touch the water, the air being driven out through a hole in the piston, which is afterwards closed by a plug M. The water being made to boil by a fire beneath the cylinder, it is changed into vapour, which exerts so strong a pressure against the piston that it surmounts the pressure of the atmosphere, and pushes the piston upwards to the top of the cylinder. The piston is prevented from descending by a latch E falling into a notch in the stem H of the piston. The fire must now be removed from beneath the cylinder, and the vapours in this cylinder soon recondense themselves into water by cold, and leave the cylinder entirely free of air. In this state the machine is ready to exert its force, for, by loosening the latch E, the piston will be pressed down into the cylinder by the weight of the atmosphere which presses upon its upper surface while there is no air beneath to resist its descent, and a rope fastened to the stem of the piston H may be taken over pulleys TT, and applied to raise weights. Papin actually tried this experiment with a cylinder 2½ inches in diameter, by which he raised 60 lbs., and he made it repeat its action once in a minute. Hence he computed that a cylinder about two feet in diameter and four feet high would raise 8000 lbs. every minute four feet high, which is nearly a horse power.

Papin states that this invention is suited to draw water from mines, to throw bombs, and to row vessels against wind and tide. For this last purpose, he proposed to fix on the sides of the vessels revolving rowers or paddle wheels, and by means of three or four of his new invented cylinders, to give a combined motion to the axis on which the paddle wheels are fixed. In order to give this motion to the wheels, the piston rods were to be toothed so as to drive small toothed wheels fitted on the axis of the paddle wheels, whenever the pressure of the atmosphere caused the pistons to descend into their respective cylinders. In order to make the motion of the paddle wheels uninterrupted, several cylinders were to work in succession one acting while the rest were heating. The toothed wheels on the axis of the paddles were to have ratchets and clicks that they might revolve freely in an opposite direction to the axis when the pistons were rising in their cylinders, but when the pistons were pressed down into the cylinders, the clicks would catch in the teeth of their ratchets, and carry the axis round with the toothed wheels.

This scheme was reprinted in 1695 in the *Recueil de diverses pieces touchant quelques nouvelles Machines par D. Papin, Cassel* 1695, in which he describes a new invented furnace and revolving bellows, which he had contrived to boil water by an internal fire-place, surrounded on all sides by the water; and he endeavours to show how it could be applied to heat the cylinders of his proposed engine with such increased rapidity as to perform four strokes in a minute. Papin made one of these machines in 1698, but before he had put it to the test of experiment it was destroyed by an accident.

It is impossible to peruse these details without being convinced that this ingenious author had advanced a considerable way in the construction of the steam engine, and had almost invented some of its most useful applications. We feel much satisfaction in having an opportunity of acknowledging the merits of this ingenious foreigner, as we had been induced, on the authority of Dr. Robison, and by an imperfect examination of the subject, to do injustice to the genius of this able author, when we had occasion to discuss the subject in another work.*

Notwithstanding all these attempts to construct a steam engine, no machine of this kind had yet been executed and applied to actual use. The honour of this great step was reserved for Captain† Thomas Savery, treasurer to the commissioners of sick and wounded. In a pamphlet entitled the Miner's Friend, published in 1696, he described a steam engine in which water is raised not only by the expansive force of steam, but also by its condensation, the water being raised by the pressure of the atmosphere into receivers, from which it is forced to a greater height by the elastic force of the steam. After having erected several of these engines, Savery took out a patent, in 1698, for a new invention "for raising water and occasioning motion to all sorts of mill work." In June 1699, he exhibited a working model to the Royal Society, who printed in their transactions for that year a drawing and description of it; but the most complete account of it appeared in a small pamphlet of eighty-four pages 12mo. which Mr. Savery published in 1707, under the title of "The Miner's Friend, or an Engine to raise Water by Fire described; and the manner of fixing it in Mines, with an account of the several uses it is applicable unto, and an answer to the objections made against it." This book was separately addressed to King William III. to whom the engine had been shown at Hampton Court.

This engine, which is perfect so far as it goes, displays much ingenuity. The following is Savery's own description of it, with some additions as given in Harris's *Lexicon Technicum*, vol. i. Art. Engine.

A A The furnaces which contain the boilers.

B1, B2. The two fire places.

C The funnel or chimney which is common to both furnaces. In these two furnaces are placed two vessels of copper, which I call boilers, the one large as L, the other small as D.

D The small boiler contained in the furnace, which is heated by the fire at B 2.

* In the short notice of the history of the steam engine, given by the Abbé Bossut in his *Hydrodynamique*, he has placed the invention of Savery after a contrivance of M. Dalesme in 1705, whereas, as will be presently seen, the date of Savery's patent is 1698. In consequence of this mistake, the invention of Dr. Papin, published in 1709, obtains the precedency of Captain Savery's engine. See Bossut's *Traité D'Hydrodynamique*, tom. II. p. 476. Paris, 1796.

† Mr. Farey informs us that the Cornish miners give the title of Captain to engineers, and that Savery hence derived it.

E The pipe and cock to admit cold water into the small boiler to fill it.

F The screw that covers and confines the cock E to the top of the small boiler.

G A small guage cock at the top of a pipe going within eight inches of the bottom of the small boiler.

H H A larger pipe which goes the same depth into the small boiler.

I A clack or valve at the top of the pipe H, (opening upwards.)

K K A pipe going from the box above the said clack or valve, into the great boiler and passing about an inch into it.

L L The great boiler contained in the other furnace, which is heated by the fire at B 1.

M, Fig. 9. The screw with the regulator which is moved by the handle Z, and opens or shuts the apertures at which the steam passes out of the great boiler into the steam pipes O, O.

N *n* Two small guage pipes which go down into the great boiler, one of which N has its lower end a little above the proper depth of water, and the other *n* a little below it, so that when N gives steam upon turning the cock, and *n* water, the water is at its proper height.

O1, O2. Steam pipes, one end of each is screwed to the regulator, (See Fig. 9.) and the other ends to the receivers PP, to convey the steam from the great boiler into those receivers.

P1, P2. Copper vessels called receivers, which are to receive the water which is to be raised.

Q Screw joints, by which the branches of the water pipes are connected with the lower parts of the receivers.

R1, 2, 3, and 4, valves or clacks of brass in the water pipes, two above the branches Q, and two below them; they allow the water to pass upwards through the pipes, but prevent its descent; there are screw plugs to take out on occasion, to get at the valves R.

S The forcing pipe which conveys the water upwards to its place of delivery, when it is forced out from the receivers by the impellent steam.

T The sucking pipe which conveys the water up from the bottom of the pit to fill the receivers by suction.

V A square frame of wood or a box with holes round its bottom in the water, to inclose the lower end of the sucking pipe to keep away dirt and obstructions.

X A cistern with a buoy cock coming from the force pipe, so as it shall always be kept filled with cold water.

YY A cock and pipe coming from the bottom of the said cistern, with a spout to let the cold water run down on the outside of either of the receivers P, P.

Z The handle of the regulator to move it by either open or shut, so as to let the steam out of the great boiler into either of the receivers.

The mechanism of the regulator and the guages will be better understood from the section of the boiler shown in Fig. 10. R being the regulator moved by the handle Z in Fig. 8, 9, which can thus be brought to slide alternately over the mouths of either of the pipes O 1, O 2.

The two boilers D, L are fixed in a good double furnace, so constructed that the flame of the fire may circulate round them. Before the fire is lighted, unscrew the guage pipes and cocks G and N, and at the holes fill the great boiler L two-thirds full of water and the small boiler D quite full. When these pipes are again screwed as tight as possible and the water brought to boil by the fire under the large boiler B 1, steam will be raised, and will endeavour by its elastic force to make its escape. This is effected by pushing from you the handle Z of the regulator (R Fig. 10.) as far as it will go, when the steam will rush with great force through the steam pipe O 1 into the receiver P 1, driving out all the air before it, and forcing it up through the clack R1 into the force pipe. When the receiver P 1 is thus thoroughly emptied and has become very hot, pull towards you the handle Z of the regulator, which will remove the slide R, Fig. 10. from the mouth of the pipe O 2, and place it on the mouth of the pipe O 1, so that no more steam can come into the receiver P 1, when it passes freely through the other steam pipe O 2, and fills the other receiver P 2, heating it and discharging its air through the clack R 2 up the force pipe.

Having condensed the steam in the receiver PY by cold water, from the spout Y, a vacuum will be created in it, and as there is nothing at the bottom of the receiver P 1 to counterbalance the pressure of the atmosphere on the surface of the water at the lower spout V of the sucking pipe T, the water will be pressed np and will fill the receiver P 1 by suction, the water lifting up the clack valve R 3, which afterwards falling down prevents the water from returning that way.

The receiver P 2 being emptied of its air, admits the steam again through O 1, and by its elastic force, which exceeds the weight of the column of water in the receiver and pipe S, it will press on the surface of the water and drive it up through the passage R 1 into the force pipe S, discharging it at the top as shown in the figure. In the same manner the receiver P 2 is alternately filled with water by suction, and then emptied by the elastic force of the steam, so as to keep up a constant stream at the top of the force pipe S. When the water has half filled the force pipe S, it also fills the little cistern X, by which the condensing pipe YY is supplied. This pipe can be turned sideways by its handle *n*, so as to throw cold water on the outside of either of the receivers.

The labour of turning the regulator Z, and the handle *h* of the condensing watercock, may be easily performed by a boy, though Mr. Savery recommends the employment of an intelligent workman. The use of the small boiler D is to replenish the large one L with water, which sinks in it about one foot in one and a half or two hours. For this purpose, the small boiler D is supplied with water from the force pipe by a small pipe and cock E, Figs. 8 and 10, which is closed when the boiler D is nearly full. A fire is then lighted in the furnace B *r*, and in consequence of the elasticity of the steam which it produces being stronger than that in the boiler L, it presses upon the water in

D, Fig. 10, forces it up the pipe HH, and through the cock I (which is for this purpose open) into the boiler L, into which it will flow till the surface of the water in D has descended to the lower end of the pipe H, which is within eight inches of the bottom. The size of the boiler D is such, that it supplies L with exactly one foot of water. In order to ascertain when the boiler L requires more water, we have only to turn the guage cocks N, *n*. If steam arises from N and water from *n*, as will happen in the state shown in Fig. 10, then no water is required, but if steam issues from *n* there is then a want of water, and if water should issue from N there is more than is necessary.

After giving the description of his engine, Mr. Savery enumerates the following purposes to which it may be applied, viz: 1. Raising water for turning all sorts of mills. 2. Supplying palaces, noblemen's and gentlemen's houses with water, and affording the means of extinguishing fires therein by the water thus raised. 3. Supplying cities and towns with water. 4. Draining fens and marshes. 5. For ships.* 6. Draining mines with water, and preventing damps in these mines.

The safety valve, which was invented by Papin in 1681, does not seem to have been used by Mr. Savery in any of his engines; and it is also evident from the preceding description of his engine, that he was not the inventor of the injecting pipe, or of the principle of condensing by injection, an honour which Mr. Watt has, by mistake, ascribed to him.†

In examining with some care the various accounts which have been given of Mr. Savery's labours, and the details of his engine, we are strongly disposed to believe, with Mr. Farey, that the whole of it was his own invention, and that he was even unacquainted with the previous contrivance of the Marquis of Worcester. The story told by Dr. Desaguliers, that Savery borrowed his invention from the Marquis of Worcester; and that, in order to conceal the matter, he bought up all the Marquis's books that he could purchase in Paternoster Row, and burned them in the presence of a gentleman who mentioned the thing to Dr. Desaguliers, is so improbable that we cannot give it credit; and even if we did, it could not affect the ingenuity and originality of Savery's engine. Whatever merit we may attach to the contrivance of the Marquis of Worcester, and in whatever manner we may apportion a certain share of merit to the different candidates to whom national partiality may have adjudged the invention of the steam engine, there cannot, we think, be any doubt that Mr Savery stands at the head of the list, and is more entitled to have his name associated with the invention, the construction, and the introduction of the steam engine into actual use, than any other individual that has yet been named.

Dr. Papin, who had still continued to direct his attention to the subject of the steam engine, published in 1707 a small tract, entitled *Nouvelle maniere pour lever l'eau par la force du feu, mis en lumiere*, Cassel. Papin admits in this work that he had seen the engraving of Savery's engine, which M. Leibnitz had sent to him from London; and, therefore, he does not bring forward his engine as having the precedence of Savery's, but merely as a construction which possesses superior advantages. He proposed to the Royal Society, of which he was a member, to bear the expense of constructing an engine upon his plan; but this learned body, who had a communication with Mr. Savery on the subject, do not seem to have attached any value to the contrivance of Papin, which we have represented in Fig. 11.

A copper boiler A communicates by means of a pipe Z with the cylinder I, which is connected by a curve pipe X to an upright OQ, which rises nearly to the top of the cylinder RR. This cylinder, which is air tight, is furnished with a pipe W and stop-cock P, Plate DIV, Fig. 11. Another pipe terminating in a funnel K with a stop-cock at M branches off from the bent pipe X. The pipe Z has a stop-cock at C, and another small pipe at E also furnished with a stop-cock. A *safety valve* F, of which Papin is the undoubted inventor, is placed above the boiler A. In the cylinder I is a piston or float N made of thin plates of metal, forming a hollow cylinder which floats on the surface of the water. A pipe and stop-cock D is inserted in the cylinder I. When steam is generated by lighting a fire beneath the boiler A, the cock C is opened to allow it to rush into the pump cylinder I, which is nearly filled with water. The elastic force of the steam depresses the float *n n*, and thus forces the water beneath it through the valve O, and up the pipe OQ into the receiver RR, the air in which it of course condenses. The stop-cock *p* is then opened, and the water pressed out by the elasticity of the condensed air in the receiver rushes out through the cock P, and strikes the float-boards U, S, X, of a wheel which gives motion to any other machinery. When the float *n n* has descended to N, the farther admission of steam into I is prevented by turning the cock C, and the steam above the float is allowed to escape into the air by the cock D. At the same time the stop-cock M is opened to allow the water in the funnel K to descend and raise the float *n n* to its first position as in the figure. The cocks D and M are now shut, and C is opened to re-admit the steam from the boiler, and impel more water against the wheel, which will thus be kept in constant motion. A pipe and cock is placed at E to allow the air in the boiler to escape when it is first filling with steam. A similar pipe empties the pipe X of water.

In order to increase the force of the steam, Papin proposed to introduce a red hot heater, H through G, but this was a clumsy contrivance, of no value; and indeed the whole machine, though ingenious, could not be put in comparison with the previous invention of Savery.

Dr. Gravesende, having come to England as secretary to the Dutch embassy in 1716, went through a course of experimental philosophy with Dr. Desaguliers. When they were considering Savery's steam engine, it appeared to them that there was a great waste of steam by its continually acting upon the receiver without intermission, since it became useless till it had heated the surface of the water in the re-

* This does not mean impelling ships, but emptying them of water.

† "It does not appear," says Mr. Watt, "that the Marquis of Worcester knew any thing of the use of an injection, as the machine described by him operated only by the expansive force of steam, whereas the injection was used in Savery's engine from the beginning, and is in all probability his invention."—Robison's *Works*, vol. ii. p. 50, note.

ceivers. They therefore made a model which could work either with one or two receivers, and they soon found by it that, "one receiver could be emptied three times, while two succeeding ones could be emptied only once a piece." Hence they concluded, that such an engine would save a third more water, and be erected at only half the expense.

This ingenious contrivance is shown in plate DV, Fig. 1, where A is the receiver of copper communicating at bottom with the making and forcing pipes between E and G, and at top with the steam pipe at D, and the rejecting pipe at I. The boiler B, which is also of copper, contains at least five times more than the receiver, round which the fire and flame are conducted at T, T, T. It has a copper cover screwed, in which contains the steam pipe CD communicating from the boiler to the receiver, and guage pipes N *n*, O *o*, with a valve at P, kept down by the steelyard PQ and weight Q. The surface SS of the water in the boiler must be lower than the bottom of the short guage pipe at *o*, and higher than the bottom of the long one at *n*. The steam cock DI has its key K kept down by the screw L held by the arm DL, while the handle K is either turned to *k* to receive the steam issuing from the boiler, or to K to shut off the steam and admit a jet of cold water coming from the ascending pipe EE2 through the cock M, the mechanism of which is shown in detail in Fig. 2, where 1 is the screw which, passing through the stirrup 2, presses on the piece of cast iron 3, made tight to the brim under it by double canvas, while the returns of the stirrup draw up the ring 4 under the brim to support it; 5, 6, 7, shows the key of the stop cock with a hole on the side at 6, which passes down through the bottom of the key to throw down alternately into the receiver the steam and the jet or injection. There is a notch in the key at 7 to receive the water from the force pipe, and carry it to the boiler, when it receives a fresh supply of water. The annexed section of the steam cock and key will make its construction perfectly intelligible.

The horse or pipe EEGZ, with several elbows, is soldered at E to the forcing pipe EE2. The sucking pipe ZH is soldered to it at Z, and the receiver at F. This horse contains the sucking valve at G, and the forcing valve at F, which are easily got at by unscrewing 1 to loosen the strap 2, and let down the flanch 3, as shown in Fig. 2. The cistern R communicates with the forcing pipe by a cock and small branch Y to fill the forcing pipe when required. A spreading plate I is used to make the steam and the water be alternately divided into little jets, and *b c* represents the surface of the steam pushing down the water in order to drive it up again into the force pipe EE through the valve E. The door of the fire place is shown at V, and the ash hole at W.

This engine operates as follows. Take off the steelyard PQ, and open the cock O of the short guage pipe O *o*, then holding up the valve by a long nail, pour in water at the valve, which will blow out the air at O till the surface of the water rises above the bottom *o* of the guage pipe, when the boiler will be sufficiently filled. Having then stopped the communication between the steam cock DI and the boiler, and shut the two guage cocks at N and O, replace the steelyard on the valve with its weight O near P, and light the fire at T. As the fire is increased remove the weight Q, notch by notch, till it comes to the last notch at Q, and see that no additional weight is put to it.

When the steam begins to lift the safety valve P, and when the receiver A has been filled with water, which is done by taking out the key of the cock under the screw L, and opening the cocks Y and M, turn the handle of the steam-cock on the receiver from K to *k* to admit the steam from the boiler along CD, first opening it partially, and then fully. The steam will now spread through the small holes of the plate at I, and pressing on the surface of the water at *b c*, will force it through the valve F, and up the pipe EE. This pipe being now full, and the cock M open, turn back the handle from *k* to K, and a jet of cold water will spout through the spreading plate I among the steam, which it will immediately condense, and the air pressing on the water in the well at H will push it up into the receiver A, and will force it up I. The handle being turned to *k* as formerly, the steam will be again admitted, and will again draw the water up the pipe EE into the cistern R.

The engine will thus continue to raise water four or five hours, till both the guage pipes N and O give steam, which shows that the boiler requires a supply of water.

In order to replenish the boiler, turn from you the handle K behind L, which will bring the notch 7 of the key in Fig. 2, to the situation in the right hand section in Fig. 2, and then the cocks M and Y being still open, the water will flow from the cistern through the forcing pipe and steam pipe into the boiler without going into the receiver, the steelyard being off the valve, and the cock O open to let out the air as the water enters. Whenever the cock O ceases to blow, and the valve descends, turn back the handle to K, and shut the cock Y.

Some of Dr. Desaguliers' engines were erected after 1717–1718, and one of them was for the Czar, Peter I. for his garden at St. Petersburg. The water was drawn up by suction 29 feet high, and then forced up 11 feet higher. In another the water was drawn up 29 feet, and forced up 24 feet higher.

Various engines on the principle of Mr. Savery's have been erected since his time, and various improvements have been made on the original construction; and as there are many circumstances under which they may still be advantageously employed, we shall describe one which was erected by Mr. P. Keir at St. Pancras, and which was employed for many years to turn lathes, &c. The following description of it is given by Mr. Keir himself in Nicholson's *Philosophical Journal*.

The figure, Plate DV, Fig. 3, is a section of the engine, taken through the centre. B represents a boiler, shaped like a wagon, seven feet long, five feet wide, and five deep: it was considered as being of dimensions sufficient to work a larger engine; a circumstance which must, in a certain degree, diminish the effects of the present one. The boiler feeds itself with water from an elevated cistern, by a pipe which descends into the boiler, and has a valve in it, at the upper end, which shuts downwards, and is connected by a wire with a float on the surface of the water within the boiler, so as to open the valve whenever the water subsides below the intended level; for the float which swims on the water then sinks, and by its weight draws the valve up, to allow the water from the cistern to run down the pipe and supply the deficiency: but as the water in the boiler rises the float closes the valve. The boiler therefore remains constantly or nearly at the same degree of fulness.

The steam is conveyed by a pipe C to a box D through which, by the opening and shutting of a valve it can be admitted to the cylindrical receiver A. The axis K serves as a key to open and shut the valve, which is a circular plate, formed conical on the edge, and fits in a corresponding aperture in the bottom of the box D. H is a cistern from which the engine draws its water through a vertical suction pipe, in which a valve, G, is placed to prevent the return of the water. R is another cistern into which the water is delivered from the receiver A, through the spout F, which is provided with a valve opening outwards. WW represents an overshot water wheel eighteen feet in diameter, of which the axis S communicates motion to the latches and other machines used in the manufactory.

The engine raises the water from the lower cistern H, by suction, into the receiver A, from which it runs into the upper cistern R, and thence flows through a sluice into the buckets of the water-wheel W to give it motion. The water, as it is discharged from the buckets of the wheel, falls again into the lower cistern H. As the same water circulates continually in both the cisterns, it becomes warmer than the hand after working a short time; for which reason the injection water is forced up by a small forcing pump from a well. This injection pump is worked by the water wheel, by means of a loaded lever, or pump handle, which is raised up by the motion of the wheel, and then left to descend suddenly by its weight, and force up the water into the receiver. A leaden pipe passes from this forcing pump to the upper or conical part of the receiver A, for the purpose of injecting cold water at the proper time. Neither of these could be represented with convenience in the present section.

The manner in which the steam and cold water are alternately admitted into the receiver A, remains to be explained. Upon the extremity of the axis S of the water wheel, a solid wooden wheel T is fixed; it is about four feet in diameter, and turns round with the water wheel. It is represented separately, as seen in the front; *a*, *b*, *c*, *d*, are four cleats, all or any number of which may be fixed on the wheel at a time. Each cleat has its corresponding blocks *e*, *f*, *g*, *h*, on the opposite surface of the wheel. The use of these is to work the engine. Thus, suppose the water wheel, and this wheel T, with all the revolving apparatus, is turning round, one of the cleats *a* meets in its rotation with a lever, which it lifts up, and this opens the steam valve D by a rod of communication reaching to the handle of the axis K. The steam consequently passes into the receiver A, and the steam valve shuts again, as soon as the cleat *a* of the wheel T has passed away from the lever by the motion of the wheel. All this time the corresponding block *e* on the other side of the wheel T had been operating to raise up the loaded lever which forms the handle of the forcing pump: and at the same instant that the steam valve D is shut, as above mentioned, the block *e* quits the loaded lever, after having raised it up, and leaves it to descend suddenly by its own weight. This depresses the forcer of the pump and thereby throws a jet of cold water up into the receiver A, and it falls in a shower of drops through the steam which fills the receiver, so as to cool and condense the steam and make a vacuum.

The pressure of the atmosphere upon the surface of the water in the cistern K then causes the water to mount up the perpendicular suction-pipe, through the valve G, towards the exhausted receiver.

When the engine is first set to work, the water-wheel being motionless, the steam valve and injection pump are moved by hand, and if the engine has been long out of work, two or three strokes may be necessary to raise the water to the top of the receiver A, so as to fill it full of water. As soon as this is the case, and the steam valve is opened to admit steam into the receiver, the whole contents of water, above the spout and valve F, then flows out of the receiver A, by its own gravity, into the upper cistern R.

The water which is thus raised, is suffered to flow from the cistern upon the overshot water wheel W through a sluice; and by that means keeps the wheel in motion, and replenishes the lower cistern. There is no reservoir for the injection water; but the requisite quantity is driven up at each stroke; and as this is done by the sudden descent of the loaded lever of the pump, the water is injected very suddenly into the receiver."

Before the improvements upon Savery's engine were proposed by Desaguliers, a very important invention had been made by Mr. Thomas Newcomen, an ironmonger in Dartmouth. There is reason to believe that this ingenious workman was occupied in the improvement of the steam engine as early as Mr. Savery. Switzer, indeed, who was a friend of Savery's, and therefore not likely to make any statement injurious to his reputation, distinctly informs us that he had good authority for stating that Newcomen was as early in his invention as Savery; but that the latter being nearer the Court, obtained his patent before the other knew of it, on which account Newcomen was glad to come in as a partner in the patent which was granted to them in 1705.

Dr. Desaguliers, however, has given a different account of the matter, and as the passage contains some interesting details, we shall give it in his own words. " Thomas Newcomen, ironmonger, and John Calley, glazier of Dartmouth (Anabaptists) made the several experiments in private, and having brought the engine to work with a piston, &c. they, in the latter end of the year 1711, made proposals to draw the water at Griff in Warwickshire; but their invention meeting not with reception, in March following, through the acquaintance of Mr. Potter of Bromsgrove in Worcestershire, they bargained to draw water for Mr. Bach of Wolverhampton, where, after a great many laborious attempts, they did make the engine work; but not being either philosophers to understand the reasons, or mathematicians enough to calculate the powers, and to proportion the parts, very luckily by accident found what they sought for. They were at a loss about the pumps, but being so near Birmingham, and having the assistance of so many admirable and ingenious workmen, they so soon came to the method of making the pump valves, clacks, and buckets, whereas they had but an imperfect notion of them before."

The engine thus constructed has received the name of the atmospheric engine, in consequence of the power which is employed, being only the weight of the atmosphere, the steam exerting no force whatever either upon the surface of the water, or upon the piston, and having no other functions to perform but that of forming a vacuum. Newcomen's engine, in its original state, is shown in Plate DV; Fig. 4. The steam generated in the boiler B, passes through the cock D into the steam cylinder A, beneath a piston S, which is attached by means of the piston rod *r*, to the great beam I, I. This beam or lever has at its extremities arch heads, upon which the chain R laps and unlaps itself during the motion of the beam round the fulcrum C, the chain being fixed at the upper end of the arched head. The cylinder A is surrounded with another cylinder ZZ, concentric with it, and communicating by a pipe F, with a reservoir G of cold water, while its lower end communicates with the well O, by another pipe EE.

The piston being at the top of the cylinder, as shown in the Figure, let steam be admitted into the cylinder till it is full. When this is done, turn the cock D to prevent the entrance of any more, and open the cock F, to allow cold water from G to flow into the outer cylinder ZZ. By cooling the steam cylinder A, this will condense the steam within it, which will form a vacuum under the piston S. The whole weight of the atmosphere, which now presses on the upper side of the piston, having no force on the other side to counterbalance, it will force the piston S down to the bottom of the cylinder. By this means, the end I of the great beam is depressed, and the opposite end I′ raised, so as to work the pump L, and raise the water which it contains. When the piston has reached the bottom of the cylinder, the cock F is shut, and the cock E opened, and the water in the outer cylinder ZZ, descends into the well O, while the small quantity formed by the condensation of the steam in A, descends also into O through the pipe P. By means of a counter-weight M, placed on the rod K, the piston S is brought up to the top of the cylinder, and steam being again admitted, and again condensed as already described, the piston is again forced down, and a fresh draught of water brought from the well L. The fire beneath the boiler is shown at N, the ash-pit at W, the flues at XX, and the pipe which supplies the reservoir G at TT. The mouth of the well or mine to be drained, is shown at L, and H is a pipe for admitting water above the piston, to keep it water-tight.

Such was the state of the atmospheric engine before March 1712, when the patentees, as above stated, obtained such important aid from the Birmingham artists. But an accident now occurred which turned out of great importance. Having observed the engine perform several strokes in very quick succession, they found, upon a strict examination, that there was a hole in the piston, which let the cold water in to condense the steam in the inside of the cylinder, whereas this had always been done on the outside. Hence arose the use of the injection pipe, which was afterwards made to squirt a jet of water upwards from the bottom of the cylinder into the steam which it contained. The outer cylinder ZZ, was therefore no longer necessary, and the pipe *f* entered the bottom of the cylinder, as shown in Fig. 5.

Dr. Desaguliers remarks, "that they used to work with a buoy in the cylinder, enclosed in a pipe, which buoy rose when the steam was strong, and opened the injection, and made a stroke, thereby they were capable of only giving six, eight, or ten strokes in a minute, till a boy, Humphry Potter, who attended the engine, added (what he called *scoggan*,) a catch, that the beam Q always opened, and then it would go fifteen or sixteen strokes in a minute. About this time (in 1713) the leathering of the piston was found out by accident. "Having then screwed a large broad piece of leather to the piston, which turned up the sides of the cylinder two or three inches; in working it wore through, and cut that piece from the other, which falling flat on the piston, wrought with its edge to the cylinder, and having been in a long time, was worn very narrow; which being taken out, they had the happy discovery, whereby they found that a bridle rein, or even a soft thick piece of rope or match going round, would make the piston air and water-tight." A few years afterwards, in 1717, Dr. Desaguliers communicated to Mr. Beighton the use of the steelyard safety valve.

Notwithstanding these great improvements, the mechanism of the steam engine was still very imperfect. The necessity of cock buoys to open and shut the cocks, and the number of catches and strings employed gave a character of complexity to its parts, which rendered them liable to derangement from the slightest irregularity. All this apparatus, however, was superseded in 1818, by the invention of what is called hand-gear, which Mr. Henry Beighton, an able engineer, first applied to an engine which he erected at Newcastle-upon-Tyne. In this engine, the cocks were all opened, and that by the hand-gear, which was put in motion by a rod suspended from the main beam. Mr. Beighton made also several other changes upon the engine, which improved the form and arrangement of its parts, and he introduced a neatness and accuracy of workmanship unknown to his predecessors.

The steam engine as constructed by Mr. Beighton, is shown in Plate DV. Fig. 6, where *h h* is the great beam, C the cylinder, A the fire, and B the boiler, all of which act in the manner already described. The part which we intend principally to describe, is the working perpendicular beam QQ, with all its machinery for opening and shutting the regulator and injection cock. This machinery is contained within the compass of the letters D *d* C 6 P 5 4 1 Q N F E, but its parts are here on such a small scale, that we have given them separately in Fig. 7. Between two perpendicular pieces of wood on each side of P, Fig. 6, and marked AB in Fig. 7, there is a square iron axis AB, which carries four iron pieces necessary for turning the regulator, by pushing forward and drawing back the fork fastened to the handle of the regulator Fig. 6, and marked QOEL, Fig. 7. In the beam QQ, there is a slit so contrived that its pins work on the fore part, middle, and back part, to raise and depress the levers 5, 4, that move the axle AB, as far about its centre as is necessary. A piece CED called the Y moves round AB on an axis, and carries a weight F, which by means of a key and wedge can be slipped along the arm C. By means of a hooked stirrup GLE, the axle AB is joined to the horizontal fork ON. A spanner or handle G 4 is driven on upon the axle AB; and another shorter spanner H 5, at half right angles to this, is forced on to where it is made fast. When the working beam QQ rises, the pulley *p* will lift up the spanner H 5, which turns the axle AB so far round as to throw the Y, CED with its weight F from C to 6, in which direction, after passing the perpendicular, it would continue to move towards O, if it were not stopped by a strap of leather fixed to its top at Œ, and made fast at the points *m*, *n*, in such a manner as to allow the Y to vibrate about a quarter of a circle in falling forwards and backwards after it has passed the perpendicular. The horizontal fork ON is joined at its end O to the spanner or handle of the regulator P 9 Q 10, there being several holes in these pieces, that any part of the end O may be kept in any part of the slit in the spanner, as may be necessary for the better motion of the two pieces. The other end N of the fork is fastened to the bottom EKNL of the stirrup by the long horizontal pin L, so that the fork may continue horizontal as it is pushed forward and drawn back by the spanner P 10, to shut and open the regulator in the manner to be afterwards described. There is a horizontal piece *u l* so placed that the end 10 of the spanner may bear upon it, and be supported as it slides backwards and forwards.

The situation of the machine as represented in Fig. 7, is as follows. The regulator is open, as appears by its plate TY, being removed from under the communication or throat pipe SS that goes into the cylinder. The piston is now at the place CW, Fig. 6, at the top of the cylinder, and consequently the great beam *h h* and the working perpendicular beam QQ are now almost at their utmost height: And the pulley P in the slit of the working beam has so far raised the spanner *h* 5 that the weight F is brought so much from beneath N as to be past the perpendicular over the axle AB; and being ready to fall over towards N, it will with a smart blow of its shank E strike the pin L, and drawing the fork OL horizontally towards the working beam, will draw the end 10 of the handle of the regulator towards *l*, and then shut it by slipping the plate Y under the pipe SS. In Fig. 6, the blow is already struck, as may be seen by observing that the weight at the head of the Y has got to 6, as far as the strap P 6 (or *n* 6 in Fig. 7.) will let it go.

When the regulator is shut, the next thing is to open the injection cock to produce the vacuum, and immediately to shut it when the piston begins to come down. The part of the pipe coming from the injecting cistern is shown at *o*, Fig. 7, and *c* is the part that leads to the cylinder, *e* is the key of the cock which has a narrow long upright hole, instead of a round one, that it may be the sooner opened. On the top of this key there is fastened a quarter of a toothed wheel *l*, turned by another quarter of a toothed wheel *i* hanging down from the axis *h g*, which is moved by the lever *h k*, commonly called the F.

As soon as the regulator is shut by the ascent of the pulley *p*, the beam QQ not immediately losing its motion upwards, the pin *s* on its outside lifts up the extremity 1 of the F, 1 *k h*, and opens the injection cock; and the jet immediately making a vacuum, the beam begins to descend, and the pin *r* which can be put higher or lower, depressing the F shuts the injection cock; while the beam QQ continuing to descend, the pulley *p* pressing on the handle C 4, throws back the Y, whose shank D throws forward the fork and opens the regulator to admit fresh steam in the way formerly described, which steam is shut off by shutting the regulator till the injecting cock is again opened.

In the engine represented in Fig. 6. there is a strong frame F 1 F 2, upon which fill two strong wooden springs S 1 S 2, that if the arch of the great beam *h h* should come down too low, no mischief may be done to the piston, and the whole stroke may be made upon S 1 S 2 by the strong iron pins P 1 P 2, which will there be stopped. The pump which the engine is to work, is shown at *p*, the pump rod at *i*, and *k* is the rod of another pump which raises some of the water at *p*, by the injection reservior *g*, through a pipe which passes by *o*, and behind the attendant *c*.

Hitherto the steam employed as a mechanical power had been reconverted into water by condensation; but about the year 1720, Leupold, the author of the *Theatrum Machinarum*, suggested the plan of blowing it out into the atmosphere, and may therefore be considered as the inventor of the high pressure engine. This engine is shown in Fig. 1 of Plate DVI, where A is the boiler communicating by the *four* way cock X with the lower ends of two cylinders R,S, in which two pistons C,D move up and down, and put in motion two levers G,H by the intervention of the piston rods, E,F. Pump rods K,L, fixed to the other ends of these levers, work the pumps O and P, and raise the water up the main pipe Q. The fire-place is shown at Z, and the ash-pit at Y. The levers G,H move upon pivots I,I, and the four way cock X is so constructed as to shut off the communication between the boiler A and either of the cylinders R,S, while it opens a communication with the external air. The operation of the engine is as follows.

The steam from the boiler A being admitted through the passage 3 into the cylinder R, forces the piston C up to the top, and thus depresses the pump rod K, which forces the water up Q. When C is at the top, the cock X is turned, and the passage B between the boiler and the cylinder closed, while a communication is opened from the inside of the cylinder into the atmosphere. The weight of the piston and piston rod FG, being made greater than that of K and O, the piston C will fall to the bottom of the cylinder, driving out the steam that had remained in it From the construction of the cock X a passage is opened between the boiler A and the other cylinder S, when the passage into R was closed. Hence the piston D is forced upwards, and the pump rod of the pump P descends and forces water up Q. The cock X being again turned, the steam is shut off from S, and a passage open into the external air, so that the weight of ED being greater than that of LP, the piston D will descend and press out the steam into the atmophere.

No attempt had yet been made to convert the reciprocating motion of the piston into a continuous rotatory motion: but Mr. Jonathan Hulls, who in 1736 proposed to apply the steam engine to tow vessels or ships into and out of harbour, described a contrivance by which the rise and fall of the piston should give a continued rotatory motion to the paddle wheels, but the proposal excited no notice; and his steam boat as well as his rotatory mechanism,* were left as a legacy to his successor. See our article Steam Boat.

* Mr. Robert Stuart, in his excellent *Descriptive History of the Steam Engine*, p. 83. Lond. 1824, seems to us to have committed a serious mistake in ascribing the invention of the *crank* to J. Hulls, and thus depriving Mr. Watt of the honour of an invention which he had considered so completely his own as to secure it by a patent. "*In this scheme*," (meaning

In the year 1756 a patent was taken out by Mr. Blakey, for a contrivance which prevented the steam from coming in contact with the water, as in Savery's engine. One of his contrivances consisted in interposing a quantity of oil between the steam and the water. He employed also two receivers or cylinders, the one placed above the other, so that the water beneath the oil might not be changed at each injection. Another contrivance was to interpose air in place of oil; but none of these were found to answer in practice, and Blakey's engine never attained any celebrity. In principle, indeed, it was the same as Savery's. At a much later period, viz. in 1775, Mr. Blakey made an important improvement in the boiler, whereby much fuel is saved. Three cylindrical vessels were placed, the one above the other, as shown in Fig. 2. Plate DVI, and connected so as to constitute a boiler. It is then surrounded with the fire, and the steam let off by the cocks shown in the figure.

In the year 1757 Mr. Keane Fitzgerald communicated to the Royal Society of London, a paper entitled *An attempt to improve the manner of working the ventilator by the help of the Fire Engine.** "As the lever of the fire engine works up and down alternately, and performs at a common medium about a dozen strokes in a minute, it was necessary to contrive some way to make the beam, though moving alternately, to turn a wheel constantly round one way, and also to increase the number of strokes to 50 or 60 in a minute. The model of a machine for this purpose, is composed of four wheels of different sizes, two clicks, three pinions and a fly, which is put into motion by the part of a wheel fixed to the arch of a lever of the fire engine. The wheel which is turned by the lever, or rather moved up and down by it, is loose on its arbor, and likewise one of the ratchets, and the wheel next to it. The outside ratchets and outside wheel are fixed on the arbor. There are two pinion wheels fixed on the arbor, one on each side near the edge of the wheel moved by the lever which turns them. There are also two clicks, one fixed to the great wheel, the other to the frame. These are exclusive of the wheel that moves the fly.

The effect is, when the lever moves the wheel downwards, its click forces the ratchet fixed on the arbor to move along with it, and the other wheels the same way. When it moves upwards, the click fixed on the frame stops the larger ratchet, and the wheel next to it, which are pinned together. This wheel being stopped, and the great wheel carried upwards by the lever, the pinion towards the edge of the great wheel is forced round it, and moves the pinion on the other side of the great wheel, which pinion moves the wheel fixed on the arbor the contrary way to the great wheel, which is carried upwards by the lever. By which means the arbor is constantly turned the same way, when the lever of the fire engine is moved either upwards or downwards.

Upon the arbor, there is also another great wheel fixed, which turns a pinion, on the arbor of which pinion is a crank to move the ventilator, and also a fly fixed to the end, to help the motion of the crank, which, in the model, is turned three times for each stroke of the lever, and may be increased or diminished according to the number of teeth in the pinion. The number of teeth in the great wheel moved by the lever is 66, but need not have teeth above half way round. The wheel fixed to the ratchet has 33 teeth, and its pinion 11. The wheel fixed on the arbor on the outside has 24 teeth, and its pinion 16. The wheel which turns the fly has 90 teeth, and the pinion turned by this wheel 10. The greater the number of teeth in the ratchets the better. This machine may also be applied to other useful purposes at mines, and may easily be made to turn a mill, to grind corn, or to turn a wheel to raise coals, or whatever else is wanted to be raised from the mines."

Dr. Robison had, without due consideration, regarded this contrivance of Mr. Fitzgerald as involving the invention of the crank, with which Mr. Watt had afterwards converted the vertical motion of the piston into a rotatory motion, and had therefore deprived Mr. Watt of that honour. Mr. Watt, who, as it will afterwards be seen, had been particularly harassed regarding the subject of the crank, corrected to a certain degree this error in his annotations on Dr. Robison's paper; but in a letter which he wrote to Dr. Brewster, dated February 23, 1814, he speaks still more decidedly: "Dr. Robison," says he, "mentions, that Mr. Keane Fitzgerald published in the Transactions, 'a method of converting the reciprocating motion of the steam engine into a continued rotatory motion, by means of a crank, or a train of wheel work,' and adds, in sec. 52, 'by this contrivance he hoped to render it of most extensive use, and that he, and others associated with him, obtained a patent for it. They also published proposals for erecting mills of all kinds driven by steam engines, and stated fairly their powers and their advantages.'

"Now, I find, (continues Mr. Watt,) in the *Philosophical Transactions*, vol. 50, part ii, an invention by Mr. Fitzgerald for working ventilators by means of a steam engine, in which the rotative motion is produced by a train of wheelwork, which *ultimately turns a crank*, which works the ventilators, *a very different thing from a rotatory motion produced by the inter-*

Hull's,) says Mr. Stuart, "*it was necessary to convert the alternate rectilineal motion of a piston rod into a continuous rotatory one*, and which he ingeniously suggested might be accomplished by means of a *crank*. This is now with justice considered that invention which introduced the steam engine as a first mover of *every variety of machinery*. Hulls was unable to interest the public in his project; and his mode of applying the crank was so completely forgotten, that at its revival about forty years after this period, a patent was obtained for the invention, and the merit of the application was also claimed by the celebrated Mr. Watt, evidently without any knowledge of Hull's suggestion." In Hulls' method the rotatory motion is effected by ropes and wheels, as will be seen in the drawing which will be given under our article STEAM BOAT, and no crank is ever mentioned. It is true that Hulls afterwards says, "up inland rivers, where the bottom can possibly be reached, the fans may be taken out, and *cranks placed at the hindmost axis to strike a shaft to the bottom of the river, which will drive the vessel forward with the greater force.*" But this cannot by any stretch of criticism be considered as the conversion of a reciprocating into a rotatory motion by means of a crank. Had Hulls once got hold of the idea of applying the crank in this way, he would never have adopted the other contrivance, the exposure of which to injury by the sea, he obviously considers as an objection. Mr. Watt must therefore be allowed the great merit of the application of the crank to convert the vertical motion of the piston rod into a continued rotatory motion.

* *Phil. Trans.* 1758, p. 727.

vention of a crank! As to the mill scheme, we can find no trace of it, nor of the patent; and being a matter of some consequence to clear up, I have written to some friends in London about it, but have yet received no answer. I shall thank you, if you cannot otherwise find out the matter of fact, to get a search made among Dr. Robison's memoranda, to learn upon what authority he made the assertion. If nothing more is learned about it, I must conclude the note to be a mistake, and comment upon it accordingly." No record of a patent was found at the public offices, and Mr. Watt accordingly made those alterations, &c. on Dr. Robison's paper, which are already before the public."

It is impossible to pass over this statement respecting the crank, without calling the attention of the reader to the annoyances to which an inventor is exposed by the rash decisions and criticisms of his friends. If Dr. Robison and Mr. Stuart, men of talents and character, and great admirers of Mr. Watt, have, under a sense of justice, attributed one of his finest inventions, the one to Mr. Fitzgerald, and the other to Jonathan Hulls, without any other foundation than the recommendation of a crank, as part of the machinery, it is not to be wondered at that writers of inferior judgment and integrity should so often commit the same mistake. To this species of persecution, Mr. Watt has been particularly exposed, and yet the whole history of science does not present to us an individual whose inventions were more original, and to which less approach had been made by the ingenuity of his predecessors.

When Mr. Watt's attention was turned to the subject of steam in 1759, it was then an effective and useful machine, and was used to a considerable extent in the mines and manufactories of the kingdom; but though it was then an effective machine, it was a very imperfect one, and required for its improvement all the energies of a mind deeply imbued with mechanical and chemical knowledge. In the year 1761 or 1762, Mr. Watt had constructed a model, with which he showed the practicability of what is now called the high pressure engine; but it was not till 1763, when he was repairing a model of Newcomen's engine, belonging to the college of Glasgow, that his mind was usefully directed to the subject. Having repaired it merely as a mechanician, he found, upon setting it to work, that its boiler, though apparently quite large enough,* could not supply it with steam. This he found to be caused by the small cylinder exposing a greater surface to condense the steam, than the cylinders of larger engines did in proportion to their respective contents. The cylinder of the model also, which was of brass, conducted heat better than the cast iron cylinders of larger engines, (generally covered on the inside with a stony crust) and hence Mr. Watt conceived the idea of making this cylinder of wood baked to dryness, and soaked in linseed oil. He soon found, however, that the steam which was condensed in filling it exceeded the proportion of that required for large engines, according to Desaguliers. This effect Mr. Watt ascribed to the fact (newly discovered by Dr. Cullen and some other philosophers) that water boiled in vacuo at heats below 100°, because at greater heats the water in the cylinder would generate steam, which would contribute to resist the pressure of the atmosphere.

In the progress of his experiments, Mr. Watt ascertained that *one* cubic inch of water formed about a cubic foot, or 1728 cubic inches of ordinary steam, and that the condensation of that quantity of steam would raise *six* cubic inches of water from the temperature of the atmosphere to the boiling point. Hence he concluded that six times this rise of temperature, or about 800° of heat, had been actually employed in the conversion of the water into steam, and all of which must be withdrawn before a perfect vacuum could be formed under the piston. Struck with this remarkable fact, and not understanding the reason of it, he mentioned it to his friend Dr. Black, who then explained to him his doctrine of latent heat, which he had for some time before this (summer of 1764) taught in the university.

Mr. Watt now perceived that, in order to make the best use of steam, two things were necessary. First, to maintain the cylinder as hot as the steam which entered it; and secondly, to cool down to 100°, and lower, if possible, the water produced from the condensation of the steam, and the injection water itself. The means of accomplishing these two leading objects did not immediately present themselves, but early in 1765 it occurred to him that if *a communication were opened between a cylinder containing steam, and another vessel exhausted of air and other fluids, the steam would immediately rush into the empty vessel, and continue to do so till it had established an equilibrium, and if that vessel were kept very cool by an injection or otherwise, more steam would continue to enter until the whole was condensed.* Thus did Mr. Watt discover the great principle of *condensation in a separate vessel;*† but in its application he had to contend with difficulties which required new resources. As both the vessels were exhausted, or nearly so, how was the injection water, the air which would enter it, and the condensed steam, to be got out. This he proposed to effect in two ways: one of these ways was to adapt to the second vessel a pipe reaching downwards more than 34 feet, by which the water would descend, (a column of that length overbalancing the atmosphere) and by extracting the air with a pump. The second way was to employ one or more pumps to extract both the air and the water, which would be applica-

* The boiler was *nine* inches in diameter, and the cylinder *two* inches in diameter, with a stroke of six inches.

† The invention of a separate condenser has been strangely though indirectly ascribed by Mr. Hornblower to the Rev. Mr. Gainsborough, and this is said to have taken place *about the time that Mr. Watt was engaged in bringing forward the improvement of the engine.* This is in reality an acknowledgment of Mr. Watt's priority, for Mr. Watt did not bring forward this great improvement till long after it was made. In the Review (*Edinburgh Review*, 1809, *p.* 328,) of Dr. Gregory's Mechanics, (vol. ii. p. 362,) where Mr. Hornblower's History of the Steam Engine appeared, (an article which Mr. R. Stuart has erroneously ascribed to Dr. Brewster) it is stated, and we believe with perfect correctness, that Mr. Gainsborough's idea was *twenty years posterior to Mr. Watt's.* This claim, in behalf of Mr. Gainsborough, urged neither by himelf nor by any of his friends, but by one of Mr. Watt's avowed enemies, must be considered as establishing Mr. Watt's original and undivided claim upon an impregnable basis

ble in all places, and essential in those cases where there was no well or pit. Mr. Watt preferred and invariably used the latter method.

In order to lubricate and keep the piston steam tight, Mr. Watt employed wax tallow or any other grease. This was effected by Newcomen, by having water above the piston; but when any of it entered the partially exhausted and hot cylinder it boiled, and prevented the production of a vacuum, besides cooling the cylinder by its evaporation during the descent of the piston. As the mouth of the cylinder was open, Mr. Watt found that the air which entered to act on the piston cooled the cylinder, and condensed some steam in again filling it. He, therefore, proposed to put an air-tight cover on the cylinder, through which cover there was a hole with a stuffing box for the piston rod to slide through; and when this suggested itself, it immediately occurred to him *to admit the steam above the piston*, to act upon it instead of the atmosphere. Another source of the loss of steam still remained, namely, the cooling of the cylinder by the external air, which would occasion at every stroke an internal condensation whenever the steam entered it. Mr. Watt proposed to provide against this, by placing the working cylinder within another cylinder containing steam, and to surround this by another of wood or of some bad conductor of heat. "When once," says Mr. Watt, "the idea of the separate condensation was started, all these improvements followed as corollaries in quick succession, so that in the course of one or two days the invention was thus far complete in my mind; and I immediately set about an experiment to verify it practically.

This experiment succeeded perfectly, and confirmed Mr. Watt's highest expectations. He therefore applied in 1768 for letters patent for "*methods of lessening the consumption of steam, and consequently of fuel in steam engines*, which passed the seals in January 1769. The specification recited *seven* different principles, viz.

1. To keep the steam cylinder as hot as the steam which enters it.

2. To condense the steam in separate vessels, to be kept as cold as the adjacent air by water or cold bodies.

3. To draw the air or vapour out of the cylinder, and condense by pumps wrought by the engine.

4. To employ the expansive force of steam to press upon the piston; and in cases where cold water is not plentiful, to work the engines by this force of steam only by discharging the steam into the open air after it has done its office.

5. Where rotatory motions are required, to make the steam vessels in the form of hollow rings, with inlets and outlets for the steam, mounted on horizontal axles.

6. To apply a degree of cold to contract the steam, so that the engine may be wrought by the alternate contractions and expansion of the steam.

7. To render the parts of the engine, air, and steam tight, by using oils, wax, resinous bodies, fat of animals, quicksilver, and other metals in a fluid state.

While this patent was passing through its different stages, Mr. Watt was engaged in experiments with an engine which, with the assistance of Dr. Roebuck, who had purchased part of his patent right, he had erected at a coal mine near Borrowstounness. It had a cylinder 18 inches in diameter, and was successively altered and improved so as to embody several of the principles above mentioned. When these experiments were finished, Mr. Watt and Dr. Roebuck began their arrangements for manufacturing the engines on a great scale, but pecuniary difficulties prevented Dr. Roebuck from giving the most necessary aid, and he accordingly, in 1773, with Mr. Watt's consent, resigned his share in the patent to Mr. Matthew Bolton, a man of generosity, enterprise, and talent, and every way fitted for bringing into action the talents and inventions of Mr. Watt.

The extent of the arrangements, and the length of time necessary to bring the improved steam engine before the public, were soon discovered by experience, and Mr. Watt saw that it was impossible to reimburse himself for the great outlay which these arrangements rendered necessary during the few years of his patent which had yet to run.

He therefore applied to parliament in 1774 for an extension of the term of his patent; and with the zealous aid of Mr. Bolton, Dr. Roebuck, and Dr. Robison, he obtained in 1778 the exclusive privilege of manufacturing his improved engine for the space of twenty-five years.

About that time Mr. Watt and Mr. Bolton commenced a partnership for the manufacture of the improved engine, which continued till the expiry of the exclusive privilege in 1800. At their establishment at Soho near Birmingham, many admirable engines were soon made; and erected in Staffordshire, Shropshire, Warwickshire, &c. and Messrs. Watt and Bolton granted licences to use their engines, on the condition of securing *a third part of the saving of coal*, compared with an atmospheric engine performing the same work with coals equal in quantity. The amount of this saving was determined by ascertaining experimentally the coals consumed during any number of strokes made by the common and the improved engine. The number of strokes made in any given interval was ascertained by a piece of machinery called the *counter*, which was struck at every ascent of the working beam. Two keys of this machine were kept, one by the patentees, and the other by the proprietors; and a traveller who examined it at stated times, calculated the saving of coal from the number of strokes.*

These different inventions of Mr. Watt we shall now proceed to describe in their order.

Description of Mr. Watt's Single Reciprocating Engine, as constructed in 1788.

This engine is represented in Plate DVII. Fig. 1. The cylinder is shown at A surrounded with its steam case E. The cylinder, which is truly bored, is closed at its top by a cover, in the centre of which is the stuffing box D, through which the piston rod C moves. This stuffing box is constantly supplied with melted tallow, and the piston rod being turned to a true cylinder, no steam can escape. The piston B is also

* For three large engines erected at Chacewater mine in Cornwall, the proprietors paid £800 annually instead of the third of the saving of coal. Hence the saving of coal in using the three engines must have been $3 \times 3 \times 800 = £7200$ annually.

made steam-tight, and for this purpose it is supplied with melted tallow, through a funnel in the top of the cylinder. The boiler for generating the steam is shown at the left hand side of the engine, where *n* is the boiler, *p* the grate, and *o o* the flues on the side of it, *r* the damper, *s* the chimney, *t* the feed-pipe by which the boiler is supplied with water, and 1, 2, the guage-cocks. The steam pipe F proceeding from the boiler, and passing through the well, conveys the steam to the upper steam nozzle or valve G, through which it enters by the horizontal passage above the piston, and presses it, by its elastic force, down to the bottom of the cylinder. The perpendicular steam pipe which conveys the steam from the top of the cylinder into the bottom of it is shown at I. K is the equilibrium valve or nozzle, or the lower steam valve, which admits the steam below the piston, through the curved horizontal passage, to the left of L. When the valve is open there is an *equilibrium* between the steam entering both above and below the piston, from which circumstance it derives its name. J is the eduction pipe by which the steam is conveyed from the cylinder to the condenser M, which is a cylindrical vessel surrounded by cold water. N is the injection cock, which admits a jet of cold water from the cistern to condense the steam in N. At O is seen the termination of a copper pipe, called the *Snift* or *Blow-valve pipe*. It reaches to the outside of the cistern, and has its orifice closed with a little valve opening outwards and immersed in a small vessel of water. The object of it is to discharge the air from the vessels when the engine is first set a going.

P is the air pump, communicating with the lower end of the condenser by means of the valve R, which by the action of the air pump opens to allow the water and air to escape from the condenser, but closes in order to prevent either of them from returning.

m is the upper valve or discharging spout, opening outwards, which conveys the air and hot water into the hot well, from which the boiler is supplied with water by the means of the hot water pump U U, and pipe *u*, the continuation of which to the boiler is not shown.

V is the injection or cold water pump, which, rising from a tank without the engine-house, supplies water for cooling the condenser, and supplying the injection.

Z is the plug-tree or beam which drives the working gear Y of the nozzle and regulator valves.

a is the main lever or working beam, made of oak, and moveable upon its gudgeon or centre of motion *b*, which is fixed to the upper side of the beam by iron straps.

d is a king-post, from the top of which iron straps *c c* extend diagonally to each end of the beam, so as to form a truss.

Two iron catch pins, not seen in the figure, are fixed on the arched heads *e*, *f*, to strike upon the springs *β*, *β*, in order to limit the downward excursions of the pistons.

g, *f*, and *e*, are three arch heads fixed to the main beam. The arched head *g* is double, the one on the other side, not being seen in the figure. The one is to receive two chains, by which the plug tree Z is suspended, the rods from the two chains being joined and connected with the upper extremity of the plug trees, while the piston rod S of the air pump P is fixed to its lower extremity. The plug tree is kept steady by a horizontal bar fixed across it at its lower end, the two extremities of which slide in the vertical grooves of two upright posts. Three projecting pieces of wood, two of which are shown at *π π*, are fixed to the plug tree to give motion to the intermediate handles of the working gear.

e is the arched head for receiving the chain *f*, which carries the piston rod *h*, and piston *i* of the pump *j* having a clack valve at *p*.

Operation of Mr. Watt's Single Reciproeating Engine.

The engine is supposed to be at rest, and its valves shut, and all the parts brought into the position shown in the figure, which is effected by the preponderance of the pump rod *h*.

When the steam is generated in the boiler *n*, the three valves, G, K, and L, are opened by relieving the handles from their catches and the steam rushes through them above and below the piston, and into the condenser. The cold metal at first condenses it, but as the different parts become hot, all the above cavities are occupied with elastic steam, which displaces the air, and drives it all out at the blow valve O, an operation called *blowing* through, the completion of which is indicated by a smart crackling noise at the blow valve O, arising from the condensation of the steam by the cold water, when the air is all discharged. When this has been repeated two or three times, the valves G, K, L, are shut, and the farther admission of steam prevented. The steam remaining in the condenser will be speedily condensed, especially when a jet from the injection pipe has been thrown into it; but the cylinder both above and below the piston J will be occupied with steam.

If we now open the valves G, L, and N, Plate DVII, Fig. 1, by allowing the two handles at Y to rise, the steam will pass through G to the top of the piston, and, at the same time, the steam below the piston will escape through L into the condenser, while a jet of water from N will condense the steam, and producing a vacuum beneath the piston B, will allow the elastic force of the steam above it to press it to the bottom of the cylinder. The pump bucket *i* will be drawn up, and a column of water raised in its barrel *j*. When the piston B has descended half way down the cylinder, the upper piece of wood *π* strikes the *expansion handle* Z, and forcing it down, shuts the valve G, and excludes the steam, so that the piston performs the other half of its descent by the expansion of the steam already admitted above it. When the piston is at the bottom of the cylinder, another piece of wood on the opposite side of the plug tree presses down the middle handle above Y, which closes the *exhausting* valve L, and also the injecting valve, by means of a strap and rod connected with it. At the same time, the equilibrium valve K is opened by the working gear, so as to occasion an equilibrium in the state of the steam above and below the piston.

In this state of things the counter weight of the great piston rod will, by its preponderance, descend in its barrel, and cause the piston B to rise in the cylinder. When the piston B has risen half way up, the equilibrium valve K closes; and when the piston is quite at the top, the exhaustion valve L, the injection valve N, and the expansion valve G, are all opened by the action of the catches upon the handles of the working gear.

The steam consequently again rushes through G to the top of the piston, while the steam beneath it escapes into the condenser, where it receives the jet of the injection, and is converted into water, again creating a vacuum beneath the piston B, and in the condenser. The piston B consequently again descends, and the engine continues to act in the same manner, and thus to work the pump *h j*.

The air pump P does not begin its operation till the water of condensation and the injection water have accumulated. When this is the case, this water, flowing through R, rises above the piston Q through its valve; whenever it is at the bottom of the cylinder P, and the valve closed upon it, and preventing its descent, it is raised and discharged through the valve S into the hot well. In like manner, if there is any air or vapour in the condenser, it will help to press the water through R, and will itself escape through the valve in the box Q, when all the water has been discharged at S.

The *hot-water pump* UU, which enters the hot well, forces the water from it along the tube *u* and feeding pipe *t*, to supply the boiler *n*, so that there must be a saving of fuel by using this hot water in place of cold water.

Although we have mentioned generally the construction of the plug tree, and the way in which it opens and shuts the valves, yet as this is an essential part of the engine, we shall give a separate drawing of the mechanism which opens and shuts the nozzle valves and regulator, along with Mr. Watt's own description of it. "The piston approaching the top of the cylinder, the slider *a* fastened upon the plug tree *z*, raises up the handle *b*, which is fixed upon the lower Y shaft or axis *c*, as is the detent *d*, and the latter takes hold of the double ended catch *e*; but, in doing this, the upper end of the catch allows the detent *f* to escape, and a weight hung to the rod *g* turns the axis *h*. The arm *i* and rod *j* are moved out of the straight line at *l*, and by a lever *k* turn the spindle *m* in the upper nozzle, which, by means of a toothed sector *n*, and rack *o*, raises the valve *p*, and admits steam into the cylinder *above* the piston through the horizontal pipe A. At the same time, another arm *u*, fixed upon the same shaft, by means of the rod *w*, acts upon a spindle, &c. in the lower nozzle, and opens the exhaustion valve L (Plate DVII. Fig. 1.), and thereby forms a communication between the cylinder *below* the piston and the condenser. The piston now descending, another slider *q* moves the handle *r* into the position *s*; this raises the weight *g*, while *i* and *k* are brought back to the position *l*, and the valves *p* and L are shut. The detent *f*, in acting upon the catch *e*, disengages *d*; the lower Y shaft turns upon its axis, and two arms attached to it (similar to those upon the upper Y shaft, which are omitted to avoid confusion) by means of the rod *x* and *y*, open the lower steam valve K (Plate DVII. Fig. I.) and the upper exhaustion valve *t*. The cylinder above the piston becomes exhausted, and the steam, entering below it, causes the piston to re-ascend."

The steam engine of the form, which we have now described, continued long in use for draining mines. Between 1778 and 1790, great numbers of them were erected by Messrs. Bolton and Watt, in different parts of England, but chiefly in Cornwall. Their cylinders were generally from forty-eight to sixty-six inches in diameter, and according to Mr. Watt, they were found to raise from twenty-four to thirty-two millions of pounds of water one foot high by means of *one* bushel of good Newcastle or Swansea coals, when working more or less expansively.

As the action of these engines is suspended during the ascent of the piston, they were particularly suited for pumping up water, since during the intermission the piston of the pump descended to make a new stroke. But when a continued power was required for the purpose of driving machinery in which there was no intermission of action, this form of the steam-engine was by no means applicable.

Mr. Watt proposed to remedy this defect by placing a cylinder under each end of the great beam, in order that one of the pistons should be rising while the other was falling; and as both the cylinders were to be supplied from the same boiler, and the steam condensed in the same condenser, it was probable that these two actions on the beam would be regular and uniform.

This plan, however, was we believe never carried into effect, and Mr. Watt resolved upon using only one cylinder, and upon giving the engine a double action by introducing steam both above and below the piston, and thus forcing the piston both *upwards* and *downwards*. For this double engine he took out a patent in 1782, but as it was afterwards greatly improved, we shall describe one of those which existed at a later date for the Albion Mills. In his specification of 1782, the piston rod gave motion to the beam by a toothed rack, at the upper end of the rod, which wrought in a toothed arch, which replaced the arch head at the end of the beam, and the irregularities of this action were equalized by a fly-wheel placed near the top of the piston rod. This was, however, soon laid aside, and the contrivance adopted which is now in universal use. The following are the parts of this engine (See Plate DVIII. Fig. 1.):

A The cylinder 34 inches in diameter.
B The piston which makes a stroke eight feet long.
C The piston rod.
D The stuffing box or the cover of the cylinder.
E The steam-case or jacket of the cylinder.
  e The syphon which empties the steam-case of water.
  f The pipe which supplies the steam-case.
G The upper steam nozzle and valve, or regulator-box and regulator.
H The upper exhaustion nozzle and valves.
I The perpendicular steam pipe.
J The eduction pipe.
K The lower steam nozzle and valve.
L The lower exhaustion nozzle and valves.
M The condenser immersed in a cistern of cold water.
N The injection cock which is always open during the working of the engine.
O The blow valve.
P The air pump.
Q The lower valve and air pump.
R The bucket and rod of the air pump.
S The upper valve of the air pump.
T The hot water pump with its bucket and rod.
U The cold water pump.
V The pump for supplying the boiler.
W The governor turned by a belt from the shaft of the fly wheel.

X The lever and rod which connects the governor with the throttle valve at *t*.
Y The working gear of the nozzle valves.
Z The plug tree which drives the working gear.
a The main lever or working beam.
b Its main gudgeon.
c The perpendicular links of the parallel motion.
d The parallel bars.
e The regulating radiuses.
f The small perpendicular links.
g The secondary parallel motion for the air pump.
h The connecting rod.
i The planet-wheel fixed to the connecting rod.
j The iron wheel.
k The shaft of the fly-wheel on which the sun-wheel is fixed.
l The connecting link which retains the planet-wheel in its orbit.
m The fly-wheel.
n The boiler.
o The tube through the boiler and the flues around it.
p The grate.
q The feeding mouth.
r The damper.
s The chimney.
t The feed pipe.
u The guage pipes with their cocks.
v The safety valve.

The boiler *n*, in which the water is converted into steam by the furnace *p q*, is most frequently made of iron though sometimes of copper. Its bottom is concave, and the flame is made to circulate round its sides in the flue *o o*, and is sometimes conveyed through the very middle of the water by a tube *o*, in order that a great surface may be exposed to the action of the fire. In some of Mr. Watt's engines, the fire contained in a vessel of iron was introduced into the very middle of the water.

Before proceeding to describe the operation of Mr. Watt's double engine, we must first give an account of the construction of the regulating valves, and the manner in which the plug-tree acts upon their levers in opening and shutting them. A section of the regulator box is shown in Fig. 2. Plate DVIII, by the letters HHJJ. The opening into the cylinder is shown at HH. A spindle A passes through one side of the box, and upon this as an axis moves a toothed sector B, which works into the toothed rack C fixed to the brass valve D, fitted by grinding to its seat EE, F being the guide for the stem D *d* of the valve. On the spindle A is fixed a lever LA, jointed at L to the rod LM, which is again jointed at M to the arm MN of a bent lever MNO, movable round the axis N. Part of the plug-tree is shown at QR, and P is one of its pins. From this description it is obvious that the valve D will be opened or shut by the ascent or descent of the plug-tree QR, the pins of which act upon the lever NO. When the pin P pushes down the spanner NO, the arm MN rises to the right hand, and pulls down the spanner AL by means of the uniting rod ML; these parts are so arranged that when the cock is shut, LM and MN form one straight line as in the figure. Hence when the spanner begins to raise the valve, its mechanical energy is almost infinitely great, and from the same cause, if any thing should try to open the valve it would be ineffectual.

Operation of Mr. Watt's Double Engine.

By means of the steam pipe F, Plate DVIII. Fig. 1, the steam is conveyed from the boiler *n* to the cross pipe or upper steam nozle G, and by the perpendicular steam pipe I, to the lower steam nozle K. In the nozle G there is a valve (D. Fig. 2.) which, when open, admits steam into the cylinder above the piston B, through the horizontal square pipe at the top of the cylinder, and in the lower steam nozle K there is another valve like that at D, which, when opened by the pin of the plug-tree, admits steam into the cylinder below the piston. In the *upper* exhaustion nozle H there is a similar valve, which, when open, allows steam to pass from the cylinder *above* the piston into the eduction pipe J, which conveys it to the condensing vessel M, where it meets the jet of the injection from the cock N, and is reduced to water; and in the *lower* exhaustion nozle L there is also a valve, which, when open, allows the steam to pass out of the cylinder *below* the piston into the condenser M.

The engine, says Mr. Watt, being at rest, the cylinder quite cold, and the condenser cistern full of water, when the water in the boiler begins to boil, steam will enter by the small pipe *f* into the space between the cylinder and the heating-case E, which will expel the air contained in that space, and between the two bottoms of the cylinder, at a cock fixed in the outer bottom, which, when all the air is expelled, and the cylinder thoroughly warmed, is to be shut, and the water which may be formed in these spaces during the working of the engine, will issue by the inverted syphon *e*.

Things being in this situation to produce a commencement of motion, the first operation is to open all the four valves, G, H, K, L; (the injection cock being shut) the steam will drive the air out of the steam and exhaustion-pipes I and J, and out of the condenser M, through the blow-pipe and its valve O, and as soon as this is succeeded by a sharp crackling noise in the little cistern O, the valves are to be shut until it is thought that the steam which has entered is mostly condensed.

The same operation is to be repeated, giving a longer time to cool between the times of blowing, until it is found that, upon opening the injection-cock, some water will enter, and the barometer shall show some degree of exhaustion, after which, the repetition of blowing will soon empty the cylinder of air.

The piston being then at the top of its stroke, the valves G and L are to be opened, and the fly-wheel *m* turned by hand about one-eighth of a revolution, or more, in the direction in which it is intended to move; the steam which is then in the cylinder will pass by L into the condenser, when, meeting the jet of water from the injection-cock, it will be converted into water, and the cylinder thus becoming exhausted, the steam, entering the cylinder by the valve G, will press upon the piston and cause it to descend, while, by its action upon the working-beam through the piston-rod, &c., it pulls down the cylinder end of the beam, and raises up the outer end and the connecting rod *h*, which causes the planet-wheel *i* to tend to revolve round the sun-wheel *j*; but the former of these wheels, being fixed upon the connecting-rod so that it cannot turn upon its own axis, and its teeth being engaged in those of the sun-wheel, the latter, and the fly-wheel, upon whose axle or shaft it is fixed, are made to revolve in the desired direction, and give motion to the mill-work.

As the piston descends, the plug-tree Z also descends, and a clamp, or slider *q*, fixed upon the side of the plug-tree, presses upon the handle 1 of the upper Y-shaft, or axis, and thereby shuts the valves G and L, and the same operation, by disengaging a detent, permits a weight suspended to the arm of the lower Y-shaft to turn the shaft upon its axis, and thereby to open the valves K and H. The moment previous to the opening of these valves, the piston had reached the lowest part of its stroke, and the cylinder *above* the piston was filled with steam; but as soon as H is opened, that steam rushes by the eduction-pipe J, into the condenser, and the cylinder *above* the piston becomes exhausted. The steam from the boiler entering by I and K, acts upon the *lower* side of the piston, and forces it to return to the top of the cylinder. When the piston is very near the upper termination of its stroke, another slider *a* raises the handle 2, and, in so doing, disengages the catch which permits the upper Y-shaft to revolve upon its own axis, and open the valves G and L, and the downward stroke recommences as has been related.

When the piston descends, the buckets R, T of the air-pump P and hot water pump T also descend. The water which is contained in these pumps passes through the valves of their buckets, and is drawn up and discharged by them through the lander or trough *t*, by the next descending stroke of the piston. Part of this water is raised up by the pump V, for the supply of the boiler, and the rest runs to waste."

The engine now described was one of fifty horse power, and was erected along with another of the same power, to drive twenty pair of mill stones, of which twelve or more pairs, with all the machinery for dressing the flour and other purposes, were generally kept at work.

Although Mr. Watt's double engines were chiefly employed in producing rotatory motions, yet in the case of very deep mines they may be applied with very great advantage to work pumps, by a reciprocating motion.

For this purpose one set, or half of the pump rods, are suspended by means of a sloping rod from the working beam near the cylinder, and the other half of these rods are suspended directly from the outer end of that beam, so that the ascending motion of the piston pulls up one half of these rods, and works the pumps to which they belong, while the descending motion of the piston pulls up the other half of the rods and works their pumps.

A double engine of this kind was erected at Wheel Maid Mine in Cornwall in 1787. It had a cylinder of sixty-three inches diameter, and nine feet stroke; but the stroke in the pumps, which were eighteen inches in diameter, was only seven feet. When it was inconvenient to divide the pump rods into two sets, the ascending motion of the piston was employed to raise a weight equal to one half the column of water in the pumps, and this weight acted in addition to the power of the engine during the descending stroke of the piston.

Such is a general description of the new engine as improved by Mr. Watt, but some of its individual parts still remain to be noticed.

The first of these contrivances is the *Sun and Planet Wheel*, which is shown in Fig. 1, Plate DVIII, where the wheel *j* is called the *Sun* Wheel, and *i* the *Planet* Wheel. The sun wheel *j* is fixed in a horizontal axis, to which it is required to communicate a continuous rotatory motion by the reciprocating motion of the rod *h*, suspended from one extremity of the great beam. The planet wheel *i* is fixed to the lower end of the rod *h*, so that it cannot turn round its axis. The sun and planet wheels are of the same size, move in the same vertical plane, and have the same number of teeth; and their centres are connected together by an iron strap, which prevents them from quitting each other. If we suppose the rod *h* to rise with the end of the beam which carries it, the teeth on the inner or left hand side of the planet wheel *i* will obviously work in the teeth of the inner or left hand side of the sun wheel *j*. When the centre of the planet wheel comes on a level with the centre of the sun wheel, it will then have performed one-fourth of a revolution, so that the two wheels will have made one quarter of a revolution in respect to one another; but the planet wheel will also have made one-fourth of a revolution in its orbit round the sun wheel, and have carried the sun wheel along with it, so that the latter will have completed *half* a revolution. In like manner when the centre of the planet wheel is above the centre of the sun wheel, the former will have completed half a revolution, and the latter a whole revolution. This double velocity of the sun wheel arises from the motion of the planet wheel around it. If the planet wheel were twice the size of the sun wheel, the latter would perform three revolutions for one of the former. See Mechanics, Vol. XII., p. 660.

The following is the history of this beautiful contrivance as given by Mr. Watt himself:

"Having made my reciprocating engines very regular in their movements, I considered how to produce rotative motions from them in the best manner; and amongst various schemes which were subjected to trial, or which passed through my mind, none appeared so likely to answer the purpose as the application of the crank in the manner of the common turning lathe, (an invention of great merit, of which the humble inventor, and even its æra, are unknown). But, as the rotative motion is produced in that machine by the impulse given to the crank in the descent of the foot only, and behoves to be continued in its ascent by the momentum of the wheel which acts as a fly, and being unwilling to load my engine with a fly heavy enough to continue the motion during the ascent of the piston, (and even were a counter-weight employed to act during that ascent, of a fly heavy enough to equalize the motion), I proposed to employ two engines acting upon two cranks fixed on the same axis at an angle of 120 degrees to one another, and a weight placed upon the circumference of the fly at the same angle to each of the cranks, by which means the motion might be rendered nearly equal, and a very light fly would only be requisite. This had occurred to me very early, but my attention being fully employed in making and erecting engines for raising water, it remained in petto until about the year 1778 or 9, when Mr. Wasbrough erected one of his ratchet-wheel engines at Birmingham, the frequent breakages and irregularities of which recalled the subject to my mind, and I proceeded to make a model of my method, which answered my expectations; but having neglected to take out a patent, the invention was communicated by a workman employed to make the model to some of the people about Mr. Wasbrough's engine, and a patent was taken out by them for the application of the crank to steam-engines. This fact the said workman confessed, and the engineer who directed the works acknowledged it, but said, nevertheless, the same idea had occurred to him prior to his hearing of mine, and that he had even made a model of it before that time, which might be a fact, as the application to a single crank was sufficiently obvious. In these circumstances I thought it better to endeavour to accomplish the same end by other means, than to enter into litigation, and, if successful, by demolishing the patent, to lay the matter open to every body. Accordingly, in 1781, I invented and took out a patent for several methods of producing rotative motions from reciprocating ones, amongst which was the method of the sun and planet wheels.

"This contrivance was applied to many engines, and possesses the great advantage of giving a double velocity to the fly; but is perhaps more subject to wear, and to be broken under great strains, than the crank, which is now more commonly used, although it requires a fly-wheel of four times the weight, if fixed upon the first axis. My application of the double engine to these rotative machines rendered unnecessary the counter-weight, and produced a more regular motion; so that, in most of our great manufactories, these engines now supply the place of water, wind, and horse mills; and instead of carrying the work to the power, the prime agent is placed wherever it is most convenient to the manufacturer."

But whether the rotatory motion is produced by the simple crank,* or by the sun and planet wheel, there is an irregularity in its action, which it is necessary to correct. The force of the planet wheel to drive the sun wheel is constantly varying. In the position shown in Fig. 1, Plate DVIII, and also in the position when the planet wheel is exactly above the sun wheel, it is nothing. It then gradually increases till the centres of the two wheels are in the same horizontal line, and from that point it again diminishes. In the two positions when the force is nothing, we might expect that the engine would stop, as the action of the steam tends only to press the axis of the planet wheel against that of the sun wheel. But as the planet wheel, when once put in motion, has a tendency to go on, it never can stop at these two positions of minimum force, and the instant it passes them it acquires fresh power to continue its motion. It is obvious, however, that such a motion must be irregular, being slow in one position and quick in another.

In order to remedy this evil, a large and heavy *fly-wheel m* is fixed on the axis of the sun wheel *j*. This heavy wheel, when once put in motion, equalises the irregular motion of the planet wheel in the manner which we have already fully explained in our article MECHANICS, (Vol. XII. p. 666.)

The other contrivances invented by Mr. Watt we shall describe in his own words.

"The Parallel Motion, in the single engines, serves in place of chains, and in the double engines, supplies the place of the rack and sector. It has been mentioned, that the racks and sectors were very subject to wear, and that, when perfect, they did not move with that smoothness that was wished; and to chains there were many objections. It occurred to Mr. Watt, that if some mechanism could be devised moving upon centres, which would keep the piston-rods perpendicular, both in pushing and pulling, a smoother motion would be attained; and, in all probability, that the parts would be less subject to wear. After some consideration, it occurred to him, that if two levers of equal lengths were placed in the same vertical plane, nearly, as shown in Fig. 3 of plate DVIII, moveable on the centres B and C, and connected by a rod A D, the point E, in the middle of that rod, would describe nearly a straight and perpendicular line, when the ends A and D of the levers, and of that rod, moved in the segments of circles FG, and IH, provided the arch FG did not much exceed 40 degrees, and consequently that if the top of the piston-rod were attached to that point E, it would be guided perpendicularly, or nearly so.

It necessarily followed, that if for convenience the lever CD (which represents what he called the regulating-radius) were made only half the length of the lever AB (which represents the half length or radius of the working-beam) a point situated at one-third of the length of the rod AD, from the joint A, would then move in a perpendicular line. These were first ideas, but the parallel motion was soon moulded into the form in which it appears in all Boulton and Watt's engines, and in which it is seen in Plate DVIII, Fig. 1, of the second engine at the Albion Mill. A patent for the protection of this, and some other of Mr. Watt's invention, passed the seals in April 1784, but the invention was made in the latter end of 1783.

The regulation of the speed of the rotative engines, is a matter essential to their application to cotton spinning, and many other manufactories.

It is performed by admitting the steam into the cylinder more or less freely, by means of what is called a *Throttle-valve*, which is commonly a circular plate of metal A, Fig. 4, having a spindle B fixed across its diameter.

This plate is accurately fitted to an aperture in a metal ring CC, of some thickness, through the edgeway of which the spindle is fitted steam-tight, and the ring is fixed between the two flanches of the joint of the steam-pipe which is next to the cylinder. One end of the spindle, which has a square upon it, comes through the ring, and has a spanner fixed upon it by which it can be turned in either direction.

When the valve is parallel to the outsides of the ring, it shuts the opening nearly perfectly; but when its plane lies at an angle to the ring, it admits more or less steam according to the degree it has opened; consequently the piston is acted upon with more or less force. For many purposes engines are thus regulated by hand at the pleasure of the attendant; but where a regular velocity is required, other means must be applied to open and shut it, without any attention on the part of those who have the care of it. For this purpose Mr. Watt had various methods, but at last fixed upon what he calls the *Governor*, (shown at W. Plate DVIII, Fig. 1.) consisting of a perpen-

* See MECHANICS, Vol. XII.—p. 661.

dicular axis, turned by the engine: To a joint near the top of this axis are suspended two iron rods, carrying heavy balls of metal at their lower ends, of the nature of pendulums. When this axis is put in motion by the engine, the balls recede from the perpendicular by the centrifugal force, and by means of a combination of levers fixed to their upper end, raise the end of a lever which acts upon the spanner of the throttle-valve, and shuts it more or less according to the speed of the engine, so that as the velocity augments, the valve is shut, until the speed of the engine and the opening of the valve come to a maximum and balance each other.

The application of the centrifugal *principle* was not a new invention, but had been applied by others to the regulation of water and wind-mills, and other things; but Mr. Watt improved the mechanism by which it acted upon the machines, and adapted it to his engines.

From the beginning, Mr. Watt applied a gage to show the height of the water in his little boiler, which consisted of a glass tube communicating at the lower end with the water in the boiler, and at the upper end with the steam contained in it. This gage was of great use in his experiments, but in practice other methods are adopted. He has always used a barometer to indicate the degree of exhaustion in his engines. Sometimes that instrument is, as usual, a glass tube 33 or 34 inches long, immersed at bottom in a cistern of mercury, and at top communicating by means of a small pipe and cock with the condenser. The oscillations are in a great degree prevented by throttleing the passage for the steam by means of the cock.

But as glass tubes were liable to be broken by the workmen, barometers were made of iron tubes, in the form of inverted syphons, one leg being about half the length of the other. To the upper end of the long leg a pipe and cock were joined, which communicated with the condenser; a proper quantity of mercury was poured into the short leg of the syphon, which naturally stood level in the two legs: A light float with a slender stem was placed in the short leg, and a scale divided into half inches applied to it, which (as by the exhaustion the mercury rose as much in the long leg as it fell in the short one) represented inches on the common barometer.

The steam-gage is a short glass tube with its lower end immersed in a cistern of mercury, which is placed within an iron box screwed to the boiler steam-pipe, or to some other part communicating freely with the steam, which, pressing on the surface of the mercury in the cistern, raises the mercury in the tube, (which is open to the air at the upper end) and its altitude serves to show the elastic power of the steam over that of the atmosphere.

These instruments are of great use where they are kept in order, in showing the superintendant the state of the engine; but slovenly engine-tenders are but too apt to put them out of order, or to suffer them to be so. *It is the interest, however, of every owner of an engine to see that they, as well as all other parts of the engine, are kept in order.*

The barometer being adapted only to ascertain the degree of exhaustion in the condenser where its variations were small, the vibrations of the mercury rendered it very difficult, if not impracticable, to ascertain the state of the exhaustion of the cylinder at the different periods of the stroke of the engine; it became therefore necessary to contrive an instrument for that purpose, that should be less subject to vibration, and should show nearly the degree of exhaustion in the cylinder at all periods. The following instrument, called the *Indicator*, is found to answer the end sufficiently. A cylinder about an inch diameter, and six inches long, exceedingly truly bored, has a solid piston accurately fitted to it, so as to slide easy by the help of some oil; the stem of the piston is guided in the direction of the axis of the cylinder, so that it may not be subject to jam or cause friction in any part of its motion. The bottom of the cylinder has a cock and small pipe joined to it, which, having a conical end, may be inserted in a hole drilled in the cylinder of the engine near one of the ends, so that by opening the small cock, a communication may be effected between the inside of the cylinder and the indicator.

The cylinder of the indicator is fastened upon a wooden or metal frame, more than twice its own length; one end of a spiral steel spring, like that of a spring steelyard, is attached to the upper end of the piston-rod of the indicator. The spring is made of such a strength, that when the cylinder of the indicator is perfectly exhausted, the pressure of the atmosphere may force its piston down within an inch of its bottom. An index being fixed to the top of its piston-rod, the point where it stands, when quite exhausted, is marked from an observation of a barometer communicating with the same exhausted vessel, and the scale divided accordingly.

Mr. Watt very early found that, although most kinds of grease would answer when employed to keep the piston tight, yet that beef or mutton tallow were the most proper, and the least liable to decompose; but when cylinders were new and imperfectly bored, the grease soon disappeared, and the piston was left dry; he therefore endeavored to detain it by thickening it with some substance which would lubricate the cylinder, and not prove decomposable by heat and exhaustion. Black-lead dust seemed a proper substance, and was therefore employed, especially when a cylinder or the packing of a piston was new; but it was found in the sequel that the black-lead wore the cylinder, though slowly; and by more perfect workmanship, cylinders are made so true as not to require it, or at least, only for a very short time at first using.

The joints of the cylinder, and other parts of Newcomen's engines, were generally made tight by being screwed together upon rings of lead covered with glazier's putty, which method was sufficient, as the entry of small quantities of air did not materially affect the working of these engines where only a very imperfect exhaustion was required. But the contrary being the case in the improved engines, this method would not answer Mr. Watt's purpose. He at first made his joints very true, and screwed them together upon pasteboard, softened by soaking them in water, which answered tolerably well for a time, but was not sufficiently durable. He therefore endeavoured to find out some more lasting substance; and observing that at the iron founderies they filled up flaws by iron borings or filings, moistened by urine, which in time became hard, he improved upon this by mixing the iron borings or filings with a small quantity of sulphur, and a little sal-ammoniac, to which he afterwards added some fine sand from the grindstone troughs. This mixture, being moistened with water and spread upon the joint, heats soon after it is screwed together, becomes hard, and remains good and tight for years, which has contributed in no small degree to the perfection of the engines.

Mr. Murdock, much about the same time, without communication with Mr. Watt, made a cement of iron borings and sal-ammoniac, without the sulphur. But the latter gives the valuable property of making the cement set immediately.

The following is an account of the actual performance of some of Mr. Watt's engines, as given by himself:

The burning of one bushel of good Newcastle or Swansea coals in Mr. Watt's reciprocating engines, working more or less expansively, was found, by the accounts kept at the Cornish mines, to raise from 24 to 32 millions of pounds of water one foot high: the greater or less effect depending upon the state of the engine, its size, and rate of working, and upon the quality of the coal.

In engines upon the rotative double construction, one having a cylinder of 31½ inches diameter, and making 17½ strokes of 7 feet long per minute, called 40 horses' power,* meaning the constant exertion of 40 horses (for which purpose, supposing the work to go on night and day, 3 relays, or at least 120 horses, must be kept) consumed about 4 bushels of good Newcastle coal per hour, or 400 weight of good Wednesbury coal. A rotative double engine, with a cylinder of 23¾ inches in diameter, making 21½ strokes of 5 feet long per minute, was called 20 horses' power; and an engine, with a cylinder of 17½ inches diameter, making 25 strokes of 4 feet long per minute, was called 10 horses' power; and the consumption of coals by these was nearly proportional to that of the 40 horses' power.

A bushel of Newcastle coals, which thus appears to be the consumption of a 10 horse engine for one hour, grinds and dresses about 10 bushels, Winchester measure, of wheat.

The quantity of water necessary for injection may be determined on principle for engines having a separate condenser. Having found the contents of the cylinder in cubic feet (that is, the area of the piston multiplied by the length of the stroke + $\frac{1}{10}$ to allow for the vacuities at top and bottom through which the piston does not pass,) it is to be considered that every cubic foot of steam produces about a cubic inch of water when condensed, and contains about as much latent heat as would raise 960 cubic inches of water one degree. This steam must not only be condensed, but must be cooled down to the temperature of the hot well: therefore as many inches of cold water must be employed as will require all this heat to raise it to the temperature of the hot well.

Therefore let c be the quantity of steam to be condensed in cubic feet;

a = the temperature of the cold water (per Fahrenheit);

b = the proposed temperature of the warm water, or hot well;

1172 = the sensible and latent heat of steam;

x = the cubic inches of cold water required to condense c.

Then $c \times \overline{1172-b} = x + \overline{b+a}$:

Therefore $c \times \frac{1172-b}{b-a} = x$.

Thus, if the proposed temperature of the hot well be 100° (and it should not be higher to obtain a tolerable vacuum in the cylinder), and that of the injection be 50°, we have $a = 50°$, $b = 100°$; hence $\frac{1172-100}{100-50} = 21.44 = x$. That is, for every foot of the capacity of the stroke in the cylinder $+\frac{1}{10}$, calculated as has been directed, or for every cubic inch of water evaporated from the boiler, about 21½ cubic inches of water at 50° will be required to condense the steam.

But as the injection water may not be obtained so cold as 50°, and other circumstances may require an allowance, a wine pint of water for every inch boiled off, or for every cubic foot of the contents of the stroke in the cylinder, may be kept in mind as amply sufficient. This greatly exceeds the quantity necessary in a good Newcomen's engine, and by showing the more perfect condensation, points out the superiority of the new engine; for the Newcomen's engine, if working to the greatest advantage, should not be loaded to more than 7 pounds upon the inch, whereas Watt's engine bears a load not much less than 11 pounds, exclusive of friction, when making twelve 8-feet strokes per minute.

What has been now said is not a matter of mere curiosity: it affords an exact rule for judging of the good working order of the engine. We can measure with accuracy the water admitted into the boiler during an hour without allowing its surface to rise or fall, and also the water employed for injection. If the last be above the proportion now given (adapted to the temperatures 50° and 100°), we are certain that steam is wasted by leaks, or by condensation in some improper place.

It is evident that it is of great importance to have the temperature of the hot well as low as possible, because there always remains steam in the cylinder of the same or rather higher temperature, possessing an elasticity which balances part of the pressure on the other side of the piston, and thus diminishes the power of the engine. This is clearly seen by the barometer which Mr. Watt applies to his engines, and is a most useful addition to the proprietor. It shows him the

* "When Boulton and Watt set about the introduction of the rotative steam-engines, to give motion to mill-work, they felt the necessity of adopting some mode of describing the power, which should be easily understood by the persons who were likely to use them. Horses being the power then generally employed to move the machinery in the great breweries and distilleries of the metropolis, where these engines came first into demand, the power of a mill-horse was considered by them to afford an obvious and concise standard of comparison, and one sufficiently definite for the purpose in view.

"A horse going at the rate of 2½ miles an hour raises a weight of 150 lbs. by a rope passing over a pulley, which is equal to the raising 33,000 lbs. one foot high in a minute. This was considered the horse's power; but in calculating the size of the engines, it was judged advisable to make a very ample allowance for the probable case of their not being kept in the best order, and therefore the load was only assumed at about 7 lbs. on the square inch of the piston, although the engines work well to 10 lbs. on the inch, exclusive of their own friction." W.

state of the vacuum, and, with the height of the mercury in the steam-guage, points out the real power of the engine.

Mr. Watt finds that, with the most judiciously constructed furnaces, it requires 8 feet of surface of the boiler to be exposed to the action of the fire and flame to boil off a cubic foot of water in an hour, and that a bushel of Newcastle coals so applied will boil off from 8 to 12 cubic feet, and that it requires about a cwt. of Wednesbury coals to do the same.

Having thus given a general view of the inventions of Mr. Watt, we shall proceed to give an account of the labours of his contemporaries and his successors. The variations, however, which the steam engine has undergone are so numerous, that it would be impossible in a work like this, intended for general readers, to embrace all those contrivances which have been published; so that we must confine ourselves to those which have been regarded as combining ingenuity with practical utility.

Description of Mr. Hornblower's Engine with two Cylinders.

As this engine is now in more extensive use than any other variety excepting Mr. Watts, and notwithstanding its similarity in principle to Mr. Watts, displays much ingenuity, it is necessary to give a full description of it. Hornblower does not seem to have published any account of his own engine, excepting the one which he sent to Dr. Robison, so that we have no alternative but to lay this before our readers.

Mr. Hornblower had erected his engine for different manufactories, and for winding up coal at collieries, and in 1796 he erected one at Messrs. Meux's brewery in London. Messrs. Boulton and Watt raised an action against Messrs. Hornblower and Maberly for an infringement of the patent, and a decision was given in the Court of Common Pleas in favour of Mr. Watt.

The principal parts of Mr. Hornblower's engine are two cylinders, A, B, Plate DIX, Fig. 1, the largest of which is A. A piston moves in each, having their rods C and D moving through collars at E and F. These cylinders may be supplied with steam from the boiler by means of the square pipe G, which has a flanch to connect it with the rest of the steam-pipe. This square part is represented as branching off to both cylinders. *c* and *d* are two cocks, which have handles and tumblers as usual, worked by the plug-beam W. On the fore-side (that is the side next the eye) of the cylinders is represented another communicating pipe, whose section is also square or rectangular, having also two cocks *a*, *b*. The pipe Y, immediately under the cock *b*, establishes a communication between the upper and lower parts of the small cylinder B, by opening the cock *b*. There is a similar pipe on the other side of the cylinder A, immediately under the cock *d*. When the cocks *c* and *a* are open, and the cocks *b* and *d* are shut, the steam from the boiler has free admission into the upper part of the cylinder B, and the steam from the lower part of B has free admission into the upper part of A; but the upper part of each cylinder has no communication with its lower part.

From the bottom of the great cylinder proceeds the eduction-pipe K, having a valve at its opening into the cylinder, which bends downwards, and is connected with the conical condenser L. The condenser is fixed on a hollow box M, on which stand the pumps N and O for extracting the air and water; which last runs along the trough T into a cistern U, from which it is raised by the pump V for recruiting the boiler, being already nearly boiling hot. Immediately under the condenser there is a spigot valve at S, over which is a small jet pipe, reaching to the bend of the eduction-pipe. The whole of the condensing apparatus is contained in a cistern R of cold water. A small pipe P comes from the side of the condenser, and terminates on the bottom of the trough T, and is there covered with a valve Q, which is kept tight by the water that is always running over it. Lastly, the pump-rods X cause the outer end of the beam to preponderate, so that the quiescent position of the beam is that represented in the figure, the pistons being at the top of the cylinders.

Suppose all the cocks open, and steam coming in copiously from the boiler, and no condensation going on in L; the steam must drive out all the air, and at last follow it through the valve Q. Now shut the valves *b* and *d*, and open the valve S of the condenser. The condensation will immediately commence. There is now no pressure on the under side of the piston of A, and it immediately descends. The communication between the lower part of B and the upper part of A being open, the steam will go from B into the space left by the piston of A. It must therefore expand, and its elasticity must diminish, and will no longer balance the pressure of the steam above the piston of B. This piston, therefore, if not withheld by the beam, would descend till it is in equilibrio, having steam of equal density above and below it. But it cannot descend so far; for the cylinder A is wider than B, and the arm of the beam at which its piston hangs is longer than the arm which supports the piston of B: therefore when the piston of B has descended as far as the beam will permit it, the steam between the two pistons occupies a larger space than it did when both pistons were at the tops of their cylinders. Its density, therefore, and its elasticity, diminish as its bulk increases. It is therefore not a balance; for the steam on the upper side of B, and the piston B, *pulls* at the beam with all the difference of these pressures. The slightest view of the subject must show the reader, that as the pistons descend, the steam that is between them will grow continually rarer and less elastic, and that both pistons will pull the beam downwards.

Suppose now that each has reached the bottom of its cylinder. Shut the cock *a* and the eduction cock at the bottom of A, and open the cocks *b* and *d*. The communication being now established between the upper and lower part of each cylinder, nothing hinders the counter weight from raising the pistons to the top. Let them arrive there. The cylinder B is at this time filled with steam of the ordinary density, and the cylinder A with an equal absolute quantity of steam, but expanded into a larger space.

Shut the cocks *b* and *d*, and open the cock *a*, and the eduction cock at the bottom of A; the condensation will again operate, and the pistons descend. And thus the operation may be repeated as long as steam is supplied; and one full of the cylinder B of ordinary steam is expended during each working stroke.

Let us now examine the power of this engine. It is evident, that when both pistons are at the top of their respective cylinders, the active pressure (that is, the difference of the pressure on its two sides) on the piston of B is nothing, while that on the piston of A is equal to the full pressure of the atmosphere on its area. This, multiplied by the length of the arm by which it is supported, gives its mechanical energy. As the pistons descend, the pressure on the piston of B increases, while that on the piston of A diminishes. When both are at the bottom, the pressure on the piston of B is at its maximum, and that on the piston of A at its minimum.

Mr. Hornblower saw that this must be a beneficial employment of steam, and preferable to the practice of condensing it while its full elasticity remained; but he has not considered it with the attention necessary for ascertaining the advantage with precision.

Dr. Robison then proceeds to an investigation of the effect of this engine, and he finds it to be exactly the same with the accumulated pressure of a quantity of steam admitted in the beginning, and stopped in Mr. Watt's method, when the piston has descended through the *m*th part of the cylinder. In considering, says he, Mr. Hornblower's engine, the thing was presented in so different a form that we did not perceive the analogy at first, and we were surprised at the result. We could not help even regretting it, because it had the appearance of a new principle and an improvement; and we doubt not but that it appeared so to the ingenious author; for we have had such proof of his liberality of mind as permit us not to suppose that he saw it from the beginning, and availed himself of the difficulty of tracing the analogy. And as the thing may mislead others in the same way, we have done a service to the public by showing that this engine, so costly and so difficult in its construction, is no way superior in power to Mr. Watt's simple method of stopping the steam. It is even inferior, because there must be a condensation in the communicating passages. We may add, that if the condensation is performed in the cylinder A, which it must be unless with the permission of Watt and Boulton, the engine cannot be much superior to a common engine; for much of the steam from below B will be condensed between the pistons by the coldness of the cylinder A; and this diminishes the downward pressure on A more than it increases the downward pressure on B. The disposition and connection of the cylinders, and the whole condensing apparatus, are contrived with peculiar neatness. The cocks are very ingenious; they are composed of two flat circular plates ground very true to each other, and one of them turns round on a pin through their centres; each is pierced with three sectoral apertures, exactly corresponding with each other, and occupying a little less than one half of their surfaces. By turning the moveable plate so that the apertures coincide, a large passage is opened for the steam; and by turning it so that the solid of the one covers the aperture of the other, the cock is shut. Such regulators are now very common in the cast iron stoves for warming rooms.

Mr. Hornblower's contrivance for making the collars for the piston rods air tight is also uncommonly ingenious. This collar is in fact two, at a small distance from each other. A small pipe, branching off from the main steam pipe, communicates with the space between the collars. This steam, being a little stronger than the pressure of the atmosphere, effectually hinders the air from penetrating by the upper collar; and though a little steam should get through the lower collar into the cylinder A, it can do no harm. We see many cases in which this pretty contrivance may be of signal service.

But it is in the framing of the great working beam that Mr. Hornblower's scientific knowledge is most conspicuous; and we have no hesitation in affirming that it is stronger than a beam of the common form, and containing twenty times its quantity of timber. There is hardly a part of it exposed to a transverse strain, if we except the strain of the pump V on the strutt by which it is worked. Every piece is either pushed or pulled in the direction of its length. We only fear that the bolts which connect the upper beam with the two iron bars under its ends will work loose in their holes, and tear out the wood which lies between them. We would propose to substitute an iron bar for the whole of this upper beam. This working beam highly deserves the attention of all carpenters and engineers."

Before concluding this account of Mr. Hornblower's engine, we shall describe a very ingenious skeleton valve of his invention, which has been found of great advantage. It is shown in Plate DIX. Fig. 2, 3, where AAAA is the box containing the valves, BB is an inverted valve firmly fixed to the bottom of the socket S; this socket serves as a guide to the part of the valve which is to be lifted by a short cylindrical rod as in common cases. The part which is to be lifted is DDEE, and the lifting is to be performed by any of the usual methods attached to the eye F, which is part of the cross bar EE in Fig. 3, which is a plan of the upper surface of the valve and its upper seat. The valve has two seats, and the principal passage for the steam is at the lower seat, for the steam in its passage goes through the body of the valves, having always access to the lower seating, as the body of the valve is entirely open, excepting what is taken up by the cross bar EE; so that in this sense we lift the thickness of the metal only, of which the body of the valve is constructed. In order to understand the operation of the valve better, we must conceive the upper space in the box to be always full of steam, and consequently the inner part OO of the valve also full; then the lower space of the box will be a vacuum, when upon lifting the valve (which is a cylinder open at both ends) the steam will pass through it and into the lower space at the inverted lid BB. The cylindrical part is raised a little in the figure to show how it separates from the lower lid BB. An improvement in this valve has been suggested by Mr. Tredgold. The practical difficulty being to make it fit steam tight on two seats, he proposes to make the outside of the cylinder to slide in a stuffing box, or in an elastic packing of metal. When this is done, the largest valves will present no other resistance to being opened than the pressure on the seat, and the friction of the surface of the cylinder. "It is simply," says Mr. Tredgold, "the common conical valve inverted, and that which formed the seat in the common valve moves instead of the plate, and should obviously slide in a steam-tight case."

Account of Trevithick's High Pressure Engine.

We have already described the high pressure engine invented by Leupold. Without knowing what had been done by Leupold, Mr. Watt conceived the same idea, but his views were never put in practice, and it was reserved to Mr. Trevithick of Camborne in Cornwall, to bring the high pressure engine into general use. In conjunction with Mr. Vivian of the same place, he took out a patent in 1802, for a high pressure engine. His principal object was to form an engine so compact and portable that it could be applied to the moving of carriages on rail roads. This great object he completely attained, and it was first applied as the moving power of carriages on a railway at Merthyr Tydvil in 1805. Since that time it has been employed in various collieries near Leeds, Wigan, and Newcastle upon Tyne.

This engine is represented in Plate DIX. Fig. 4., where AA is a cylindrical boiler of cast iron from three to four feet in diameter, and from nine to twelve feet long. The fire is made in a double wrought iron tube of the form of a syphon (one of the legs is shown at D) lying horizontally within the large cylinder AA. The two ends of the double tube are attached to the plate *d*. One of the ends is occupied with the fire door and ash pit, and the bars on which the fire is made, while its other end contracts into the iron chimney or flue T, having a door Z below for removing the soot. The boiler is filled with water above the surface of the double tube D, as shown in the figure. The steam cylinder A is almost wholly inclosed within the boiler, so as to be kept at the same heat as the water. The piston rod H attached to the piston G is fixed to the middle of a cross bar I at right angles to the length of the boiler. At the extremity of the cross bar are two connecting rods L, the lower ends of which are jointed to two cranks which drive the axis of the fly-wheel M. When a vertical reciprocating motion is required, it is attained at once from the cross bar I. The *fourway cock* for admitting the steam into the cylinder, and already represented in Leupold's engine, is shown at *i*, *f*, *g*, *k*. The steam from the boiler passes directly through the passage *g*, and brings steam to the cock, so that it can be admitted either above or below the piston, according to the position of the cock, *f* being the passage that carries it above the piston, and *k* that which carries it below the piston. The fourth passage *i* allows the steam to fly off into the flue T after it has exerted its expansive force upon the piston. The method of opening and shutting the cocks is similar to that used in other engines. The safety valve *n* is kept down by a lever *p v* with a weight *p*. The cold water is carried to the boiler by a pipe *r* enclosing the waste-pipe IF which is kept hot by the discharged steam, and which, therefore, gives out its heat to the cold water.

In the engines which Mr. Trevithick erected in Cornwall, he introduced the cylindrical tube boiler which is now generally used in that part of England. It is shown in Plate DIX. Fig. 5, where *aa* represents the part containing the water. The fire place is at the end of the tube A, and the heated air, after passing through A, returns through the flue B, which passes horizontally beneath the boiler to the end at which the fire is situated. Here it divides into two branches which pass along *c c*, into the flues DD, by which it is conveyed along the sides of the boiler, and thence escapes to the chimney.*

Woolf's Engine.

The engines introduced by Mr. Woolf were founded on an erroneous law of expansion, which, having been given by so respectable an engineer as the direct result of experiment, misled many writers into the belief of its correctness. But though the law which he assumed was erroneous, yet the engines which he introduced had considerable merit. They were nothing more indeed, than the application of high pressure steam to the double cylinder engine of Hornblower, in which Mr. Watt's condensing apparatus was employed in consequence of the expiry of his patent.

When Mr. Woolf went into Cornwall he erected some engines of this kind, and by having them made and fitted together with much more accuracy than had hitherto been the practice in that neighbourhood, he obtained from them a much better performance than had yet been obtained from Mr. Watt's engines. One of these at Huel Abraham mine was found, during a trial of twenty-four hours, to lift *seventy million of pounds* one foot high by the combustion of one bushel of coal (Mr. Henwood in Dr. Brewster's *Journal*, No. xix, p. 36.) Their effect was very far beyond that of any of Mr. Watt's engines which were then at work in the neighbourhood, as appears from a statement of their performance which was published periodically; but this arose not from any superiority in the principle of Woolf's engine, but solely from the great attention which he paid to the joints, and the fitting together of the parts.

In 1820 when Mr. Woolf was appointed engineer of the consolidated mines, he was anxious to erect some double cylinder engines; but this proposal met with opposition, and some very large engines of Watt's construction were made. Every attention was paid to proportion and workmanship, and from a performance of twenty and twenty-five millions of pounds lifted one foot by the combustion of a bushel of coal, they rose to forty and even forty-eight millions. The sufficiency of Mr. Watt's engines was now placed beyond a doubt, and only one of Mr. Woolf's has been since erected. Mr. Woolf, however, has great merit in having introduced that accuracy of workmanship and niceness of fitting by which Mr. Watt's engines obtained their superiority.

Mr. Woolf made some improvements on the boilers of steam engines which merit notice. His boilers consisted of a horizontal cylinder or reservoir for containing steam and water, having a series of horizontal tubes below it crossing it at right angles, and connected by short necks with the reservoir. Between these tubes, and over and above them alternately, the flame and heated air traversed in its passage to the chimney. He proposed another ingenious plan of having an upper and a lower boiler connected by short tubes; but though this exposes much surface, it is troublesome to execute; but, as Mr. Henwood † remarks, being usually made of cast iron, and continually

* Dr. Brewster's *Journal of Science*, No. XVII. p. 159.

† Dr. Brewster's *Journal of Science*, No. XIX, p. 36.

exposed to the intense action of the fire, the water was frequently driven out of them, and their temperature became considerably elevated; by the readmission of water at a comparatively low temperature, they were rapidly cooled, and the consequent contraction occasioned frequent fracture, not only of the joints, but also of the tubes themselves. Frequent trials demonstrated their inferiority to those of Trevithick, in favour of which they were soon relinquished.

Account of Mr. Grose's Improvements on the Steam Engine.

About the end of the year 1826, Mr. Grose was called upon to superintend the manufacture of some steam engines at Huel Towan, and the average duty (performance) of the one which was first worked was nearly 50 millions of pounds. Mr. Grose now applied a coating of saw dust about ten inches thick to the steam-pipes, nozle, cylinder, &c., and a stratum of ashes of nearly the same depth to the top of the boiler. By this means the duty was raised to about 65 millions. As there was still, however, a considerable loss of heat, another coating of the same material of the same thickness was applied on the outside of the first coating, and the result of this was an increase of the duty to *eighty-seven* millions, which was the average of a trial made in the presence of Mr. Henwood and several engineers and scientific individuals. Pursuing Mr. Grose's idea, Mr. Woolf has brought one of his engines to a duty of nearly 70 millions, as already mentioned.

The gradual improvement which has taken place in the steam-engines in Cornwall, may be seen from the following table drawn up by Mr. Henwood.

	No. of Engines in Cornwall.	Average duty in millions of pounds.
1823	55	26.9
1824	57	28
1825	62	28.97
1826	63	28.36
1827	62	31.9
1828	60	34.85
1829	56	40.9

The details respecting these engines are given by Mr. Henwood in Dr. Brewster's *Journal*, No. XIX, p. 45; and the same gentleman publishes regularly in the same Journal quarterly reports of the performance of the steam-engines in Cornwall.

Mr. Perkins' Steam Engine.

Although the high expectations which were entertained from Mr. Perkins' labours on the steam engine have not been realized, our readers will still look for some account of the method from which so much was anticipated.

The general construction of the apparatus is represented in Plate DIX, Fig. 6, where *a a a* represents the section of the *Generator* or boiler. It is a strong cylindrical vessel made of metal, about three inches thick in every part. This vessel is filled with water and heated in a cupola furnace fed by a blast, which almost entirely surrounds it. On the top of the generator there is an escape valve *b* pressed down by the loaded lever *c*, the pressure being capable of adjustment by placing the weight at different distances from the fulcrum. This valve admits the steam to the steam-pipe *d* which leads to the working cylinder. A lateral pipe *e*, intended merely for safety, is connected with the generator, and has an apparatus *f* attached to it for indicating the pressure. A forcing pump *h*, wrought by the engine, feeds the generator with water by the pipe *g*, which terminates near the bottom of the generator.

In order to generate steam, the generator is filled with water by the forcing pump *h*. When the heat of the surrounding furnace has raised the water to a temperature of 400 or 500 of Fahrenheit, an additional quantity of water is pumped into the generator, sufficient to force a portion of that which is already heated from under the loaded valve *b* at the steam-pipe *d*, where it instantly *flashes* into strong steam, which proceeds to the piston of the cylinder. The valve *b* is shown on an enlarged scale in Fig. 7. It is a spherical bulb falling into a concave seat in the lower part of the square chamber. The upper part of the valve is a cylindrical rod, on the top of which the weight of the pressing lever *e* is exerted. The lower part of the valve is a triangular stem sliding up and down in the cylindrical passage. When the additional quantity of water is injected into the generator as above described, the bulb of the valve rises from its seat, and a corresponding quantity of heated water passes up between the cylindrical passage, and the sides of the triangular stem into the square chamber, where, from the pressure no longer operating on that portion of the water, it becomes steam, as already mentioned.

For the renewal and the regular continuance of the operation, an adjusting weight *i* is placed on the handle of the pump, which is a small single stroke forcing pump with a weight *w* performing the office of an air-vessel. At the end of the pump handle is a chain *m* which is connected with a single crank movement, and thus by a corresponding adjustment between the escape valve *v*, the throttle valve (which is not shewn in the figure) and the weight *i*, a certain quantity of water is forced into the generator at every stroke of the pump, and a corresponding quantity forced from beneath the loaded valve *d* to become steam.

From the difficulty, we presume, of constructing generators of sufficient strength, Mr. Perkins has more recently substituted a numerous series of very thick and strong cast iron tubes of small bore, and all connected with each other, in place of his cylindrical generator.

Such is a brief account of Mr. Perkins's method of generating powerful steam. Among the practical difficulties which Mr. Perkins encountered was the difficulty of constructing generators of the requisite strength; but it is probable that the real causes of his failure were the great force which was lost by the injection of the cold water into the generator, and the loss contained by the passage of heat up the chimney.

Account of Mr. Scott's Engine without a Boiler.

In the year 1823, our ingenious countryman Mr. Alexander Scott of Ormiston, constructed a model of a steam-engine without a boiler, with which experiments were made in presence of several persons in his neighbourhood. Owing to accidental causes, the engine itself was not completed till 1829. The following account of it transmitted to the editor of this work by Mr. Scott, and published in the *Edinburgh*

Journal of Science, New Series, No. III, p. 21, will convey a clear idea of this important invention.

When water of a low temperature is forced by a pump into a small generator placed over a fire, every stroke of the pump tends to lower the temperature of the whole body of water. This led to devise a generator by which water of a low temperature can be forced into it without lowering the temperature of the hottest part of the water. In constructing a generator with that property, two truly flat circular patterns of wood were made, having each corresponding projecting parts. In one pattern a continued spiral groove was cut from the centre to nearly its circumference; the other pattern was left plain. Fig. 8, Plate DIX, represents the one, and Fig. 9 the other. Both these patterns were made twenty-one inches in diameter, exclusive of the projecting parts. The spiral grooved pattern was one inch and three quarters in thickness, and the plain pattern one inch and a quarter thick, as also were the projecting parts of both patterns. The spiral groove was cut half an inch in depth, half an inch wide at bottom, and seven-eighths of an inch at top. The ridge between the grooves was left half an inch in depth, half an inch in breadth at top, and seven-eighths of an inch at bottom. From these two patterns iron casts were taken. The faces of both these cast-iron plates were made truly flat, and a very small chiseled groove was cut along the middle of the ridge between the grooves, and a corresponding chiseled groove was cut in the inch and quarter thick plate. These two plates were then cemented together by means of well prepared iron cement, part of it filling the chiseled grooves in both plates; the projecting parts *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, Figs. 8 and 9, were bolted together by screw bolts, five-eighths of an inch square, made of the best iron; in all fifteen bolts, as marked by the small square bolt holes in Figs. 8 and 9; the projecting parts of Fig. 8 being all, except that marked *h*, one and a quarter of an inch in thickness, which leaves a space of half an inch between the projecting parts of the two plates, for the more effectually screwing the plates close together. These two plates when thus joined form only the one-half of the generator, as there is another half almost in every respect similar to be placed perpendicularly over the one described : having a strong cast-iron pillar with flanges, as represented by Fig. 10, placed in the centre between the halves : These flanges are strongly secured by four screw bolts to each of the halves of the generator. The centre pillar is twelve inches in height and four and a half inches in diameter, with a bore up its centre of one inch and a quarter in diameter.

Fig. 4 represents a section of the generator answering to the description already given, placed in a furnace, of which a section is also given.

The generator is supported in the furnace by cast-iron brackets represented by Figs. 12 and 13, built into the sides of the furnace for the projecting parts of the generator to rest on, where F, Fig. 11, is the fire place, A the ash-pit, and C part of the chimney. R represents part of the pipe that leads from the force pump to the generator, whence the water circulates round and round the spirals from the circumference to the centre of the under half of the generator, ascends the centre pillar P, then circulates outwards from the centre of the upper half of the generator to its circumference, and escapes by the pipe S, that leads to the cylinder of the engine. The pipe T is the one that conveys part of the escape steam from the cylinder into the chimney. This generator works a small high pressure engine, of which the following is a short description :

The frame of it is of cast-iron, of the form of the upper part of Mr. Maudslay's portable engine with its parallel motion. The piston of the cylinder is six inches in diameter, and the length of the cylinder permits the piston rod to make a stroke of seventeen inches. The steam is permitted to enter the cylinder alternately above and below the piston by means of a spring slide valve wrought by the engine, and has a stroke of one and two-eighths of an inch. The axis of the fly-wheel cranks, &c. is two inches and a quarter square ; the rounded parts two and one-eighth inches in diameter. The fly is seven hundred weight. and six feet in diameter. In the steam-pipe that leads from the generator to the cylinder, there is a three-way cock introduced, with a branch proceeding from it to the hot well of the engine, by which the steam may be permitted either to pass the cylinder, or by one-third turn of the cock into the hot well of the engine. This three-way cock answers for stopping or starting the engine. As there is no space in this kind of generator, as in common engine-boilers, for the steam to condense or expand, the common throttle valve is not applicable to this kind of generator ; but in place of it, a spring slide valve is introduced in the steam-pipe between the three-way cock and generator, with a branch from it communicating with the branch pipe that leads between the three-way cock and hot well. This slide valve is raised and lowered against a very acute angled aperture by means of centrifugal balls, so as to permit a necessary regulating quantity of steam to escape into the hot well. In the pipe by which the steam escapes from the cylinder into the chimney, there is a branch to the hot well ; in this branch there is a cock by which the temperature of the water in the hot well is regulated. The forcing pump is wrought by the engine, and supplies the generator with water from the hot well. In a side vessel that communicates with the hot well, there is a forcing pump wrought by hand for starting the engine. Into this vessel additional water enters to supply the engine, and where the height of the water in the hot well is regulated. As the engine is intended to work different kinds of machinery, either together or separately, different powers are required.

To produce these several powers, there is a short branch from the steam-pipe near the generator, that reaches to a convenient place, where a steel yard safety valve is placed. On the lever of this safety valve, the safety valve weight is to be hung at divisions marked on it answering to the power required, and a corresponding length of stroke is also to be given to the forcing pump of the engine.

The engine was first publicly tried in January 1828, before it was connected with machinery of any kind ; but that it might meet with some resistance, a friction bar of iron with a considerable pressure was applied to the periphery of the fly-wheel, when the engine made eighty-eight double strokes per minute.

The engine was lately tried connected with grinding and turning-lathe machinery, and at the same time it wrought cast-iron rollers bruising bleas for fire clay.

Although the bleas were very irregularly fed into the rollers, yet the engine continued to make sixty-four double strokes per minute. A greater number might have been obtained; but from the irregular manner the bleas was fed in, there was reason to fear that the main axis of the engine might give way.

On the bottom and sides of vessels that have been long used for boiling fresh water, a calcareous crust is generally formed more or less in thickness.

It is proposed, if it shall be found that the spiral grooved generators are liable to be incrusted in this manner, that a water-tight cistern be placed somewhat higher than the generator. This cistern is to be connected with the upper part of the generator by a pipe and stop-cock. There is also to be a branch pipe from the steam-pipe close to the under part of the generator, with a particular stop-cock, that when open, it shall cut off the communication between the generator and the slide valves. Let this cistern be filled brimful with water, and the cock at the bottom of the generator left open. If the cock of the cistern be opened, the whole water of the cistern will escape through the generator; and if the time it takes to escape be observed by a pendulum or stop-second watch, the repetition of this experiment at any time will show if the passage through the generator be contracted since last experiment. Should it be found to be so, it is then proposed to fill the generator with diluted muriatic acid, taking care to cut off the communication between it and the slide valves. After letting it remain in the generator a sufficient time, it is then to be washed out with warm water poured into the above-mentioned cistern. If the cistern be filled brimful it will serve to ascertain if the passage be clear, by observing the time it takes to pass through the generator. Repetitions of these experiments will undoubtedly free the generator of all calcareous matter. But as none of the strong acids act on the crust formed by sea water, it is therefore proposed to proceed in the same manner with diluted sulphuric acid, taking care never to give time for much crust to form by sea water, so that by the diluted sulphuric acid partly acting on the iron, it shall effect the removing of an imperfect crust produced from salt water; the generator to be always thoroughly washed out with warm water.

The length of time that this engine has been in constructing, gave ample time to devise improvements. Several were proposed, but few of them were thought of in time to be introduced without making material alterations on the parts made; such as improvements in the manner of constructing generators of greater strength, but of which it is unnecessary to lengthen this paper with a description. However, one thing may be mentioned, as it would add to the improvement of the engine. In place of working the escape steam slide valve by the immediate action of the centrifugal balls, it was proposed that the axis of a bevelled wheel should be turned by the machinery of the engine, and which is to turn other two bevelled wheels on one axis. These two last mentioned wheels are neither of them to be fixed to the axis, but both to slip round freely upon it, turning in contrary directions as they receive motion from the opposite sides of the first mentioned wheel. A locking stub box is fitted upon the axis between the two wheels, and can, by moving it one way or the other, be made to lock either of the wheels to the axis at the same time that it leaves the other disengaged. It is proposed that the centrifugal balls shall shift this stub box back or forward as their centrifugal motion shall be affected by the velocity that they receive from the engine. The axis of these two wheels is proposed to be so connected with the escape steam slide valve, that, on its turning one way round it shall raise the valve to let the steam escape, and by turning the contrary way, it shall depress the valve that less may escape; and it is further proposed, that there shall be spring sockets on the axis of the first wheel, to prevent any part giving way when the valve is fully wrought up or down. In like manner it is proposed to work the furnace damper for regulating the heat of the fire.

The engine, as now completed, is a handsome piece of well finished accurate workmanship, and performs its part admirably. The young man who made all the principal parts of the engine is a self-taught mechanic, and merits the highest praise for the ingenuity, elegance, and perfect workmanship which he has displayed upon it.

Account of Mr. G. Gurney's Tube Boiler.

Various attempts have been made to construct boilers with tubes, but practical difficulties occurred which the ablest engineers sought in vain to remove. These difficulties arise from the water being carried off along with the steam, which left the containing vessel dry, oxidated the metal, and produced hydrogen, the heat of which destroyed the packings of the joints in the pipes and the working cylinder;—from the deposition of earthy concretions in the tubes,—and from the destruction of the joints by the sudden and unequal expansion of the metal composing the boiler.

Mr. Gurney's boiler is constructed with the view of obviating this objection. It is shown in Plate DIX, Fig. 14 and 15, Fig. 14 being a section, and Fig. 15 a front elevation of the boiler. A section of one of the tubes is shown in Fig. 14 surrounding the flame. Each end of every tube opens into two cylindrical chambers *c c*, and these chambers communicate by pipes with the vertical chambers *a a*, which receive the steam and water generated in the pipes. Here the steam and water are separated, the steam rising to the top, and the water falling to the bottom. Hence these chambers are called *separators*. These separators are united with the top of a tube *b*, in the centre of which the safety-valve is placed. The injection pipe of the forcing pump is inserted into either of these chambers, *d* is a small well to receive any extraneous matter which may pass into the boiler, *e e* are the guage cocks for steam and water, the lower cock being the water level of the boiler. The fire-door is shown at *f*. Fig. 15 and 17 and 18, show the manner in which the tubes are fixed to the chamber *c*.

The incrustation of salt and its corrosive action on the tubes appeared at first hostile to the use of the boiler at sea; but Mr. Gurney has removed this objection by condensing the high pressure steam instead of blowing it off, and returning the water thus procured by means of a forcing pump into the boiler, so that by beginning with pure rain or distilled water, steam is continually generated without any great expenditure of fresh water, as the steam from the engine is not only condensed, but also a part of this procured from the fresh water which is successively employed in condensing it, and which without loss of power in a steam vessel can be led from the water thrown up by the paddle wheels to a cistern for the purpose. The following is the condenser employed by Mr. Gurney.

Description of Mr. Gurney's Condenser.

Mr. Gurney's Condenser is shown in Plate DIX, Fig. 19, 20, where *a* is a bent pipe joining the eduction pipe of the engine to the cone I of the condenser, which is a cylindrical vessel 3½ feet long, and 7 inches diameter inside, for a 10 horse engine. Within this cylinder 40 copper tubes five-eighths of an inch in diameter, are arranged in circles, and are inserted in plates at each end by steam tight joints as shown in Fig. 20. The nozle *c* is connected with a cold water pump which discharges about two gallons per minute for every horse power. In steam boats this is not necessary, as the water can be procured from the paddles. This water will rise in the cylinder so as to surround the tubes until it is ejected from the nozle *d*, from which it may return to the well or cistern. The steam which passes from the engine into the tubes is condensed before it reaches the lower cone *e* and falls into the close chamber below, from which it is carried by the suction pipe *g* to the injection pump of the boiler. When there is too little water in this chamber the ball of the cock falls and admits the proper quantity from the cylinder through the tube *i*. By the tube *k* air or vapour may be drawn out. Captain Ross, who saw this condenser in operation, is of opinion that it makes Mr. Gurney's boiler quite perfect for naval purposes.

Having thus described the most important improvements on the Steam Engine, we shall now give an account of some miscellaneous contrivances connected with it.

Miscellaneous contrivances connected with the Steam Engine.

Murray's Sliding Valve.—The idea of a sliding valve has been long ago suggested, and seems to have been first applied to the air pump by Lavoisier or some of his associates. Mr. Murray of Leeds, however, has the merit of having applied it with great ingenuity to the steam engine, and may be regarded as its real inventor. This valve is represented in section in Plate DIX, Fig. 21, and the object of it is to cover alternately the passages *a c*, *e b*. The sliding cover is put in motion by the rod *o*, which passes through a stuffing box. The steam from the boiler is introduced at S, passes through the opening *a* to the top of the cylinder, when the slide is down as shown in the figure, while the passage *c* to the condenser is open through the interior portion of the slide. When the slider is up the passage *b* to the bottom of the cylinder is open, and the passage *a* from the top, to *c*, the passage to the condenser is open. Owing to the pressure of the steam against the box, the friction of the valve is considerable. This disadvantage, however, has been remedied by Mr. Murdoch, who packs the slide, and this keeps out the steam. Messrs. Taylor and Martineau have substituted for the slide, pistons sliding in a pipe, which is a valuable improvement.

Sim's Valve.—This valve is shown in Plate DIX, Fig. 22, and has been extensively used in large engines. The seat is shown at *a a a*, *a′ a′ a′*, and is solid at *a a a*. Apertures are cut in its sides at *a′ a′ a′* for the passage of the steam, and at *a″ a″* is the beat, into which it is ground with emery. The valve *b b* is a plain cylinder very accurately bored, and packed at *d d* with the usual materials, the packing being kept in its proper place by the ring *e e*. A second ring *f f* rests on *e e*, and is kept in its place by the screws *g g*, which help also to keep the packing in a proper state of compression. The valve is lifted by the bar *c*. It is evident that the steam can exert no pressure to prevent the valve from being lifted, and when it is closed, the vapour has no power to open it. This valve answers its purpose so completely, that an infant might lift the valves of a 90 inch engine. It would be desirable to dispense with the packing, as it increases the dimensions of the valve. See Dr. Brewster's *Journal of Science*, No. XIX, p. 42.

Cartwright's Metallic Piston.—Mr. Cartwright took out a patent in 1797 for the method of using metal in place of elastic substances for the packing of pistons. This method is shown in Fig. 23, where *a a a* are six or more segments of rings made to fit the internal surface of the cylinder, with a second series *b b b* crossing the joints of the former. Each series of segments were pressed against each other, and against the cylinder with V springs, and by having two sets with the junction of the rings in the one, set opposite to the solid parts of the rings in the other set, any escape of steam out of the joints was prevented. The upper and under sides of the sets of segments were connected by plates to which the piston rod was united, as shown in the section.

Jessop's expanding Coil Piston.—This very ingenious contrivance was secured by patent in 1823, and is shown in Fig. 24. It consists of an elastic expanding coil of metal AA which winds round the body of the piston in a spiral form, as shown in the section at AA. BB is a bed of hemp packing which prevents the steam from passing at the joints, and presses the springs against the surface of the cylinder. The piston is kept tight by the pressure of the steam on the upper and under plates. Mr. Barton's metallic expanding piston is very ingenious, and has been improved by Tredgold; but we must refer for an account of it to the work of the latter on the Steam Engine, p. 228. Perkins' metallic piston, from which much has been expected, is considered inferior to those described. See the *Repertory of Patents*, vol. i, p. 224.

On the Application of the Steam Engine.

The Steam Engine is, of course, applicable to every purpose where mechanical power is required, but some of its applications have been of such vast importance to the progress of the useful arts, that they require to be specially noticed. The most important of these are as follows:

1. Raising of water.
2. Drawing ores and coals.
3. Driving cotton machinery.
4. Paper mills.
5. Thrashing mills.
6. Corn mills.
7. Iron manufactures, &c.

1. *Raising of Water.*—By means of a single steam engine acting expansively 280,000 cubic feet of water can be raised one foot high by one bushel of coals;

and an engine of one horse power working eleven and a half hours daily will raise 280,000 cubic feet of water one foot high in a day. It will cost 8*l.* per annum, for each horse power, to return the first cost and repairs. In raising water the stroke of a pump should not exceed eight feet, nor its diameter fourteen inches, and the velocity of the piston should not be greater than ninety-eight times the square root of the length of the stroke.

The quantity of water in cubic feet delivered at one stroke of a pump in the best order is $.00518\ l d^2$, l being the length of the stroke, and d the diameter of the pump in inches. The following table will show the quantity of work performed in 1826, at Wheel Hope, by one of the best Cornish engines made by Mr. Grose. The numbers are taken from a monthly report.

Diameter of cylinder	60 inches square.
Load per square inch on piston	8.37 lbs.
Length of stroke in cylinder	9 feet.
Number of strokes per minute	$5\frac{1}{2}$
Number of lifts, 1st 1 through 46 fathoms	5 feet.
——— 2d 1 — 11 —	2 —
——— 3d 1 — 11 —	2 —
Diameter of pump for 1st lift	15 inches.
——— 2d —	$12\frac{1}{3}$ —
——— 3d —	11 —
Consumption of coals	1.242 bushels.
Number of strokes	261,890
Length of stroke in pump	8 feet.
Number of pounds lifted one foot high by one bushel of coals	46,838,246

2. *Drawing Ores and Coals.*---The engines used for this purpose are double engines from twenty to thirty horse power. From three to seven cwt. is generally raised at once; and as the work is irregular, from stoppages and changes of motion, *one pound of coals* raises only about 70,000 pounds of ore.

3. *Driving Cotton Machinery.*---Double acting engines working expansively are best fitted for cotton mills. One horse power will drive one hundred spindles with cotton yarn and the preparatory machinery. The same power will work twelve power looms with preparation. If the day's work is eleven hours, ninety pounds of the best caking coal will be required for each horse power.

4. *Paper Mills.*---A beating machine requires a seven horse power, and the new machines for making paper a two or a two and a half horse-power.

5. *Thrashing Mills.*---Engines from 4 to 6 horse power are generally used. The feeding rollers perform from 35 to $47\frac{1}{2}$ revolutions per minute, their diameter is $3\frac{1}{2}$ inches, and their length from 4 to 5 feet. The straw rollers revolve 30 times per minute, and their diameter is $3\frac{1}{2}$ feet. The drum revolves 300 times in a minute, and is $3\frac{1}{2}$ feet in diameter. The quantity of wheat thrashed by a machine with feeding rollers 4 feet broad, varies according to its quality from 12 to 24 Winchester bushels per hour, and the quantity of oats per hour from 16 to 30 bushels. The power required is 100,000 pounds raised one foot per minute for thrashing alone, and 183,000 when winnowing machinery is also wrought. Each inch of the straw receives three strokes of the beaters. The stroke should be made with a velocity of 55 feet per second, or the beater should move 3300 feet per minute.

6. *Corn Mills.*---The double expansive engine is best fitted for corn mills. With low pressure steam it should grind 14 bushels of wheat for each bushel of coals when working in the best manner. The average however, will be $11\frac{1}{2}$ bushels. The power required to grind and dress a Winchester bushel of wheat per hour is 31,000 pounds raised one foot in a minute. The velocity of the circumference of the mill-stone should be 23 feet per second, and with that velocity a pair of 5 feet stones should grind 4 or 5 bushels per hour, according to the state of the grain.

7. *Iron Manufactures.*---In the iron manufactures the steam engine is applied to blowing machines, forge hammers, rolling, flatting and slitting mills. See our Articles Blowing *Machinery* and Iron.

Many of the other applications of steam will be learned from the following table given by Mr. Cleland, and showing the quantity of steam power used in Glasgow in April 1825.

	Horse Power.		Horse Power.
Spinning cotton,	893	Twisting yarn,	18
Weaving,	681	Smith work,	18
Raising water,	262	Drug grinding,	14
Bleaching & dyeing, Washing & dischars	206	Coach making,	12
		Glass grinding,	12
Calendering,	160	Grinding malt and pumping wash,	20
Corn grinding,	153		
Founding,	124	Grinding colours,	14
Distilling,	119	Veneer sawing,	10
Engine making,	68	Tambouring,	10
Chemical operations,	39	Wool-carding,	8
Machine making,	37	Pottery,	7

Sugar refining,	18	Gas,	4
Cutting wood,	18	Coppersmiths,	4
Lamp-black making,	18	Total,	3000

Besides these there are in the vicinity of Glasgow,
Collieries, 18, with 58 engines, of horse power, 1411
Quarries, 7, --- 7 ——— ——— 39

General Abstract.

	No. of Engines employed.	Horse Power.	Average Power of Engine.
In Manufactories,	176	3000	$16\frac{9}{10}$
In Collieries,	58	1417	$24\frac{3}{10}$
In Stone Quarries,	7	39	$5\frac{6}{10}$
In Steam Boats,	68	1926	$36\frac{3}{10}$
In Clyde Iron works,	1	60	
	310	6436	$20\frac{7}{10}$

In 1824 upwards of 200 steam engines were used in Manchester.

Mr. Cleland has added to the above interesting documents, the following comparison of the price of coals consumed by steam engines and the keep of horses.

A heavy horse working 10 hours will consume 15 lbs. avoirdupois of oats, and 14 lbs. of hay per day. An engine of 30 horse power, working 10 hours per day in a mill, will consume, on an average of summer and winter, about 4 tons of coal dross. The steam-boat Toward Castle, from Glasgow to Rothsay, and back again, a distance of about 80 miles, consumes $5\frac{1}{2}$ tons of hard coal in 12 hours.

These are some of the principal applications of the steam engine; but the most important of all is its application to Carriages and vessels, which is treated of in the separate Articles Steam-Boat and Steam-Carriage. For farther information on the subject of this section, see Tredgold on the *Steam-Engine*, sect. ix.

As the preceding article is intended only for the perusal of general readers, those who wish to prosecute the subject farther may consult the following works:—Switzer's *System of Hydrostatics;* Belidor's *Architecture Hydraulique;* Desagulier's *Experimental Philosophy;* Ferguson's *Lectures on Mechanics*, vol. i. p. 312; Smeaton's *Reports;* Prony's *Nouv. Architecture Hydraulique*; Robison's *Mechanical Philosophy*, vol. ii.; Stuart's *Descriptive History of the Steam Engine*, Lond. 1824; Montgery's *Notice Historique sur l' Invention des Machine-à-Vapeur;* Farey's *Treatise on the Steam Engine, Historical, Practical, and Descriptive*, Lond. 1827; Partington's *Historical and Practical Account of the Steam Engine;* Tredgold's *Steam Engine*, Lond. 1827; Lardner's *Popular Lectures on the Steam Engine*, Lond. 1828; Birkbeck and Aldcock *on the Steam Engine*.

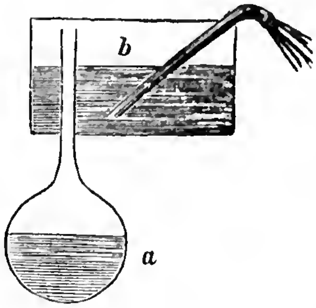
An account of the most recent improvements on the steam engine, as made in Cornwall by Mr. Henwood, will be found in Dr. Brewster's *Journal of Science*, No. XVIII. and No. XIX.

It is not only agreeable to know the gradual progress which all arts, sciences, and improvements have made, from the first rude attempts to perfection; but proper, in a work of this kind, to detail them. The author of the preceding article makes no mention of Hero of Alexandria, or of Porta the Italian, both of whom may be said to have invented steam engines, or at least to have demonstrated the elastic force and moving power of steam. The first lived about 130 years before the Christian era; and in his work entitled *Spiritalia,* describes a machine to which motion is to be given by the force of steam. It consisted of a hollow globe, having tubular arms extending in opposite directions, and having openings at different sides near their extremities. The globe was suspended upon centres, fixed upon pillars, one of which and one of the centres was hollow. Steam was introduced from a cauldron, and issuing through the hollow column and centre into the globe, passed through the arms into the open air, producing a rotary motion.

In the year 1560, Mathesius, a German, suggested the practicability of a plan by which steam could be employed. In Leipsic, a machine upon a similar plan to that of Hero was proposed to be substituted for the turnspit-dog, then in use.

Porta, a Neapolitan, published the account of his apparatus in 1606, in an Italian translation of Hero's work. The boiler *a* has a long neck, which passes through the bottom of the close cistern *b*, containing water. A bent pipe or syphon *c* is closely fitted into the top of the cistern, and descends nearly to the bottom. When the fire is lighted under *a*, the steam ascends into the cistern, presses upon the water, and forces it up the syphon *c*, whence it runs in a stream.

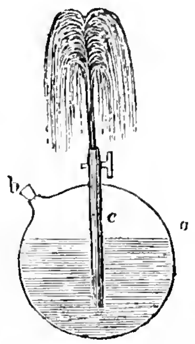
Mr. Ainger observes that this was an extraordinary suggestion, and it is surprising that the project was not sooner reduced to practice, than is found to be the case.



The contrivance is a great improvement on that of Hero (who proposed to use solar heat), because the steam from heated water in one vessel is made to drive up cold water from another vessel, instead of driving up the heated water from which the steam is produced. With this important modification, the apparatus resembles that of the Marquis of Worcester, in 1663, excepting only in the extent of its power.

In the year 1615, according to M. Arago, De Caus, a native of Normandy, published at Frankfort a work entitled *Les Raisons des forces mouvantes avec diverses Machines tant utiles que plaisantes,** &c., and dedicated it to Louis the XIII. The fifth theorem is thus headed: "*L'eau montera par aide du fous plus haut que son niveau;*"† and the explanation of this with a diagram exhibits a real steam engine, capable of producing a vacuum. This was forty-eight years prior to the appearance of the Marquis of Worcester's Century of Inventions, which was written in 1655, and first appeared in print in 1663.

The announcement forms the third of five modes of raising water. "Let there be a globe," he says, "*a*, having a valve *b*, to introduce water, and a tube *c*, soldered into the upper part of the ball, and descending nearly to the bottom: after having filled the ball with water, and well closed the valve, place it on the fire; then the heat, acting on the ball, will cause the water to ascend through the tube *c*."

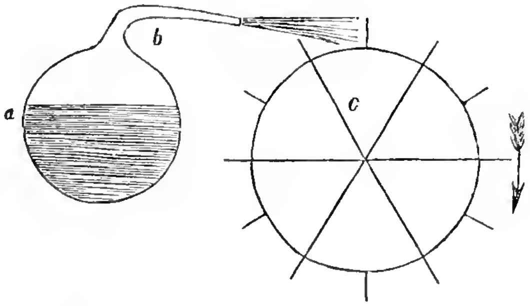


Mr. Angier says that this apparatus is so obviously inferior to that of Porta, which had appeared only nine years before, that it would be an insult to the reader to say why; and yet Mr. Arago rests his claim for the invention of the steam engine in France, on the part of De Caus, to this simple contrivance, and gives a diagram of it, not exactly like the one figured by De Caus, from whose work Mr. Angier faithfully copied the annexed figure.

Brancas published an account of his apparatus in 1629, in a work entitled "*Le Machine.*" The boiler *a* terminates with a bent tube *b*, from which the steam issues, and impinges upon the vanes of a wheel *c*, which receives motion in the direction of the arrow. This principle does not differ from the first

* The *proofs* or *account* of *moving forces with different machines equally useful* as *amusing.*
† *Water will show,* by *the aid* of *fire,* a *greater height than its level.*

apparatus of Hero, and the practical effect would probably be inferior.



The Marquis of Worcester, Newcomen, Savary, and others followed: an account of whose inventions is given in the preceding pages, and numerous other works.

Moreland's work referred to, p. 399, consists of thirty-eight pages in MS., written on vellum, richly illuminated, but the part which has reference to the steam engine occupies only four pages. It is also accompanied by a table of the sizes of cylinders, and the amount of water to be raised by a given force of steam. Moreland was presented to the French monarch in 1682, and the next year, his machine is said to have been exhibited at St. Germains. He can not however be entitled to the merit of an original, his apparatus having been evidently suggested by the work of the Marquis of Worcester.

The ingenious Papin then follows, who is noticed in p. 399: M. Arago, in the "Annuaire du Bureau des Longitudes" for 1829, gives a paper on the early history of the steam engine, and claims for his countryman the honor of completing the invention: but Mr. Ainger has critically analyzed that paper, and asserts that the apparatus, upon which he founds the claim for Papin, was never made as a working machine; and does nothing more than illustrate a well known physical fact. That a vacuum was left by condensed steam, was known from the time of Hero at least. That the air, or some other power, would force a liquid or solid body into a vacuum, was equally well known. Mr. Ainger farther asserts that Papin never experimented on such an apparatus as Mr. Arago ascribes to him; never even suggested such a one: and that the two diagrams, given by him of Papin's invention in 1690, are portraits of the apparatus of Newcomen, made fifteen years afterwards, viz. in 1705;* yet notwithstanding this unfair conduct, Mr. Arago complains of professor Robinson, who in his account of the steam engine, merely refers to a work of Papin's published in 1707,† nine years after Savary's patent, describing it as his first publication, and actually denies the existence of those of 1690 and 1695, although he might have found an analysis of the latter in the Philosophical Transactions of the Royal Society of London, for March 1697, a whole year before Savary's engine was heard of. In another instance he is said to have post-dated a little work of Papin's seventeen years, in order to attribute the merit of his observations to Dr. Hooke of England. These misstatements and errors have been copied, by professor Millington, Dr. Lardner (the author of the article on Steam Engines in Rees's Cyclopœdia) and the writer of the preceding article, who acknowledges, p. 400, that he also had been led, upon the authority of Dr. Robinson, to do injustice to the genius of Papin, when he had occasion to discuss the subject in another work. He however most unaccountably omits to notice the invention of a Safety Valve by Papin, to be attached to his digester; without which, as Mr. Galloway truly remarks, "steam would 'ere this, long have been abandoned, as a most dangerous and ungovernable agent, and entitles him to universal admiration; since it has contributed more than any single addition or improvement to the maturity of the steam engine."

In the preceding article of the Encyclopedia, no mention is made of American steam-engines, although Dr. Thornton's account of Fitch's early and successful experiments in navigating the Delaware with a steam boat was published in the London Monthly Magazine for October 1815;‡ and the history of Oliver Evans's progressive knowledge of the powers of steam; his various propositions for its use in driving carriages and boats; and the description, with a plate of his Columbian steam engine, was published by Elijah Galloway, in his "History of the Steam Engine," London 1827; a work, by the way, which is overlooked in the reference to those recommended for consultation at the close of the foregoing paper. The great merit of our ingenious countryman Evans, for his numerous mechanical improvements, and for the benefits which he has conferred upon the United States by his steam engine, entitle him to the gratitude of the present and future generations, and to a republication in this work of the record he has left of them.

His inventive genius has done more for the United States than any other, living or dead, and his improvements would have greatly added to the riches of our country, long before they began to operate, had he not been prevented from bringing them into use by his narrow circumstances, and the want of a liberal patron, to enable him to force them on the public, without waiting for the slowly acquired confidence of a people beyond whose intellects, on the subject of steam, he was full half a century in advance.

Evans could not have heard of the first high pressure engine constructed by Leupold the German in 1720, for there was not one in the United States to give him any advice; and it is known, that the work of that mechanician has only been recently introduced into the country by a German artist. The merit of Evans was therefore his own. His claim was for the "application of high elastic steam, the great advantage of which, he says, I had discovered, demonstrated, explained, and made known. I have dispensed with the heavy beam, condenser, and air pump, and simplified

* Franklin Journal, 4 vol. 1829, p. 363.

† In this publication Papin abandoned his cylinder and piston, and proposed another plan, copied unquestionably from Savary, and altered, as is universally admitted (according to Mr. Arago), for the worse.

‡ See p. 258, of this volume.

the construction of the boiler, cylinder, piston, and working gears: my plan requires a small forcing pump to supply the boiler. Thus, I have produced an engine ten times as powerful, more governable, and easier varied to suit any taste assigned to it, than that of Bolton and Watt: it can be constructed at half the price, and will expend only one third the fuel to do as much work as theirs."* His patent was taken out in 1801, one year before the date of Messrs Trevithick's and Vivian's, for a high pressure steam engine in England.

No man can pretend to compete with Evans, except Fulton, and even the wealth produced by his successful use of steam in navigation, cannot exceed that arising from the improvements on milling by Evans. In point of originality there can be no question as to the one to whom the honour is due; for while Fulton was a child, Evans, from the mere force of his genius, after hearing of the immense power of steam exhibited in a boyish frolic, with a gun barrel, followed up the principle, and in 1792 he filed in the patent office drawings and specifications of his principles, with a view to secure to himself at a future time the right to his discoveries, when he should be enabled to put them to the test, and perfect them. Twenty-one years before Fulton applied Bolton and Watts' low pressure engine to boats, he pronounced upon the extensive utility of steam, not only in navigating boats, but in propelling land carriages, and the driving of machinery, and actually demonstrated the truth of his theory in Philadelphia, in respect to the last mentioned object in 1801, and in reference to the two first, he proved it three years before Mr. Fulton had his first boat in operation in the North River, which was in the summer of 1807. Thus, in the opinion of Mr. Galloway the British engineer, "he fully established his claim to the first contrivance of a practicable steam boat."†

About the year 1772, being then an apprentice to a wheel-wright, or wagon-maker, I laboured to discover some means of propelling land carriages, without animal power. All the modes that have since been tried (so far as I have have heard of them) such as wind, treadles with ratched wheels, crank tooth, &c. to be wrought by men, presented themselves to my mind, but were considered as too futile to deserve an experiment; and I concluded that such motion was impossible for want of a suitable original power.

But one of my brothers, on a Christmas evening, informed me that he had that day been in company with a neighbouring blacksmith's boy; who, for amusement, had stopped up the touch-hole of a gun barrel, then put in about a gill of water and rammed down a tight wad—after which they put the breech in the smith's fire; when it discharged itself with as loud a *crack* as if it had been loaded with powder.

It immediately occurred to me that here was the power to propel any wagon, if I could only apply it; and I sat myself to work to find out the means. I laboured for some time without success. At length a book fell into my hands describing the old atmospheric *steam engine.* I was astonished to observe that they had so far erred as to use the steam only to form a vacuum to apply the mere pressure of the atmosphere, instead of applying the elastic power of the steam for original motion; the power of which I supposed irresistible.

I renewed my studies with increased ardour, and soon declared that I could make *steam wagons*, and endeavoured to communicate my ideas to others; but however practicable the thing appeared to me, my object only excited the ridicule of those to whom it was made known. But I persevered in my belief, and confirmed it by experiments that satisfied me of its reality.

In the year 1786 I petitioned the legislature of Pennsylvania for the exclusive right to use my improvements in flour mills, as also *steam wagons, in that state.* The committee to whom the petition was referred heard me very patiently while I described the *mill* improvements, but my representations concerning *steam wagons* made them think me insane. They, however, reported favourably respecting my improvements in the manufacture of flour, and passed an act granting me the exclusive use of them as prayed for. This act is dated March ——, 1787. But no notice is taken of the steam wagons.

A similar petition was also presented to the legislature of Maryland. Mr. Jesse Hollingsworth, from Baltimore, was one of the committee appointed to hear me, and report on the case. I candidly informed this committee of the fate of my application to the legislature of Pennsylvania, respecting the steam wagons—declaring at the same time, without the encouragement prayed for, I would never attempt to make them; but that, if they would secure to me the right as requested, I would, as soon as I could, apply the principle to practice; and I explained to them the great elastic power of steam, as well as my mode of applying it to propel wagons. Mr. Hollingsworth very prudently observed, that the grant could injure no one, for he did not think that any man in the world had thought of such a thing before: he therefore wished the encouragement might be afforded, as there was a prospect that it would produce something useful. This kind of argument had the desired effect, and a favourable report was made, May 21, 1787, granting to me, my heirs and assigns, for 14 years, the exclusive right to make and use my improvements in flour mills and the steam wagons, in that state. From that period I have felt myself bound in honour to the state of Maryland to produce a steam wagon, as soon as I could conveniently do it.

In the year 1789, I paid a visit to Benjamin Chandlee and sons, of Nottingham, Chester county, Pennsylvania, clock-makers, men celebrated for their ingenuity, with a view to induce them to join me in the expense and profits of the project. I showed to them my draughts, with the plan, of the engine, and explained the expansive power of steam; all which they appeared to understand, but fearful of the expense and difficulties attending it, declined the concern. However they certified that I had shown to them the drawings and explained the powers, &c.

In the same year, I went to Ellicott's mills on the

* Steam Engineer's Guide, p. 173.

† During this application to the legislature of Maryland, while Mr. Evans was explaining the principles of his intentions to several gentlemen, a person present asked him "how he could get out of the way of other wagons?" Mr. E. replied, "why sir, if you were the wagoner, and did not give me room to pass, I would crush you and your wagon to the earth," which so completely turned the laugh, that the would-be-wag was silent afterwards.—*Patent Right Oppression Exposed, Philadelphia*, 1813, p. 26.

Patapsco, near Baltimore, for the purpose of persuading Messrs. Jonathan Ellicott and brothers, and connections (who were equally famous for their ingenuity) to join me in the expense and profits of making and using steam wagons. I also showed to them my drawings, and minutely explained to them the powers of steam. They appeared fully to comprehend all I said, and in return informed me of some experiments they themselves had made, one of which they showed me. They placed a gun-barrel, having a hollow arm, with a small hole on one side at the end of the arm, similar to Barker's rotary tube-mill, as described in the books; a gill of water put into this barrel, with fire applied to the breech, caused the steam to issue from the end of the arm with such force as, by re-action, to cause the machine to revolve, as I judged, about one thousand times in a minute, for the space of about five minutes, and with considerable force, for so small a machine. I tarried here two days (May 10 and 11, 1789) using my best efforts to convince them of the possibility and practicability of propelling wagons, on good turnpike roads, by the great elastic power of steam. But they also feared the expense and difficulty of the execution, and declined the proposition. Yet they heartily esteemed my improvements in the manufacture of flour, and adopted them in their mills, as well as recommended them to others.

In the same year I communicated my project and explained my principles to Levi Hollingsworth.* He appeared to understand them; but declined a partnership in the scheme, for the same reasons as the former.

From the time of my discovering the principles and the means of applying them, I often endeavoured to communicate them to those I believed might be interested in their application to wagons or boats. But very few could understand my explanations, and I could find no one willing to risque the expense of the experiment.

In the year 1785 or 6, before I had petitioned the legislatures, I fell in company with Mr. Samuel Jackson, of Redstone; and learning of him that he resided on the western waters, I endeavoured to impress upon his mind the great utility and high importance of *steam boats*, to be propelled on them; telling him that I had discovered a steam engine so powerful, according to its weight, that it would, by means of *paddle wheels* (which I described to him) readily drive a vessel against the current of those waters with so great speed as to be highly beneficial. Mr. Jackson proves that he understood me well, for he has lately written letters, declaring that about twenty-six years before their date, I did describe to him the principles of the steam engine that I have since put into operation to drive mills, which he has seen—and that I also explained to him my plan for propelling boats by my steam engine, with *paddle wheels*, describing the very kind of wheels now used for this purpose; and that I then declared to him my intention to apply my engine to this particular object, as soon as my pecuniary circumstances would permit.

In the year 1800 or 1801, never having found a man willing to contribute to the expense, or even to encourage me to risque it myself, it occurred to me that though I was then in full health, I might be suddenly carried off by the yellow fever, that had so often visited our city (Philadelphia), or by some other disease or casualty to which all are liable, and that I had not yet discharged my debt of honour to the state of Maryland by producing the steam wagon. I determined, therefore, to set to work the next day and construct one. I first waited upon Mr. Robert Patterson, professor of mathematics in the university of Pennsylvania, and explained to him my principles, as I also did to Mr. Charles Taylor, steam engineer, from England. They both declared these principles to be new to them, and highly worthy of a fair experiment, advising me without delay to prove them; in hopes I might produce a more simple, cheap and powerful steam engine than any in use. These were the only persons who had such confidence, or afforded me such advice. I also communicated my plans to B. H. Latrobe, at the same time, who publicly pronounced them chimerical, and attempted to demonstrate the absurdity of my principles, in his report to the *American Philosophical Society* on steam engines;† in which same report he also attempts to show the impossibility of making steam boats useful, on account of the weight of the engine; and I was one of the persons alluded to, as being seized with the *steam mania*, conceiving that wagons and boats could be propelled by steam engines. The liberality of the members of the society caused them to reject that part of his report which he designed as demonstrative of the absurdity of my principles; saying they had no right to set up their opinion as a stumbling block in the road of any exertions to make a discovery. They said, I might produce something useful, and ordered it to be stricken out. What a pity they did not also reject his demonstrations respecting steam boats! for notwithstanding them, they have run, are now running, and will run: so has my engine, and all its principles completely succeeded—and *so will land carriages as soon as these principles are applied to them, as explained to the legislature of Maryland in* 1787, *and to others long before.*

In consequence of the determination above alluded to, I hired hands and went to work to make a steam wagon, and had made considerable progress in the undertaking, when the thought struck me that as my steam engine was entirely different in form as well as in its principles from all others in use, that I could get a patent for it, and apply it to mills more profitably than to wagons; for until now I apprehended that as steam mills had been used in England, I could only obtain a patent for wagons and boats. I stopped the work immediately, and discharged my hands, until I could arrange my engine for mills, laying aside the steam wagon for a time of more leisure.

Two weeks afterwards, I commenced the construction of a small engine for a mill to grind plaister of Paris—the cylinder six inches in diameter, and stroke

* I certify that OLIVER EVANS did about the year 1789 communicate a project to me, of propelling land carriages by power of steam, and did solicit me to join him in the costs and profits of the same. LEVI HOLLINGSWORTH.
Baltimore, November 16, 1812.

I do certify that some time about the year 1781, 31 years ago, OLIVER EVANS, in conversation with me, declared, that by the power of steam he could drive any thing—wagons, mills or vessels forward, by the same power, &c. ENOCH ANDERSON.
November 15, 1812.

† Mr. Latrobe's paper is in the 6th Vol. of the Society's Transactions, page 89.

of the piston eighteen inches—believing that with $1000 I could fully try the experiment. But before I was done with experiments, I found that I had expended $3,700—all that I could command. I had now to begin the world anew at the age of forty-eight, with a large family to support. I had calculated that if I failed in my experiment, the credit I had would be entirely lost; and without money or credit, at my advanced age, with many heavy encumbrances, my way through life appeared dark and gloomy indeed. But I succeeded perfectly with my little engine, and preserved my credit. I could break and grind 300 bushels of plaister of Paris, or 12 tons, in 24 hours; and to show its operations more fully to the public, I applied it to saw stone in Market-street, where the driving of twelve saws, in heavy frames, sawing at the rate of 100 feet of marble stone in 12 hours, made a great show, and excited much attention. I thought this was sufficient to convince the thousands of spectators of the utility of my discovery: but I frequently heard them inquire if the power could be applied to saw timber as well as stone, to grind grain, propel boats, &c. and though I answered in the affirmative, I found they still doubted. I therefore determined to apply my engine to all new uses, to introduce it and them to the public.*

This experiment completely tested the correctness of my principles, according to my most sanguine hopes. The power of my engine rises in a geometrical proportion, while the consumption of fuel has only an arithmetical ratio; in such proportion that every time I added one fourth more to the consumption of fuel, the powers of the engine were doubled; and that twice the quantity of fuel required to drive one saw would drive 16 saws, at least; for when I drove two saws the consumption was 8 bushels [coal] in 12 hours, but, when twelve saws were driven, the consumption was not more than 10 bushels; so that the more we resist the steam the greater is the effect of the engine. On these principles, very light, but powerful engines, can be made, suitable for propelling boats and land carriages, without the great incumbrance of their own weight, as mentioned in Mr. Latrobe's demonstrations.

In the year 1804. I constructed at my works, situate a mile and a half from the water, by order of the board of health of the city of Philadelphia, a machine for cleansing docks. It consisted of a large flatt, or scow, with a steam engine of the power of five horses on board, to work machinery to raise the mud into flatts. This was a fine opportunity to show the public that my engine could propel both land and water carriages, and I resolved to do it. When the work was finished, I put wheels under it, and though it was equal in weight to *two hundred barrels of flour*, and the wheels fixed with wooden axletrees, for this temporary purpose, in a very rough manner, and with great friction, of course, yet with this small engine I transported my great burthen to the Schuylkill with ease; and, when it was launched in the water, I fixed a paddle wheel at the stern, and drove it down the Schuylkill to the Delaware, and up the Delaware to the city [14 or 15 miles, leaving all the vessels going up, behind me, at least half way, the wind being a-head, and in the presence of thousands of spectators, a sight which I suppose would have convinced them of the practicability of both steam carriages and steam boats. But in this I was sadly disappointed, for they made no allowance for the disproportion of the engine to its great load, nor for the temporary manner in which the machinery was fixed, nor the great friction, ill form of the boat, &c., but supposed that it was the utmost I could do. Had I been patronised as Mr. Fulton was by the state of New-York, with the exclusive right for thirty years, and by a Mr. Livingston, with thirty thousand dollars to make the experiment, I might have showed steam boats in full operation long before Mr. Fulton began his boat, which was finished in 1807, twenty years after I petitioned the legislature of Pennsylvania, and three years after the above mentioned experiment.]†

Some wise men undertook to ridicule my experiment of propelling this great weight on land, because the motion was too slow to be useful. I silenced them by answering, that I would make a carriage, to be propelled by steam, for a bet of $3000, to run upon a level road against the swiftest horse they would produce. *I was then as confident, as I am now, that such velocity could be given to carriages.*

Having no doubt of the great utility of steam carriages on good turnpike roads, with proper arrangements for supplying them with water and fuel, and believing that all turnpike companies were deeply interested in putting them into operation, because they would smooth and mend the roads, instead of injuring them, as the narrow wheels do, on the 26th of September 1804, I submitted to the consideration of the Lancaster turnpike company, a statement of the costs and profits of a steam carriage to carry 100 barrels of flour, 50 miles in 24 hours—tending to show, that one such steam carriage would make more nett profits than 10 wagons drawn by five horses each, on a good turnpike road, and offering to build such a carriage at a very low price. My address closed as follows:

"It is too much for an individual to put in operation every improvement which he may invent.

"I have no doubt but that my engines will propel boats against the current of the Mississippi, and WAGONS ON TURNPIKE ROADS, WITH GREAT PROFIT. I now call upon those, whose interest it is, to carry this invention into effect. All which is respectfully submitted for your consideration."

In the year 1805 I published a book‡ describing the principles of my steam engine, with directions for working it, when applied to propel boats against the current of the Mississippi, and carriages on turnpike roads. And I am still willing to make a steam carriage that will run 15 miles an hour, on good level

* While Mr. Evans was exhibiting the little steam engine, he discovered the chairman of the committee of the Pennsylvania legislature, to whom his petition had been referred in 1786, and thus addressed him. "Sir, this steam engine works on the principles with which I had intended to propel my steam carriages when I petitioned the legislature, and which I endeavoured to explain to the committee. If you had granted me then the exclusive right for twenty-five years, it might have been driving wagons, boats, and mills, many years ago." His reply was "to tell the truth, Mr. Evans, we thought you were deranged, when you spoke of making steam wagons."

† Patent Right Oppression Exposed, p. 168. Philadelphia, 1813.

‡ Steam Engineer's Guide.

rail ways, on condition that I have double price if it shall run with that velocity, and nothing for it, if it shall not come up to that velocity. What can an inventor do more than to insure the performance of his inventions? Or, I will make the engine and apparatus, at a fair price, and *warrant* its utility for the purpose of conveying heavy burthens on good turnpike roads.

I feel it just to declare that, with Mr. Latrobe, I myself did believe, that with the ponderous and feeble steam engine, now used in boats, they could never be made useful in competition with sail boats, or to ascend the Mississippi, esteeming the current more powerful than it is. But I rejoice that, with him I have been mistaken; for I have lived to see boats succeed well with those engines; and I still hope to see them so completely excelled and out-run by using my engines, as to induce the proprietors to exchange the old for the new; more cheap and more powerful principles.

When we reflect upon the obstinate opposition that has been made by a great majority to every step towards improvement; from bad roads to turnpikes, from turnpikes to canals, from canals to rail-ways for horse carriages, it is too much to expect the monstrous leap from bad roads to rail-ways for steam carriages, at once. One step in a generation is all that we can hope for. If the present shall adopt canals, the next may try the rail-ways with horses, and the third generation use the steam carriages.

But why may not the present generation, who have already good turnpikes, make the experiment of using steam carriages upon them? They will assuredly effect the movement of heavy burthens, with a slow motion, of two and a half miles an hour; and as their progress need not be interrupted, they may travel fifty or sixty miles in the 24 hours. This is all that I hope to see in my time, and though I never expect to be concerned in any business requiring the regular transportation of heavy burthens (on land), because if I am connected in the affairs of a mill it shall be driven by steam, and placed on some navigable water, to save land carriage---yet I certainly intend, as soon as I can make it convenient, to build a steam carriage that will run on good turnpike roads, on my own account, if no other person will engage in it; and I do verily believe that the time will come when carriages propelled by steam will be in *general use*, as well for the transportation of passengers as goods, travelling at the rate of fifteen miles an hour, or 300 miles per day.

It appears necessary to give the reader some idea of the principles of the steam engine which is to produce such novel and strange effects; and this I will endeavour to do in as few words as I can, by showing the extent to which the principles are applied already.

To make steam as irresistible or powerful as gunpowder, we have only to confine and increase the heat by fuel to the boiler. A steam engine with a working cylinder only nine inches in diameter, and a stroke of the piston three feet, will exert a power sufficient to lift from 3,000 to 10,000 pounds perpendicularly, two and a half miles per hour. This power applied to propel a carriage on level roads or rail-ways, would drive a very great weight with much velocity, before the friction of the axletree or resistance of the atmosphere would balance it.

This is not speculative theory. The principles are now in practice, driving a saw-mill at Manchacks on the Mississippi; two at Natchez, one of which is capable of sawing 5000 feet of boards in 12 hours; a mill at Pittsburgh, able to grind 20 bushels of grain per hour; one at Marietta of equal powers; one at Lexington, Ky. of the same powers; one, a paper mill, of the same; one of one fourth the power at Pittsburgh; one at the same place of three and a half times the power, for the forge, and for rolling and splitting sheet iron: one of the power of 24 horses at Middletown, Conn. driving the machinery of a cloth manufactory; two at Philadelphia of the power of five or six horses; and many making for different purposes: the principles applying to all purposes where power is wanted.

OLIVER EVANS.

Nov. 13, 1812.

Columbian Steam Engine.

EXPLANATION.---Plate 510. No. 2.

A, the boiler; B, the working cylinder; C, the lever beam; D, the fly-wheel; E, the condenser; F, the water-pump; G, the supply pump; H, the furnace; I, the chimney flue; K, the safety-valve, which may be loaded with 100 or 150 *lbs.* to the inch area; it will never need more, and it must never be fastened down.

OPERATION.

The boiler being filled with pure water as high as the dotted line, and the fire applied, the smoke enters the centre flue, which passes through the centre of the water to ascend the flue I, and thus acts on a large surface.

When the steam lifts the safety-valve, it is then let into the cylinder by opening the throttle-valve, to drive the piston up and down, which, by rod 1, gives motion to the fly-wheel, and wheel 2 gives motion to a shaft, passing through the posts, to turn the spindle of the rotary-valves 3, 8, which lets the steam both off and on the cylinder at the proper time.

The steam escaping by pipe 4, curved and immersed in the water in box E, which is supplied by pump F, it is condensed, and the water formed descends by pipe 5 into supply pump G, and is forced into the boiler again by pipe 6.

But boiling decomposes water, slowly changing it into air incondensible. Therefore the shifting valve 7 is necessary. This valve lifts at every puff of steam, and a small quantity of air escapes; and it shuts, and a vacuum is instantly formed, as the crank passes the dead points.

The small waste of water may be supplied by condensing part of the steam rising from the condensing water, to run down the pipe 9, through a hole in the key of a stop-cock, $\frac{1}{32}$ parts of an inch diameter. A small hole indeed to supply a boiler of twenty horses power.

No sediment can accumulate in the boiler, it being supplied by distilled water. Therefore it will last much longer, and require less fuel than others. Muddy, limestone, or salt water, or the juice of the sugar cane, &c. &c. may be used to condense; and as the engine works equally well while we boil away the condensing water, we may boil for salt, sugar, &c. in working the engine,—thus using the fuel for double purposes.

If the steam be confined by the load on the safety-valve, to raise its power to 100 pounds to the inch, area of the piston and the cylinder be nine inches in diameter, and the stroke of the piston three feet, the power will equal that of twenty horses, and will grind 20 bushels of grain per hour, or saw 5,000 feet of boards in 12 hours. If the steam be confined by 150 pounds, the power of the engine will be equal to 30 horses, when the steam is shut off at one third of the stroke, and striking thirty-six strokes per minute.---Double strokes double the power.

The more the steam is confined, and the shorter it be shut off by the regulator 8, the greater will be the power obtained by the fuel. For every addition of 30 degrees heat to the water doubles the power. So that doubling the heat of the water increases the power about 100 times. On these principles fuel may be lessened to one third part consumed by other engines. This engine is not more than one fourth the weight of others; is more simple, durable, and cheap, and more suitable for every purpose; especially for propelling boats and LAND CARRIAGES. It requires no more water than the fuel will evaporate in steam, and this steam may be employed to warm the apartments of factories; or the condenser E could be used as a still to distil spirits; or a vat for paper making, boiler in a brewery, dye factory, &c. &c.

To the preceding account of Mr. Evans, the following may be added, taken from the preface to "the Steam Engineer's Guide."

In the year 1787, Mr. Evans explained to Captain Masters at Annapolis, Maryland, at his request, the principles of his Columbian Steam Engine, that he might communicate them to the people of England, to propel carriages and boats: and in 1794 or 1795, he sent drawings and descriptions to England by Joseph Stacey Sampson, of Boston, to endeavour to get some one to take out a patent there on shares with him; but he wrote from London that he could find no one to believe that the scheme would prove useful. Mr. Sampson died in London. In 1803 he entered into a contract with Mr. Edwards, engineer from England, and spent two months in furnishing him with complete drawings and descriptions of his engine, inexhaustible steam engine, and volcanic steam engine, all of which he said he could set up with his own hands. His Columbian high pressure engine was erected in Philadelphia in 1801, and in 1802 Messrs. Trevethick and Vivian took out their patent in England for a high pressure engine, which Mr. Galloway says, "has been found the most compact, simple, and effective engine perhaps ever known."

The following handbill was published by Mr Evans as a circular, and it will be useful to insert it on the present occasion. He may unduly estimate the economy of his engine, but if he is wrong, as much may be said for several philosophers who have undertaken to give tables of the expansive power of steam, no two of whom agree as to the results of their experiments or calculations.

Philadelphia, October 28th, 1817.

The subscriber continues to manufacture his Columbian Steam Engines, containing the following peculiar properties: viz.

1. It operates on the great advantageous principle of nature. As the heat is increased arithmetically, the elastic power of the steam is increased geometrically; every addition of about thirty degrees heat in water doubles the elastic power of the steam. Or, in other words, very little increase of heat produces great increase of power; doubling the consumption of fuel in a given time, produces about sixteen times the power and effect in the same engine. Thus it enables the small, simple and light steam engine, to do work equal to the large, complex, expensive and ponderous one, with about half the consumption of fuel.

2. It is constructed on the true principles of nature. All its parts are of a circular form, that cannot be bent and changed so as to break and explode, by the elastic power. It will therefore bear greater elastic power than boilers of other forms, in the proportion that a bar of iron will bear more pulling straight endwise, than it will on its middle, to bend and break it, when laid horizontally, supported at the ends; above one hundred times the power that any other form will bear.

3. The boiler being constructed of sheets rivetted together, of circular forms, it is impossible to make every part of equal strength. And the pressure of the steam, acting equally on every part, the weakest part will yield first, by a very small opening, to let the power of the steam or water escape, which will extinguish or check the fire, and stop all danger. It is therefore impossible to explode the boiler in so dangerous a degree as others do, by bending and breaking, in changing their form to a circle, by the elastic power of steam, which rises gradually.

4. The greater the elastic power, and the hotter the water in the boiler, the less will be its heat at the small distance of two or three feet, issuing from one of these small apertures, that will first yield; because the very instant it issues, the elastic power in the hot water explodes, and disperses the steam in mist so thin, and mixing with the air, that it instantly gives out its heat, and is reduced below the scalding degree, at the distance of three feet.* No injury has been done in any of the numerous instances where such leaks have yielded, in boilers worn by use, or burnt out; yielding so often that new ones have been made. Nor need any danger be apprehended, as it is evident that the boiler cannot be exploded.

5. It requires no more water than is boiled into steam. And the boiler may be made inexhaustible, by letting the steam that escapes from the engine pass into a tight vessel; there to be condensed into water again, by its own pressure, and the water may be returned to the boiler to supply it. This vessel may be a tight tube, passing through all the apartments of a manufactory to warm them, or to heat water. And thus the fuel may be applied to double purpose in many instances.

6. The boiler generates more steam than others, being so formed, that sediment does not adhere to its bottom, to form a non-conductor, and cause it to burn out; and it is well planned to receive the heat and retain it in the water, until a great elastic power is obtained.

7. It is less complex, and more easily kept in order, repaired, understood, and attended.

Those who may want a steam engine for any use,

* This may be tried and proved, by opening the water-guage cock.

are not expected to believe implicitly, but are requested to hold in suspense, *assertions* made by persons ignorant of the principles and properties of the engine, until they inquire for themselves, respecting some of the many Columbian Steam Engines now in use; or visit one personally, and they will find it to contain all those properties; and to be preferable for the following purposes; viz.

Steam Boats. It being lighter, more powerful, more governable; to vary the power, to stem the various currents, consuming and carrying less fuel and water; will carry *more* freight or passengers; and ascend currents, or perform any passage in *less* time.

And for salt or turbid waters, such as bays, and the Mississippi, the inexhaustible principle may be used; the boiler may be filled with pure fresh water, and a pure supply be obtained from steam, arising from the salt or turbid water used outside, to condense the steam in the tight vessel. Iron boilers will then suit better than copper, and there will be no danger from explosion, nor of being scalded by the small leaks.

The difference in the expense of fuel, of the profits of passengers, freight and time, will amount annually, to more than the whole price and expense of the engine, on many waters, or for many purposes.

Manufactories. As the steam may be applied to heat the water, and to warm all the apartments.

Paper Mills. The steam may be applied to heat the vats, and warm the drying rooms.

Saw or *Grinding Mills*, *Furnaces*, or *Forges*. As so little water is necessary, that it can be set at the ore banks, or in any convenient place, where a well can be had.

For every other purpose where power may be wanted, there is a difference between this and the low pressure engines, equal to its full price, in a few years use.

Several persons have begun to infringe my rights, having found that what I had published was true; viz. That as the elastic power of steam should be increased, the power of the engine and speed of the boat would be increased, without a proportionate increase of the consumption of fuel.

Some construct and use my specified boiler, in whole, or in part, by using high pressure steam to a condensing engine, to evade my rights. *Others have constructed boilers of different forms*, which they believed to be equally safe and strong: and attempting to use high pressure steam, until they exploded their boilers; neither of which can succeed perfectly. And they unitedly proclaimed, that it was the invention of high pressure, which caused the injury; to my very great damage, by depriving me of the profits of my invention, and to the injury of the public, by depriving people of the benefits of the useful discovery. And I am constrained to put the engine of the patent laws of the United States in force and motion, which will probably overtake them.

OLIVER EVANS.

It would be unpardonable to omit noticing the steam engine of our ingenious countryman Jacob Perkins, which has excited so much interest in London. "Mr P.'s original idea of substituting pressure for surface, in generating steam (which appears to be the basis of his invention) if satisfactorily established, must certainly be considered as of the utmost importance, particularly in its first feature, *absolute safety.* From the mode of constructing the compound generator (of steam) as now adopted, it becomes a safety valve of itself: for the pressure is divided into so many compartments, that any one of them may explode with impunity, without even disturbing a brick of the furnace."* Mr. Perkins says "the piston was 8 inches in diameter, with a 20 inch stroke engine, a good 70 horse power, and consuming but one fourth of the coal of a condensing engine. The weight on the end of the lever was 300*lbs.* To prove the safety of the engine, he says, he has worked it under a pressure of 1400*lbs.* to the square inch, or at 100 atmospheres, and cut off the steam at one twelfth of the stroke. The usual pressure is 800*lbs.* per inch, cutting off at one eighth, and letting the steam expand to below 100*lbs.* per inch. He lets off at the dead point, at one flash." As this engine has not yet been introduced into practice by any one except the inventor, those who are desirous of a more full account of it are referred to the Franklin Journal, Vol. III. pp. 354, 407; to Galloway on Steam Engines, p. 185; Silliman's Journal, Vol. VII. The two last contain plates of the engine, and in Silliman is an account of the application of Mr. P.'s invention to engines of the old construction.

* Remarks of the editor of the London Journal of Arts.

STEAM-BOAT.

The subject of steam-boats has already been so amply treated in a separate chapter of our article Shipbuilding, in p. 244* of this volume, that very little remains to be done under the present head.

The action of impelling boats by mechanical power was suggested and put in motion more than three centuries ago;† but the proposal to employ steam as the first mover of vessels was first made by Mr. Jonathan Hulls in the year 1736, as we have already stated in the article Shipbuilding. The contrivance by which he proposed to produce this effect is shown in Plate DX. Fig. 1, which the author describes in the following words.

"Whereas several persons concerned in navigation, have desired some account of my invention for carrying ships out of and into harbours, ports and rivers, when they have not a fair wind;

But I could not fully describe this *machine*, without writing a small treatise of the same, in which I shall endeavour to demonstrate the possibility and probability of the matter undertaken.

There is one great hardship lies too commonly upon those who propose to advance some new, though useful, scheme for the public benefit; the world abounding more in rash censure than in a candid and unprejudiced estimation of things, if a person does not answer their expectation in every point; instead of friendly treatment for his good intentions, he too often meets with ridicule and contempt.

But I hope that this will not be my case; but that they will form a judgment of my present undertaking only from trial. If it should be said, that I have filled this tract with things that are foreign to the matter proposed, I answer, there is nothing in it but what is necessary to be understood by those that desire to know the nature of that machine which I now offer to the world: *and I hope that, through the blessing of God, it may prove serviceable to my country*.

In some convenient part of the tow-boat, there is placed a vessel about two-thirds full of water, with the top close shut. This vessel being kept boiling, rarifies the water into steam. This steam being conveyed through a large pipe into a cylindrical vessel, and there condensed, makes a vacuum, which causes the weight of the atmosphere to press on this vessel, and so presses down a piston that is fitted into the cylindrical vessel, in the same manner as in Mr. Newcomen's engine, with which he raises the water by fire.

In Plate DX. Fig. 2, *P* is a pipe coming from the furnace to the cylinder. *Q* the cylinder wherein the steam is condensed. *R* the valve that stops the steam from coming into the cylinder, whilst the steam within the same is condensed. *S* the pipe to convey the condensing water into the cylinder. *T* a cock to let in the condensing water when the cylinder is full of steam and the valve *p* is shut. *U* a rope fixed to the piston that slides up and down the cylinder. *Note.*—This rope *U*, is the same rope that goes round the wheel *D* in the machine, fig. 1.

It hath been already demonstrated, that a vessel of 30 inches diameter, which is but two foot and a half, when the air is driven out, the atmosphere will press on it to the weight of 4 tons 16 hundred and upwards. When proper instruments for this work are applied to it, it must drive a vessel with a great force.

Note.—The bigness of the machines may be proportioned to the work that is to be performed by them; but if such a force as is applied in this first essay, be not sufficient for any purpose that may be required, there is room to make such addition as will move an immense weight with tolerable swiftness.

It is my opinion, it will not be found practicable to place the machine here recommended, in the vessel itself that is to be taken in or out of the port, &c. but rather in a separate vessel, for these reasons: 1. This machine may be thought cumbersome, and to take up too much room in a vessel laden with goods, provisions, &c. 2. If this machine is put in a separate vessel, this vessel may lie at any port, &c. to be ready on all occasions. 3. A vessel of a small burthen will be sufficient to carry the machine to take out a large one. 4. A vessel will serve for this purpose for many years, after she is thrown off, and not safe to be taken far abroad.

The Explanation of the Machine. (See Plate DX. Fig. 2.)

A, Represents the chimney coming from the furnace.

B, The tow-boat.

C C, Two pieces of timber, framed together, to carry the machine.

D a, *D* and *D b*, are three wheels on one axis to receive the ropes, *M F b* and *F a*.

H a and *H b* are two wheels on the same axis with the fans *I I I I I*, and move alternately in such a manner, that when the wheels, *Da*, *D* and *Db* move backward or forward, they keep the fans *I I I I I* in a direct motion.

Fb is a rope going from *Hb* to *Db*, that when the wheels *Da*, *D* and *Db* move forward, moves the wheel *Hb* forwards, which brings the fans forward with it.

Fa is a rope going from the wheel *Ha* to the wheel *Da*, that when the wheels *Da*, *D* and *Db* move forward, the wheel *Ha* draws the rope *F*, and raises the weight *G*, at the same time as the wheel *Hb* brings the fans forward.

When the weight *G* is so raised, while the wheels *Da*, *D* and *Db* are moving backward, the rope *Fa* gives way, and the power of the weight *G* brings the wheel *Ha* forward, and the fans with it, so that the fans always keep going forward, notwithstanding the wheels *Da*, *D* and *Db* move backwards and forwards, as the piston moves up and down in the cylinder.

LL, are teeth for a catch to drop in from the axis, and are so contrived, that they catch in an alternate manner, to cause the fans to move always forward, for the wheel *Ha* by the power of the weight *G*, is performing its office, while the other wheel *Hb* goes back, in order to fetch another stroke.

Note.—The weight *G* must contain but half the weight of pillar of air pressing on the piston, because the weight *G* is raised at the same time as the wheel *Hb* performs its office, so that it is in effect two ma-

* See also Navigation, Inland, Vol. XIV p. 416.

† See Robertus Valturius *De Re Militari*. Verona, 1472.

chines, acting alternately by the weight of one pillar of air of such a diameter as the diameter of the *cylinder* is.

If it should be said that this is not a new invention, because I make use of the same power to drive my machine that others have made use of to drive theirs for other purposes. I answer, the application of this power is no more than the application of any common or known instrument used in mechanism, for new invented purposes.

Answers to some Queries that have been made, concerning the Possibility and Usefulness of this undertaking.

Query I.—*Is it possible to fix instruments of sufficient Strength to move so prodigious a Weight as may be contained in a very large Vessel?*

"*Answer.*—All mechanics will allow it is possible to make a machine to move an immense weight, if there is force enough to drive the same; for every member must be made in a proportionable strength to the intended work, and properly braced with laces of iron, &c. so that no part can give way or break. If the braces, &c. necessary for this work, had been put in the draught, it would have been so much crowded with lines, that the main instruments could not be so well perceived.

Query II.—*Will not the force of the waves break any instrument to pieces that is placed to move in the water?*

Answer.—1*st*, It cannot be supposed that this machine will be used in a storm or tempest at sea, when the waves are very raging; for if a merchant lieth in harbour, &c. he would not choose to put out to sea in a storm if it were possible to get out, but rather stay until it abated.

2*dly*, When the wind comes a-head of the tow-boat, the fans will be protected by it from the violence of the waves; and when the wind comes sideways, the waves will come edgeways of the fans, and therefore strike them with the less force.

3*dly*, There may be pieces of timber laid to swim on the surface of the water on each side of the fans, and so contrived as they shall not touch them, which will protect them from the force of the waves.

Up inland rivers, where the bottom can possibly be reached, the fans may be taken out, and cranks placed at the hindmost axis to strike a shaft to the bottom of the river, which will drive the vessel forward with the greater force.

Query III.—*It being a continual expense to keep this machine at work, will the expense be answered?*

Answer.—The work to be done by this machine will be upon particular occasions, when all other means yet found out are wholly insufficient. How often does a merchant wish that his ship were on the ocean, when, if he were there, the wind would serve tolerably well to carry him on his intended voyage, but does not serve, at the same time, to carry him out of the river, &c. he happens to be in, which a few hour's work of this machine would do. Besides, I know engines that are driven by the same power as this is, where materials for the purpose are dearer than in any navigable river in England; therefore, experience demonstrates, that the expense will be but a trifle to the value of the work performed by those sort of machines, which any person that knows the nature of those things may easily calculate.

Thus, I have endeavoured to give a clear and satisfactory account of my new invented machine, for carrying vessels out of and into any port, harbour, or river, against wind and tide, or in a calm; and I doubt not, but whoever shall give himself the trouble to peruse this essay, will be so candid as to excuse or overlook any imperfections in the diction or manner of writing, considering the hand it comes from; if what I have imagined, may only appear as plain to others as it has done to me, viz. that the scheme I now offer is practicable, and, if encouraged, will be useful. J. H."

The contrivance for converting the reciprocating motion of the piston into a rotatory motion, which does great credit to the ingenuity of Mr. Hulls, will be better understood from the enlarged drawing given in Fig. 3.

Although the invention of this steam-boat was thus distinctly laid before the public, yet it does not seem to have been put in practice till the year 1782, when the Marquis de Jouffroy constructed a steam-boat to ply on the Saone at Lyons. It was 140 feet long 15 feet wide, and drew $3\frac{1}{5}$ feet of water. He seems to have made several experiments with it, and it is said to have been in use fifteen months.*

In 1785, Mr. James Rumsey, of Virginia, and Mr. John Fitch of Philadelphia, made experiments on the propulsion of boats by steam, but though their labours were patronized by General Washington, and though they received patents from some of the States, yet no satisfactory results were obtained.

In the year 1785, Mr. Patrick Miller of Dalswinton, conceived the idea of propelling vessels by paddle wheels driven by men or horses. A twin vessel for this purpose was put on the stocks at Leith on the 7th January 1786, and launched on the 14th October 1787. He published an account of his plans in February 1787, and in that publication he stated that he "had reason to believe that the power of the steam-engine may be applied to work the wheels so as to give them a quicker motion, and to increase that of the ship, and that in the course of the summer of 1787 he intended to make the experiment." The suggestion of applying the steam-engine seems to have been make to Mr. Miller by Mr. Taylor, then living as tutor in his family, and this gentleman also recommended his school-fellow, Mr. William Symington of the Wanlockhead mines, who had recently contrived a method of applying the force of steam to wheel carriages, as a proper person to construct the steam-engine. In the spring of 1788, Mr. Symington began the steam-engine for Mr. Miller, and in October it was placed in a pleasure-boat in the lake of Dalswinton, and on the 14th October 1788, this boat was moved by steam in the presence of several spectators.† After several trials, however, it was found that the engine and wheel, which were of the same description as Hull's, required the aid of manual labour with a windlass. Another experiment was made with a larger engine (constructed at the Carron works,) on board a Gabard, but the machinery does not seem to have answered Mr. Miller's expectations, and all farther trials were discontinued.

* Dictionnaire de Physique, Art. *Chaloupe à Vapeur.*

† Scots Magazine, Nov. 1788.

In 1794 the Earl of Stanhope constructed a steam vessel with paddles below her quarters, but the result of the experiment was not satisfactory.

Lord Dundas, while governor of the Forth and Clyde navigation, employed Mr. Symington to construct a steam-vessel for that canal. An engine with a cylinder of 22 inches was accordingly made, and put on board a boat called the Charlotte Dundas. In March 1802, an experiment was made in presence of Lord Dundas, and his son-in-law, the present Mr. Spiers of Elderslie, and other gentlemen. This steam-boat towed two loaded sloops, the Active and Euphemia, of 70 tons burden each, from Lock No. 20 to Port Dundas, a distance of 19½ miles, in six hours, against a head wind. Some of the canal proprietors, however, were of opinion that the agitation of the water would destroy the banks of the canal, and the boat was laid up in a creek near Bainsford Bridge, where it lay as a wreck for many years.

Hitherto we may safely say that steam navigation had no real existence. Various individuals had proposed it as a national benefit, while others, supported by capital and influence, had entirely failed in all their attempts to reduce their plans to practice. In this state of things Mr. Henry Bell, a house carpenter in Glasgow, who had retired from his profession to the baths of Helensburgh on the Clyde about 1808, after making several experiments on the propulsion of boats by steam, and overcome some of the obstacles which at first beset his progress, employed Messrs. Wood and Co. of Port Glasgow to construct a boat for him on a particular plan. This boat had a 40 feet keel, and was 10½ feet on the beam, having a paddle wheel on each side. Mr. Bell made the steam-engine himself, and having completed his steam-boat in 1811, he gave it the name of the Comet, by which that year was distinguished. In January 1812 this boat began to ply on the Clyde between Glasgow and Greenock, and though the engine was only a three horse power, yet the boat went against a head wind at the rate of five miles an hour, and by merely increasing the power of the engine, her rate was increased to seven miles an hour. It appears from a letter addressed to Mr. Cleland by Mr. James Cooke, steam-engine maker, "that there was very little difference in the principle or construction of the impelling machinery of steam-boats in general use at present (April 4, 1825,) from that applied by Mr. Henry Bell in his steam-boat Comet, erected by him in 1811 or 1812. * * * The best possible proof," he continues, "that I can adduce in support of this observation, is the Glasgow steam-boat, built by Mr. Bell's direction in 1812 or 1813. The engine and impelling machinery were made and put into the vessel by me in 1813 or 1814. The vessel was, I believe, lengthened a little since, to give accommodation; the engine and machinery are still the same, and there are not many boats on the river at this day, that exceed her far in point of speed in still water. I do not recollect now what kind of speed the *Comet* went at, but if it was slow, I am inclined to think the cause of that was the want of a proper proportion betwixt the size of the vessel, and the power of the engine and impelling machinery, and not owing to any defect in the principle or construction of the machinery, those being nearly the same then as at this day."

But though Mr. H. Bell was undoubtedly the first person who introduced steam navigation into Great Britain, we must in justice to our American brethren admit, that this did not take place till four years after steam navigation had been introduced into America. In the month of October 1807, Mr. Robert Fulton of New York launched a steam-boat, which soon after plied with perfect success between New York and Albany, a distance of 160 miles. It is no doubt true that Mr. Fulton, when in England, derived great information from Mr. Symington, and afterwards received plans from Mr. Henry Bell, but this can never diminish his merit, or deprive him of the high honour of being the first individual who saw the vast importance of steam navigation to his country, and who collected all the information which he could procure, and, aided by his own original powers, at last triumphed over every difficulty, by constructing the first steam vessel that sailed upon the deep. Fulton was honoured and rewarded by a grateful country; but Henry Bell, a subject of Great Britain, the land ever famed for its science and its arts, and still the mistress of the ocean—has been allowed to spend his old age unhonoured and unrewarded.*

The history of steam navigation in America and in England has been so fully detailed in our article SHIPBUILDING, that it is unnecessary to pursue it any farther at present. The steam-boat has crossed the Atlantic, and has forced its way even to our territories in the East, where its utility has been recognised in the enterprises both of peace and of war.

The following table given by Captain Ross will convey an idea of the comparative lengths of voyages made in steam boats and sailing vessels.

	Steam Vessels.	Sailing Vessels.	Distance.
From Holyhead to Dublin,	8 hrs	70 hrs	55 miles.
Portpatrick to Donaghadee,	3	8	19½
† London to Leith,	55	5 days	429

Harwich to Helvoetsluys,	13	28	90

Having thus given a general and brief sketch of the progress of steam navigation, we shall proceed to describe the construction of a steam ship, and of the engine by which it is propelled.

The external form of a steam boat is shown in Plate DX. Fig. 4; and Fig. 5 represents the section of the two engines in the Royal George steam ship, as executed by Mr. Gutzmer, civil engineer, Edinburgh. At the two extremities of the two horizontal axles, A P, A′ P′, passing across the steam boat, are fixed the paddle wheels, one of which is shown at W W. The cylinders of the engines are placed behind the steam chests F, F′, and by the alternate ascent and descent of the piston rods B B, attached to the cranks C C′, a rotatory motion is communicated to the horizontal axles A P, A′ P′, and consequently to the paddles W W, which are fixed to them. The cranks which work the steam valves are shown at K K′. The air pump E is wrought by the crank D, which is driven by the inner branch H of each of the cranks. The boiler G G extends quite across the ship. The top frame *i i i i* of the engine, and the machinery are supported by the pillars *h*, *h*, *h*, *h*. The sides of the ship are shown at *l*, *l*, *l*, *l*, the deck at *m*, *m*, *m*, *m*, and the funnel at *k*.

As the object of the preceding figure is principally to convey an idea of the manner in which the steam engines are arranged on board of a steam-boat, we must refer to Fig. 6 for a distinct view in isometrical perspective of one of the engines for a boat, as arranged by Boulton and Watt. This arrangement, however, was adopted by Boulton and Watt, in common with others, from the engines erected on board the Clyde steam-boats. A section of a steam boat engine, but not exactly the same as that shown in Fig. 5, is shown in Fig. 7, and as we have put the same letters of reference to both, we shall describe them together, so as to give a perfect idea of the construction of the most approved steam-boat engines. The steam from the boiler is introduced into the top or bottom of the cylinder A by the steam pipe S S, after passing through the slide valve already described in p. 423. When it has acted upon the piston, it passes from the slide valve to the condenser B, where it is condensed into water by a rose jet in constant play. The air pump shown at C receives the condensed water from B, and forces the air and water into the cistern D, from which it flows out by a pipe. The reciprocating motion of the piston is conveyed to the crank by means of the beams or levers, one of which is shown at E F moving round G as an axis. These beams are connected with the T-piece L L, or cross head of the piston, by the side rods *m n o p*, forming part of the parallel motion, the guiding bars of which are M N, M′ N′. The working end of the lever E is united with the crank *i* H *i′* by the connecting rod H H. The air pump C is also wrought by side rods *c c* connected with the beams E F, and the hot water pump from the same T-piece or cross head. The slide valve is on Murdoch's plan, and is moved by a wheel on the shaft I of the crank, with a sliding frame P, and it may also be moved by hand by means of the lever T, the slide rod being moved by slings from the arm R. The steam passes into the condenser by the valve O, when the engine is set to work, and the air and water are driven into the cistern D at the discharge valve.

Two of these engines are generally placed on board every steam boat, a passage being left between them, and space being reserved for working the fires between the cylinder and the boiler. The coals are kept in iron tanks in the engine room.

The weight of an engine of this kind of 40 horse power, with suitable duplicate parts, water, &c. is about 100 tons.

The steam-engine of Mr. Gurney, as applied to steam-boats, is so very unlike those in common use, that we have given a representation of it in Fig. 7, from the engraving published by Captain Ross. The figure represents it as placed between the two decks of a vessel. Its boilers are exactly similar to those already described. (See p. 422, and Plate DIX. Fig. 14). The right hand boiler and fire place is shown open with the flame acting upon one of the tubes of its boiler, while the left hand boiler, represented shut, is shown with a case *g*, as it appears when in use. In the open boiler the direction taken by the flame to the chimney pipe or flue *s*, is pointed out by arrows. The flue *s* is common to the two boilers. The ash pit is shown at *d*, and *v* is the bridge for directing the passage of the flame. The extremities of the chambers which receive the ends of all the bent tubes that form the boiler, are shown at *c*, *c*, the separators at *a*, *a*, with their safety valves *b*, *b*, and guage cocks *e*, *e*, formerly described.

The engine has neither beam nor parallel motion. The cylinders *h*, *k*, are suspended like guns on trunnions at *p*, so that they can vibrate up and down. The steam is brought from the separators by pipes in the direction *w*, *w*, which introduce the steam through the trunnions. The opening and shutting of the valves is effected by a series of levers *g*, *r*, which act like hand gear. The piston rod of each cylinder is attached to cranks *m*, *n*, rising from the main shaft *o*, which carries the paddles, and are placed at right angles to each other, that when the one is in the position of producing a maximum force, the other is in the position of producing no effect at all. The main shaft *o*, the trunnions of the cylinders, and the working parts of the machinery, are supported on a frame work marked *i i i*, *u u u*.

Mr. Gurney is said by Captain Ross to have succeeded in contriving a modification of the centrifugal blast, as a substitute for the chimney, by which a current of air is diffused below the whole furnace over a large body and surface of fire, at a very low and constant pressure, sufficient merely for the perfect ignition of every part of the fuel. In this way the smoke is nearly consumed, the awkward funnel is rendered unnecessary, and the fuel is economised.

Mr. Gurney has added a small separate cylinder for working the supply pump, and also the blower. The price of a boat engine of 10 horse power, with one cylinder, is £400, and £100 for collateral expenses, such as paddles, wheels, shaft, fixing, &c. For higher or lower powers £30 must be added for every horse power. Captain Ross states, that, though Mr. Gurney's engine has not made its way in this country, yet it has in France. He ascribes this to its never having had a fair trial in England, in consequence of the inventor not having capital to bring it forward against the opinion of those who have an interest in keeping up the low pressure engine, which is the most profitable to the manufacturer.

The following table has been given by Captain Ross, as calculated to show the crews which are proper for steam vessels employed in conveying goods and passengers, and which each should be obliged to have on board.

Table of the Crews of Steam-Boats.

Class.	Tonnage.	Horse Power Engines.	Captain.	Mate.	Pilot.	Servants.	Female Servants.	Seamen.	Engineers.	Stokers.	Coal Trimmers.	Carpenters.	Total.
1	1000	200	1	1	1	8	2	14	2	6	5	2	42
2	500	150	1	1	1	5	2	8	2	5	4	2	31
3	300	100	1	1	1	4	1	6	2	4	3	1	24
4	200	60 to 80	1	1	1	3	1	4	2	2	2	1	18
5	100	30 to 50	1	0	1	2	0	3	2	2	1	1	13
6	boats	under 30	1	0	1	1	0	2	1	1	1	0	8

The following are the dimensions of the United Kingdom and Majestic, which are said to be the fastest packets that have yet been built.

Dimensions of the United Kingdom *Steam-Boat.*

Length on deck,	175 feet
Length of keel,	147
Extreme breadth,	45½
Depth of hold,	12
From the upper deck of keel,	18
Three feet of water fore and aft,	9½ *f* 10 *a*
Three feet of water with coals,	11 *f* 12½ *a*
Nature of engine,	low pressure
Power of engine,	200 horse power
Tons by law,	561 tons
Actual tonnage, besides engine,	350
Number of boilers,	160
Main mast,	81 6 1 8
Main top mast,	52 0 1 0
Fore mast,	76 0 1 8
Fore yard,	72 0 1 8
Fore top mast,	50 0 1 2
Mizen mast,	60 0 1 5
Quantity of coals stowed,	170 tons
Coals used per hour,	17 cwt.
Crew,	48
Velocity in miles per hour,	11
——— against a gale,	3

Dimensions of the Majestic *Steam-Boat.*

Length on deck,	144 feet.
Length of keel,	125
Extreme breadth,	39
Breadth between paddles,	22½
Depth of hold,	11
From upper deck of keel,	16
Three feet water fore and aft,	7 0*f* 8 0*a*
Three feet water with coals,	8 6*f* 9 9*a*
Nature of the engine,	low pressure.
Power of engine,	100 horse.
Tons by law,	270
Actual tonnage besides engines,	254
Number of births,	76
Main mast,	68 0 1 4
Main topmast,	45 0 0 9
Foremast,	60 0 1 4
Foreyard,	62 0 0 11
Fore topmast,	40 0 0 9
Mizen mast,	56 0 0 11
Quantity of coals stowed,	100 tons.
Coals used per hour,	15 cwt.
Crew,	31
Velocity in miles per hour,	10
——— against a gale,	3

Mr. Tredgold has given the following table of the dimensions of one of the best American steam-boats, and one of those lately constructed.

Dimensions of the North American *Steam-Boat*

Length of deck,	178 feet.
Depth of hold, from under side of beam to keel,	9
Breadth moulded,	28 feet.
Breadth extreme, above water,	58
Draught of water,	4½
Diameter of paddle wheels,	21
Breadth of paddle wheels,	13½
Depth of paddles,	2
Two engines, with cylinders, whose diameter is,	45 inches.
Length of stroke,	8 feet.
Number of strokes per minute,	22 to 26.

The average force of the steam is 9 inches of mercury above the atmosphere, and the maximum force, 14 inches. The distance from New-York to Albany is nearly 160 miles, and the voyage is performed, at an average, in 12 hours. The boilers are placed before, and the machinery abaft the paddle wheels. The two engines consume two cords of wood in an hour and 25 cords of wood during the above voyage. A cord of wood weighs about 3826 lbs. and the ratio of coal to wood is about 22 to 26.6, so that the equivalent quantity of coal per hour would be 16½ cwt. nearly.

In our article Shipbuilding, p. 247, 249, the reader will find very copious tables of the dimensions of the earlier steam-boats.

One of the most important desiderata in the construction of steam-vessels is the proper formation of the paddle wheels. Hitherto they have almost universally resembled common undershot wheels, in which the float boards are a continuation of the radii of the wheel, and though such wheels have theoretical disadvantages, yet their firmness and strength have given them a superiority over other contrivances, which, consisting of numerous parts and movable float-boards, are very liable to be broken.

There is, perhaps, no branch of the mechanical arts that has called forth so many inventions as the subject of paddle wheels, and yet, so far as we know, no modification of them has appeared which is likely to supersede those of the common form.

One of the latest and most ingenious of these is the invention of Mr. John Oldham, engineer to the bank of Ireland. By a simple and elegant mechanism the float-boards revolve on axes, independent of the axis of the wheel. and each float-board revolves once, during every two revolutions of the wheel, and in an opposite direction.

The following account of the principal of these paddle wheels is given by Dr. Lardner, who has instituted experiments with them, compared with the common wheel, and has found the results to coincide satisfactorily with those which he has deduced from mathematical calculation:—

"The consequence of the combination of the motions of the paddle boards and the wheel is, that the edge of every paddle board is always presented to the highest point of the wheel, as shown in Plate DX. Fig. 9. The entire action of each board, perpendicular to its surface, being revolved into two actions, one horizontal and the other vertical, the proportions, quantities, and directions of these actions will be seen at once, by observing the sides of the several parallelograms in the figure and the directions of the arrows. One peculiarity which this presents, and in which it differs most strikingly from other wheels, is, that all the horizontal arrows point in the same direction, indicating that all the horizontal elements of the forces of the boards act in the same direction, and that they, therefore, can be made to propel without any back action whatever. It will also be observed, that the vertical elements, which, on the one side of the vertical diameter *lift*, and on the other side *depress*, are much smaller in proportion to the whole force than in the common wheels, see Fig. 10. and therefore the force expended without any useful effect is much less in proportion to the whole force in these than in the common wheel.

A wheel of this kind having no back action, might be totally immersed, and would still continue to propel. In consequence of the diminution of the lifting and depressing efforts, or what is the same, of the degree of the *feathering* principle with which it is endowed, its motions through the water is smooth, and attended with but little agitation, and is, therefore, the more effectual as an impellent power."

Among the ingenious contrivances for propelling steam-boats, we must mention that of Mr. Gladstone's of Castle Douglas, who has proposed to have two wheels on each side, with a chain of float boards between them, as shown in Hydrodynamics, Plate CCCXX. Fig. 6, float boards or paddles being substituted in place of the buckets C, F. The two wheels A, B, are of course placed so that the line joining them or the direction of the line of paddles is a little inclined to the horizon. Such a construction has great theoretical advantages; but the looseness of all the parts has, we believe, been the cause of its failure in practice.

A method of propelling steam-boats without wheels was proposed and carried into effect in 1820 by J. B. Fraser, Esq. and G. Lilly, Esq. who took out a patent for the invention. The method consists in forcing out from the stem of the boat a small jet of water by means of compressed air. M. Bernouilli was, we believe, the first who suggested the idea of propelling boats by this means. He proposed to fix on the boat an upright bent tube like the letter L, the vertical part having a sort of funnel top convenient for filling the tubes with water, which, descending through the horizontal part, and issuing at the middle of the stern, and below the surface of the water, propels the boat by the reaction of the effluent stream. Dr. Franklin* proposed an improvement upon this method, which consisted in adding another tube of the form L. "The two standing back to back, the forward one being worked as a pump, and working in the water at the head of the boat, would draw it forward while pushed in the same direction by the force of the stern. And after all, he adds, it should be calculated whether the labour of pumping would be less than that of rowing. *A fire engine might also in some cases be applied in this operation with advantage.*" Dr. Franklin next proceeds to show how the boat might be propelled by the use of air in place of water, and he suggests the use of an air vessel with proper valves to permit the force to continue while a fresh stroke is taken by the lever.

The apparatus described in Mr. Fraser and Mr. Lilley's patent consists of a cistern or condensing reservoir placed near the bow. From this cistern there descends a main tube, with a plug that may be opened and shut at pleasure. Two tubes, each of them having a plug, branch off from the main tube, and extend to a point rather nearer the bow than the centre of gravity of the vessel. From these two tubes the water issues in propelling the vessel. The main tube, however, continues to extend till it reaches a point about one-third of the length of the boat from the stern, and then divides into two tubes, which are bent back so as to open towards the bow of the vessel. The water is made to issue from these tubes in order to repel the vessel or give it stern way; other four tubes branch off from the main tube before the two first, two going to the bow and two to the stern of the vessel, and they are put at right angles to the keel, one of each pair being directed to one side, and the other to the opposite side of the vessel. The plugs of these tubes are united transversely, so that either pair being opened the water may issue near the bow on one side of the keel and near the stern on the opposite side of the keel for the purpose of turning the boat. A pump wrought either by men or by steam is then connected with one side of the condensing reservoir. A boat thus fitted up and wrought by two men, who pulled at separate levers in the same manner as in rowing. went at the rate of three miles in an hour, though the two apertures which discharged the water was only one-fourth of an inch in diameter each. A full account of this apparatus, with engravings, was given by the editor of this work in the *Edinburgh Philosophical Journal*, Vol. V. p. 120.

Many different contrivances have been invented, and some of them secured by patent, for rendering steam-boats fit for a tempestuous navigation. Messrs. Redhead and Parry have proposed to extend two horizontal channels through the whole length of the vessel, with apertures at the stern and the bow at which the water can enter and escape. The water rises nearly to the top of these channels, and two or more pair of paddle wheels are mounted, having their paddles immersed about one foot beneath the water in the channel. In very stormy weather the apertures of the channels may be closed by the shutters, and the water

* Memoirs of the Life and Writings of Benjamin Franklin, vol. vi. p. 451. Lond. 1819.

pumped out. In this condition the ship may be navigated by sails.

The fine American steam ship the *Savannah*, which crossed the Atlantic, and arrived at Liverpool on the 20th June 1827,* after a passage of 21 days, had its paddle wheels constructed so that they could be taken to pieces; and removed in bad weather, except two principal arms of each, which being of cast iron and firmly fastened, are placed in a horizontal position in high seas. The engines were in use during 18 days of the 21 that the passage lasted.

For farther information on the subject of steam navigation, see Jonathan Hulls's *Description of a new invented machine*, &c. 1737. Buchanan *on Steam Navigation*, Glasgow, 1816. Cleland's *Historical Account of the Steam Engine, and its application in Propelling Vessels*, 1825. *Memoire sur la Navigation a Vapeur*, par M. Seguin. Aimé Paris, 1828. Dr. Lardner's *Lectures on the Steam Engine*. London, 1828. And Dr. Brewster's Edition of *Ferguson's Lectures*, Vol. II, p. 112-117.

It is only of late that the world has been informed of the first attempt made to use the powerful agency of steam in propelling vessels. Blasco de Garay, a sea captain, in the presence of Charles the Fifth of Spain and sundry officers of state, in the year 1543, made an experiment upon a ship of 200 tons at Barcelona with an engine, all of which was not exposed, but it was observed to consist in part of a large caldron or vessel of boiling water, and a movable wheel attached to each side of the ship. The emperor, prince and the other spectators applauded the engine, and especially the expertness with which the ship could be tacked: and Garay was munificently rewarded. The exhibition being finished, he took the engine from the ship, and having deposited the woodwork in the arsenal of Barcelona, kept the rest himself.† This account is given in a note to the first volume of a work lately published in Spain, containing original papers relating to the voyage of Columbus. It was communicated to the author by Thomas Gonzales, dated Samancas, August 27, 1825, and said to have been taken from the Royal Archives of Samancas for 1543.

In page 258 some account was given of John Fitch's steam-boat, which was built in Philadelphia, and made several experimental excursions on the Delaware. In plate DX. Fig. 2, its form may be seen. The following account of it is given by the unfortunate inventor in the Columbian (Philadelphia) Magazine, Vol. I. for December 1786. "The cylinder is to be horizontal, and the steam to work with equal force at each end. The mode by which we obtain what I term a vacuum, is, it is believed, entirely new, as is also the method of letting the water into it, and throwing it off against the atmosphere without any friction. It is expected that the cylinder, which is of 12 inches diameter, will move a clear force of 11 or 12 cwt. after the frictions are deducted; this force is to be directed against a wheel of 18 inches diameter. The piston is to move about three feet, and each vibration of it gives the axis about forty evolutions. Each evolution of the axis moves twelve oars or paddles $5\frac{1}{2}$ feet; they work perpendicularly, and are represented by the strokes of a paddle of a canoe. As six of the paddles are raised from the water, six more are entered, and the two sets of paddles make their strokes of about 11 feet in each evolution. The crank of the axis acts upon the paddles, about one third of their length from their lower ends, on which part of the oar the whole force of the axis is applied. The engine is placed in the bottom of the boat, about one third from the stern, and both the action and reaction turn the wheel the same way."

Fitch gives a particular account of the progress of his operations in steam, from the first time that the thought occurred to him of using it, to the completion of the boat, so far as to make numerous experiments on the Delaware: the subsequent alterations made in it, and the final abandonment of the scheme by the original subscribers. This account shows him to have been a strong minded, but unlettered man, with a perseverance almost unexampled, and a determination to let no difficulty in the execution of his plan prevent him from endeavouring to bring it to perfection, so long as the share-holders furnished the means of defraying the experiments. As stated, p. 258, they refused to advance more funds. This they did after interfering with his views, and attempting expensive plans of improvements, which failed of success. The conviction of Fitch, however, respecting the power of steam continued firm; and in June 1792, when the boat was laid up, he addressed a letter to Mr. Rittenhouse, one of the share-holders, on the subject, in which he says "it would be much easier to carry a first-rate man of war by steam, than a boat, as we would not be cramped for room, nor would the weight of machinery be felt. *This, Sir, will be the mode of crossing the Atlantic in time*, whether I bring it to perfection or not, for packets and armed vessels. I mean to make use of wind when we have it, and in a calm, to pursue the voyage at the rate of seven or eight miles an hour." He further suggests the use of steam to conquer the cruisers of Barbary, by which several American vessels had been taken about that time. He says, "a six foot cylinder could discharge a column of water from the round top 40 or 50 yards, and throw a man off his feet, and wet their arms and ammunition." He complains of his poverty, and to raise funds, he urges Mr. Rittenhouse to buy his land in Kentucky, that he "might have the honour of enabling him to complete the great undertaking. His enthusiasm on the subject never diminished one moment, and steam was the constant theme of his discourse, whenever he could prevail upon any one to listen to him. Upon one occasion he called upon a smith who had worked at his boat, and after dwelling for some time upon his favourite topic, concluded with these words: "Well, gentlemen, although I shall not live to see the time, you will, when steam-boats will be pre-

* This is an error: the voyage here referred to was made by the Savannah in 1819. It appears by reference to her Log-book that she left New York for Savannah on Sunday, March 28, 1819, and arrived there on Tuesday, April 6th. Left Savannah on Tuesday, May 25th, and came to anchor at Liverpool on Sunday, June 20th 1819, at 6 P.M. Friday, July 23d 1819, at 1 P.M., left Liverpool for St. Petersburgh, and on Thursday Sept. 9th at 4 P.M. moored off Cronstadt. Sunday October 16th, at 9 o'clock, left Cronstadt, and on Tuesday, 30th November, at 5 P. M. anchored off Savannah. On the 5th December she left Savannah for Washington, and arrived on the 14th, where she was sold.—Editor Am. Edition.

† North American Review for 1826, p. 489.

ferred to all other means of conveyance, and especially for passengers, and they will be particularly useful in the navigation of the river Mississippi." He then retired, when a person present observed, in a tone of deep sympathy, "Poor fellow, what a pity he is crazy."* The prediction of the benefits which this country would one day derive from steam navigation, are made in sesevera places in the course of his manuscripts left to the library company. The distress of mind, and mortification he suffered, from the failure of his protracted exertions, and his povery, were too much for him, and to drown his reflexions, he had recourse to the common, but deceptive remedy, strong drink, in which he indulged to excess, and retiring to Pittsburgh, he ended his days by plunging into the Alleghany.

James Rumsey was a native of Virginia, and resided at Shepard's Town. He proves by affidavit that he had conceived the idea of propelling a boat by steam in 1783, and actually made two experiments with a small one in the Potomac in December 1784, in the first of which she went three miles an hour against the current, and in the last her speed was increased to four miles. His plan was to admit water through a trunk on the kelson of the boat, and by means of steam to discharge it at the stern, calculating that the power of reaction would propel her forward. The boat however was not made practically useful. Leaving the United States to his opponent Fitch, he sailed for London, where he made another experiment on the Thames, but whether on his former principle, or on some other, is not known. His death put an end to his operations. A controversy was carried on between Fitch and Rumsey for the honour of the first discovery of the power of steam for navigation, and two pamphlets were published by them, in defence of their respective pretensions, in 1788.

But for one of those unfortunate accidents which so often totally defeat the best contrived plans, Mr. Evans would have had the satisfaction of seeing one of his steam engines propelling a boat in the Mississippi two years before steam boats were seen on the Hudson. In the year 1802, having informed gentlemen in Kentucky that he had his engine in motion, which he had long before invented for propelling boats and carriages, Captain James M'Keever, formerly of Philadelphia, and Mr. Louis Valcourt agreed to build a steam boat to ply between New Orleans and Natchez, and Mr. V. came to Philadelphia to order the engine. Two of Mr. Evans's workmen went with the engine to meet the boat at New Orleans, and set it up. She was of the burthen of 150 tons, and built in Kentucky. Soon after her arrival at New Orleans, she was sunk and destroyed during a hurricane. The engine was then applied to sawing timber, and when fairly in operation, the mill was destroyed by fire. Capt. M'Keever died in 1810, and the engine was then sold to press cotton, and was worked with success.†

From the report of the late Mr. Stackhouse, one of the engineers who was sent to put up Captain M'Keever's engine, it appears that "in twelve months and fifteen days, with three saws (but with power for four) he sawed 367,000 feet of boards and scantling; that nothing relating to the engine broke, or got out of order, so as to stop the mill one hour. They sawed by day only, and the three saws cut from 2,500 to 3,000 feet per day of twelve hours, with the consumption of about one and a half cords of wood per day. The engine was of 20 horse power; the cylinder was only nine inches diameter, and the stroke of the piston three feet, making thirty-six strokes per minute, and working without a condenser; the fire place was outside of the boiler.‡

In 1812 there were ten of Mr Evans's engines in use in different parts of the United States; ten were made, making, or engaged.§ After that time, several were erected in boats; but owing to the explosion of the Ætna at New York, in the year 1824, such a prejudice was created against them, that the proprietors were forced to take them out of all the boats plying on the North River and Delaware, and to substitute those on the low pressure principle, although fully as liable to explosion as the boilers of those on the high pressure principle.

In page 256 of the present volume, ample justice is done to Mr Fulton, to whom the United States and the whole world are under everlasting obligations, for showing the possibility of doing effectually, what had been only partially accomplished in Europe, in respect to the power of steam in navigating boats; no more need be said upon the present occasion on his great merits.

Mr Stevens, of Hoboken, New Jersey, had been for many years making experiments upon steam to no purpose, and at an immense expense; but it was not until the memorable year 1807 that he had been able, with the assistance of one of his sons, to set a boat in motion. Being prevented by the monopoly of Livingston and Fulton from sailing in the waters of New York, she was sent round to the Delaware, and plied in it for about two years.

Since that time the improvements in steam boats have gradually progressed, and there is now no question about the superiority of the speed of the American boats over those of Europe. The common rate of going, in the North River, of the boats built by Mr Robert L. Stevens, is $13\frac{1}{2}$ miles per hour. The noble boat, the President, Captain Bunker, plying between New York and Providence, through Long Island Sound, distance 200 miles, commonly performs that voyage in 16 hours. In page 257 of this volume, several facts on the subject of the rates of speed by the United States steam-boats are given. The two following instances were published in the newspapers in the month of April 1831.

The steam-boat De Witt Clinton, (of the North

§ Archives of Useful Knowledge, vol. ii. p. 363, in which the places of their erection, and the purposes of their use are given. On the western waters, from recent private information from an authentic source, it appears "that the proportion of low to high pressure engines, both for large and small boats, is as 1 to 8, many of them over 400 tons burthen. The simple and convenient form of the cylindrical boiler for being kept clean, and the absence of valves working in water, which are the accompaniments of low pressure engines, render this kind of engine peculiarly adapted to the muddy and sandy waters of the Mississippi. Several fine large boats have come round from the Atlantic ports with low pressure engines, but have not been able to compete with the western boats, until the boilers were changed."

River Line,) left Albany at 4 minutes past 4 o'clock, Tuesday afternoon, April 1831, and arrived at the landing place in New York, at the foot of Barclay street, at 12 minutes before 3 o'clock Wednesday morning, making the entire passage, including the landings at Hudson, Catskill, Rhinebeck, Hyde Park, Poughkeepsie, Newburgh, West Point, and Caldwell's, in 10 hours and 44 minutes.

The steam boat Highlander left Wheeling, on the Ohio, at 12 o'clock, on the 12th of April 1831, and returned in less than 18 days. The distance to St. Louis is 1200 miles, 200 of which up the Mississippi, a river of very rapid current.

A citizen of the United States set the first example of crossing the Atlantic in a steam ship. Captain Moses Rodgers, in the ship Savannah, sailed from Savannah, in Georgia, in May 1819, to Liverpool, and thence to Russia, and returned to the United States in November of the same year: and from 1819 to 1821, the steam ship Robert Fulton plied between New York and New Orleans, calling at Havanna. The English ship Enterprise has since that time performed a voyage to India in 118 days; and steam boats are in operation between the various British ports in India, and thence to the Cape of Good Hope.

On the Explosion and Rupture of Steam Boilers.

The remark, that it is the lot of mortality to have good united to evil, has been made a thousand times, and applies with peculiar force to the case of Steam Engines. A great drawback upon the profit and convenience derived from the powerful agency of steam, and from the satisfaction consequent on the facilities and rapidity of travelling afforded by steam-boats, and the comforts enjoyed on board of them, is the fear of the explosion of their boilers, or the rupture of their steam tubes. It has been thought proper therefore on the present occasion to collect all the information possible on the subject, to examine and detail the circumstances under which they have occurred, to state the causes of the accidents, and to point out the means most likely to prevent their occurrence. The causes which are known to have produced these explosions and ruptures, are as follow:

1. The continued application of heat to a boiler, while any part of it is uncovered with water, or in which it is expended.

2. The steam being prevented from passing off, owing to, 1. The rusting of the safety valve. 2. Its adhesion to its seat. 3. Stopping the steam pipe by the valve, owing to the improper form of the pipe. 4. Overloading the safety valve, or of fastening it down, so as to increase the power of the steam beyond the maximum point which the force of cohesion in the metal of the boiler would bear, or while the engine was stopped from working. Small size of the valve.

3. Want of proper precautions to strengthen the boiler, when first made.

4. The use of internal flues in boilers.

5. The use of improper metal in the construction of the boiler.

6. The use of metals for boilers, of different expansive powers.

7. Weakness of the boilers from long use, or unequal thickness in the metal, and raising the steam to a height beyond its strength.

8. Faulty form of the boiler.

9. A collection of earthy or saline sediments on the bottom of the boiler.

10. The sudden increase of the pressure of steam on a boiler.

1. *Loss of water in the boilers.*

The cases embraced under the first cause are, the loss of water in or around the boiler or boilers, from, a. leaks; b. neglect of a supply of it; c. the heeling of the vessel from the concourse of passengers on one side, thus forcing the water from one or more of the boilers, when several are in use ; or causing the boat to heel so much to one side as to render the guage cocks useless; d. obstructions in the pipe or pipes feeding one or more boilers.

It is believed that most of the explosions of steam boilers may be ascribed to the first cause, and its several modifications. The neglect to supply boilers when leaky, or to keep those filled which are sound, admits of no excuse : and misfortunes arising therefrom, to passengers on board of boats, affords as just and legitimate grounds for an action of damages, as those that occur in stage-coaches from racing, mismanagement, intemperance in the driver, or his wilful indifference in any way, to the safety of travellers.

The explosion in one of the high pressure boilers of the Union Rolling Mill at Pittsburgh, a few years since, can be ascribed only to this cause. There were three cylinder boilers, each of thirty inches diameter, one of which had been observed for some time to be getting red hot; but as the other two had supplied a sufficiency of steam for the works, it was disregarded until it exploded, and shooting through the air, at an angle of forty-five degrees with the horizon, fell into the river two hundred yards from the works.* The over heating of the exploded boiler cannot be ascribed to any other cause than the want of water in it. Boats on the western waters are particularly exposed to danger from this cause. Many of them have several boilers connected with one

* The steam was said to be on fire, but Dr. Jones justly attributes this appearance to the boiler being at one end heated to redness, and supposes that the meteor-like appearance which it exhibited, was owing to the rapid passage of the projected boiler through the air. To the eye, this, like the whirling of an ignited coal, would present a lengthened stream of light, and apparently justify the conclusion, that there was real combustion.—*Franklin Journal*, vol. ii.

another; when one of these boats leaves port with a full cargo of passengers, goods, and a supply of wood, she sinks deep in the stream, and the boilers are all surrounded with water to the proper height. In the course of her voyage wood is consumed, passengers and goods are landed, the forward portion of the vessel rises a little from the weight of wood being removed, and when a landing place is reached, all the passengers invariably rush to the side next the land, and thus cause the boat to heel, and the water to run out of the boilers on the opposite side. The same effect is produced by 400 or 500 passengers sometimes sitting on one side of the boat in summer, to avoid the sun. In the meantime the fire is kept up, the empty boiler becomes red hot, and when the boat recovers her trim, the heated water rushes into the empty boilers, highly expansive steam is instantly generated, and when the throttle valve, or safety valve is opened, the water mounts up with the steam, and filling the boiler, presses on the weakened metal beyond its power of cohesion; an explosion therefore must take place. The awful disaster on board the Helen M'Gregor, March 1830, is a case in point. The explosion took place at Memphis in Tennessee. The engine was on the high pressure principle. She had six or eight boilers, and was full of passengers; nearly all of whom, when at the landing, came to the side near the shore, and of course caused her to heel greatly, and to drive the water from the boilers on the other side into those next the land. The fire was kept up during her stoppage, and thus must have rendered the empty boiler red hot. *The explosion instantly followed the opening of the throttle valve to set the engine in motion.* Between 60 and 80 persons were killed, scalded and wounded, and the boat was reduced to a mere wreck. The boat Chief Justice Marshall was another instance of the same kind: "the main internal flue gave way when the engine was set in motion after a stoppage at Newburgh, North River; the safety valve was either open, or had just been closed; one of the persons on board remarked a peculiar shrillness in the sound of the escaping steam, that can only be ascribed to its being intensely heated, without having a corresponding density. Another observed that it had a violet hue, which may perhaps be explained by supposing it to have been heated until it would have been luminous at night. In opposition to the opinion that the water had fallen too low, and left the flues bare, it was stated by the captain, that the guage cocks had been tried, but on examination it was found that they were situated on the side of the boiler nearest the landing; and hence the influx of passengers to that side changed the level of the boat so much as to render the guage cocks, when so situated, useless as a test of safety. It is also possible that the fireman, who was a new hand, and by no means skilful, may have mistaken the water of condensation in the tube for that coming from the boiler. This last mistake is one that ought to be carefully guarded against by leaving the cock open several seconds."*

It would appear from the following statement, that besides the probable over heating of the boiler, the steam had been permitted to collect in quantity beyond the cohesive powers of the boiler. The editor of the New York American vouches for the respectability of the writer.

From the New York American, April 24, 1830.

Mr. Editor,—I perceive the captain of the Chief Justice Marshall says, that the steam was blowing off continually while landing. I doubt the correctness of this statement. My own very strong impression is, that no steam was going off while she was approaching the dock, nor while she was taking in the Newburgh passengers, of whom I was one, and that it was not permitted to escape at all, till within about three minutes of the explosion. For three or five minutes before this took place, I was standing at the door of the captain's office; and having nothing else to do, directed my whole attention to the steam; it was going off at that time, but so very slowly as to make but a slight murmuring sound. This continued three or four minutes, and was exchanged for the shrillest and most piercing whistle I ever heard; so that I immediately made the reflection (whether correct or not I do not know), "The steam is excessively high!" Still it appeared to me that very little steam was escaping, and as if it passed through an exceedingly small aperture. This sound continued a few seconds; it suddenly ceased, and, almost simultaneously, the boiler exploded! My own opinion is, that the steam was suffered to accumulate in the boiler in a very improper manner; and, as all the disasters of this kind have happened while boats have been lying at or leaving the dock, is it not fair to conclude, that it is owing to this cause—the improper accumulation of steam in the boilers? Why the steam is kept there pent up, I know not; but it seems to me it cannot be done without danger. No law on this subject would probably contribute more to the safety of passengers than one which should provide, that the moment the steam ceased to be employed by the piston, it should be let off in the same proportion at the safety-valve.

A PASSENGER.

As the captain positively states that the safety valve was open, he must be believed: the doubt expressed by "a passenger," as to the fact, except until about three minutes of the explosion. may be explained by the facts discovered by Mr Perkins, viz: 1. That "steam highly surcharged with heat, when rushing from the safety valve, or any other aperture, may be known by its perfect invisibility, even in the coldest day: it is, however, he says, condensible, as may be seen by holding any cold substance in its range." 2. "The whistling" mentioned is another proof of the highly heated steam in the boiler: for, Mr Perkins found by a truly important experiment, that steam highly heated, when issuing from a small aperture, produced such a noise.†

* Renwick on Steam Engines, p. 97.

† Mr Perkins "discovered that a steam generator at a certain temperature, although it had a crack in it, would not emit either water or steam. A friend ascribed it to the expansion of the metal closing the fissure. To remove every doubt, he drilled a small hole, one fourth of an inch in diameter, through the side of the generator: after getting up the steam to a proper temperature, he took out the plug, and although he was working the engine at 30 atmospheres, *nothing was seen or heard* to issue *from*

The fatal accident on board the Oliver Elsworth in March 1827, near Saybrook, when on her passage to New York, may be ascribed to the same cause. During a "heavy sea and high wind from the S. W., the boiler burst by collapsing the main flue, and forcing out the furnace head with a tremendous report, louder than the heaviest cannon." Mr. E. Hazard judiciously asks, "supposing the water to have been at its proper height in the boiler, may not the motion of the vessel from a head sea have left portions of the boiler exposed to the fire for a length of time sufficient to make them red hot?"

A boiler about eighteen feet long at Kensington, Philadelphia county, in which the water had been greatly, if not entirely expended, owing to the fire being kept up during the absence of the fireman at dinner, collapsed from the over heating of the return flue, which was reduced from one foot in diameter to two inches.

Stoppage of the Feed-pipe. The Etna. This was the second steam-boat in which an explosion took place in the United States. It happened in May 1824, between Washington in New Jersey and New York. The Etna had three boilers below deck, and on the high pressure principle, and all new. The feed pipe of the centre one was longer than the other two, and near its internal extremity was bent; a circumstance that favoured the deposition of the solid contents of the brackish water which had been used to supply them for some weeks, and which did not take place during the several years she had previously ran in the Delaware. Hence the supply of water was cut off from this boiler, which is known to have become red hot, and must have been nearly empty. It was observed too that just before the explosion the pressure was diminished from 150 lbs. to 50 lbs., owing no doubt to a sudden projection of a limited portion of the remaining water into the hot vapour, of which the heat of temperature became latent heat, and in this condition was less efficacious in producing pressure than it had been in the free state.

It was ascertained that at the time of the explosion, the engine was making only eighteen strokes per minute, and had often made twenty-two: the common rate of working was twenty strokes. The first joint of the boiler over the fire was torn off, and driven up through the wheel-house, not in the direction of the boiler, but at a considerable angle, breaking the arms of the wheel; the body split in a spiral form, one and a half turns, and was thrown up flat on the deck, with the exception of the back end, which retained its form from the strength derived from the cast iron head.

The explanation of the mode in which the explosions take place from the loss of water is as follows: In consequence of the continued application of fire, or of highly heated steam to the upper part of a boiler, when not covered with water, it becomes red hot,* the cohesive power of the metal is greatly weakened, or destroyed, technically "*nealed*," and may be easily broken with a slight force. A boiler thus weakened would be unable to resist the pressure of the highly heated and expansive steam produced from the continued fire under the above circumstances, and might burst before it was subjected to a pressure sufficient to raise the safety valve. This effect is more certainly produced by water coming in contact with the metal when in this heated state, an event which Mr. Perkins suggests may take place "by the weight being taken from the safety valve, or by a small rent occurring in the boiler owing to the pressure of the steam, when an explosion will be sure to follow." The water would also be forced up by the opening of the throttle or safety valve, as has already been mentioned; and in any of these cases, the water being relieved from the pressure of the steam on its surface, would rise with it in proportion to the rapidity and suddenness of its escape. Such instances have been noted above. Mr. Perkins states, that in the case of the English boat Graham, twenty pounds had been taken off the safety valve just before the explosion took place. Two explosions in cotton mills in France, which are quoted by Arago, and said by him "to appear so paradoxical as to excite a doubt," may be added to the above cases. While the steam engines were working very slowly, the safety valves opened, and the boilers burst; no doubt the water in both cases had descended too low, and the upper part of the metal had become red hot. In respect to one, it is stated that the workmen "supposed it to be almost void of steam." Another similar case occurred in a low pressure engine at Lyons, and is noticed by Arago. In all these, the steam must have received an excess of heat, without acquiring a proportionate elasticity: hence the engines worked more slowly than usual, but when the water rushed up, on the overheated metal, highly elastic steam was formed, and the mischief produced. The same effect may ensue from the at-

the plughole: he next lowered the temperature by shutting the damper and opening the furnace door; a *singing from the aperture was soon observable*, and *when a coal was held before it, rapid combustion ensued: nothing however was yet visible;* but as *the temperature decreased*, the *steam became more* and *more visible*, the noise at the same time increasing, until finally the *roar was tremendous*, and might have been heard at the distance of half a mile. The iron at the aperture was red hot." Mr P. gives this experiment to illustrate the *repellent power of heat*, and to prove that caloric is matter.—*Franklin Journal*, iii. p. 413.

* "Mr. Moil informed Mr. Perkins that on going to his boiler room, he observed a ladder, the foot of which rested on the top of his boiler, to be in flames. He instantly ascertained that the top of the boiler had become red hot. The fire was quenched, and upon examining the boiler when cold, he found very little water in it." *Franklin Jour.* iii. p. 420. "On board the Dublin and Liverpool steam boat, a piece of pine wood on the top of one of the boilers was burnt to a coal, although the engine was working with steam only a few pounds above the atmospheric pressure. The leaden joints of the steam pipe once melted, when the steam guage indicated only the pressure at which the engine was usually worked. In *both these cases the water was so* low in the boilers, that the heat was communicated to the steam through a portion of the boiler which had no water in contact with it, and which of course became red hot, while the steam could not part with its heat *downwards*, to the water."—E. Hazard, *Franklin Jour.* iii. p. 421. Several instances have occurred where there was sufficient time, by the rushing of the steam from a rent or fracture, for the bystanders to escape from the injury before the explosion took place. In one case the boiler was raised from its bed into the air, by the force of the steam issuing from the rent (upon the principle of the rocket) before the water had sufficiently expanded by the removal of the steam caused by the rent or fracture, to take up the heat of the boiler and the surcharged steam; when an explosion took place after the boiler had been raised many feet into the atmosphere, and it separated with a very great report, one part rising still higher, while the other was dashed with great force on the ground."—Perkins, *Franklin Jour.* vol. iii. p. 417.

tempt to remedy the neglect to supply the heated boilers with water, by pumping in cold water, until it rise to the level of the overheated and weakened part of the boiler. To this cause may have been owing the fatal explosion that took place on board the steam-boat Tricolor at Wheeling, on the 19th April 1831. A letter states "that she had been puffing off steam in the morning, until 9 o'clock, and that the explosion happened the instant the engine was started, and *cold* water was injected into the boiler." Upon examining ruptures in boilers, they have sometimes been found to follow the water line.

The interesting discovery of the want of proportion between the temperature and elasticity of steam is due to our countryman Perkins, whose experiments to prove it are given in the Franklin Journal, vol. iii. To this cause he ascribes the tremendous explosions that suddenly take place as well in low, as in high pressure boilers. These explosions having taken place when no apparent reason could be assigned for them, have been ascribed to the formation and inflammation of hydrogen gas in the boiler. But this opinion is contrary to true chemistry. On this subject professor Hare observes, that red hot iron may decompose the steam slowly, but it can do so only by absorbing oxygen, which must lessen the quantity of elastic matter in the boiler, and render the evolved hydrogen gas inert, as by itself it cannot explode.* Dr. Jones adds, that the hydrogen would be altogether incapable of producing an explosion without admitting atmospheric air, which air must find its way into a vessel filled with vapour in a state of tension, and exciting a pressure outwards much greater than that of the external air.†

Arago admits the possible formation of hydrogen gas from the contact of steam with metal heated to redness, mixed with steam; this gas will pass into the cylinder of the engine, and not being capable of condensation, will be thence expelled at a great expense of power. He can allude here only to condensing engines. Upon the supposition that the oxygen, an admixture of which with the hydrogen is necessary to produce an explosion, would be furnished by the atmospheric air in the water of the boiler, he answers, that this water is warm, and therefore contains but a small quantity of air; and this air, as fast as it is disengaged from the water, passes in a state of mixture with the steam into the engine. Farther, the oxygen of this air would combine with the heated metal more readily than that contained in the water would do; and thus, if hydrogen gas should be produced from the water, it would find nitrogen present with which to mix, but no oxygen.‡

In connexion with the subject of explosions referred to the overheating of the boiler, through the deficiency of water, we may mention a paper in a late number of the American Journal of Science (vol. XIX. p. 294), by Mr. Walter R. Johnson, in which he details several series of experiments undertaken expressly to ascertain what effect might be produced by a known quantity of metal heated to redness, and then plunged below the surface of water at boiling temperature. As the experiments were made with all due precautions to avoid loss of temperature by the water during the process, to determine the weight of steam produced, and its relation to that of the metal employed, and to expend the whole of the surplus heat of the latter, above boiling temperature, solely in giving the elastic form, there cannot be a doubt that they furnish very accurate practical data by which to judge of the effect of an overheated boiler, when suddenly supplied with hot water.

These experiments demonstrate, that at a *dull red heat in day light*, each pound of wrought iron is capable of generating one ninth of a pound of steam; in other words, that nine pounds of metal in that state, are sufficient to give the elastic form to one pound of boiling water under atmospheric pressure. Of cast iron, it appears that $8\frac{231}{1000}$ pounds are adequate to the same effect.

The lower arch only of a cylindrical boiler 20 feet long, 30 inches in diameter, made of $\frac{1}{4}$ inch rolled iron, would, together with a returning flue one foot in diameter, and of the same thickness, weigh not far from 1500 pounds, and would consequently, if made red hot, be capable of producing more than 160 pounds of steam, with a bulk of upwards of 4400 cubic feet—more than fifty times the contents of such a boiler—and all this tremendous energy would be developed in a time not exceeding thirty seconds!

Mr. Thomas Earl has also given a neat demonstration on this subject, in the Franklin Journal, vol. vii. p. 156, and in accordance with the above theory.

2. *Obstructions to the Escape of Steam.*

The obstruction to the escape of the steam from the causes noted, are so intimately connected with the safety of the boiler, as scarcely to require any remarks to enforce the propriety of preventing it from taking place, by constant attention to the safety-valve. The only instance of the adhesion of the safety valve to its seat, that has been recorded in the United States, is one that is said to have taken place in the North River, New York, and of which the following account has been published by Mr. J. B. Calhoun.

"In the summer of 1829 I was engineer on board the steam-boat Legislator, of Hudson; and noticing that the engine was working faster than common, and not seeing any steam flow as usual from the safety valve, I went to the fire-room, and was told by the fireman that he had on twenty-one inches of steam, and that the *steam-guage* was up against the *boiler-deck*. As the safety-valve was loaded to carry only sixteen inches, I became alarmed, and taking hold of a cord that ran over a pulley, and was attached to the lever of the safety-valve, I attempted to raise the valve, but could not; on going to the top of the boiler where the safety-valve was, I found all right there; that is, there was no extra weight on the valve. I then slided the weight into the length of the lever, up to the fulcrum, where the weight was merely nominal, still the valve did not rise; I became confounded, and taking hold of the lever lifted on it pretty stoutly, and continued lifting for some seconds, when all of a sudden, with an explosion like that of a small field-piece, the valve opened, and the steam rushed out violently for some

* Franklin Jour. vol. ii. p. 142. † Franklin Jour. new series, vol. iii. p. 72. ‡ Franklin Jour. new series, vol. vi. p. 53.

time before it got down to the usual pressure, the engine being at work all the time. There was no water on the valve, nor any visible obstruction to its rising of its own accord after the steam got beyond the pressure of sixteen inches, which it had invariably done before; the valve and the valve-seat were both of the same metal. For many reasons I had not placed full reliance in the mercurial steam-guage, but had always entire confidence in the correctness and safety of the safety-valves; but in this case I was deceived, and perhaps in a few moments more an explosion might have taken place, for I had no doubt, if a small rod in the steam-guage could have had a free passage through the boiler deck, it would have denoted thirty instead of sixteen inches.

" It is usual to have the steam-guage so graduated, as to show as many inches of steam as the engine will take, and to have the safety valve loaded so as to agree with the steam-guage, believing that when the steam-guage indicated sixteen inches of steam, all the surplus steam would escape through the safety valve. Many engineers do not blow off any steam when the boat stops to make a landing, but depend wholly on the safety valve rising of itself, after the steam has risen a little above its required height. This has been considered a safe way of proceeding; but the case above stated, shows that it is wrong to depend too much on the safety valve." Mr. C. recommends that when a boat stops to land passengers, the safety-valve be raised, let the guage indicate what pressure it may. Before tne occurrence described, he believed the cause of boilers exploding was almost invariably the want of a sufficient quantity of water. He now thinks, that some explosions may be attributed to the being deceived by the safety-valve not rising as was expected by the engineer.*

The two following cases illustrate the necessity of attending to the proper form and construction of the safety-valve.

About six years since, a new copper boiler of one of the ferry boats plying between New York and Pawlus Hook, New Jersey, burst in consequence of the safety valve having been fitted too neatly, so that when heated by the steam it expanded and stuck. The boat had made several trips during the morning, and no steam had been observed to pass off for several hours.‡ The boiler was turned upside down, and flattened.

In another boat, on the Delaware, the escape pipe for the safety valve was of a conical form, the greatest diameter of which was below, so that when the valve raised, it closed the pipe, and prevented the steam from passing off. The defect was, however, observed, and an explosion prevented.

Explosions from overloading the safety valve have frequently occurred. The evidence of Mr. Richter before the committee of the House of Commons, p. 122, proves that the dreadful explosion of the sugar refinery in Wellclose Square, London, several years since, was owing to this cause. The engineer, being informed that the engine did not work well, put an immense weight upon the lever of the valve, so as to render it useless, still urging the fire, and in a few minutes it exploded, and blew the whole house to pieces. The same cause, according to Mr. Leet, produced the explosion in the tobacco manufactory at Chester, England, in July, 1822.†

Arago‖ mentions that from this cause the boiler of the steam-boat Rhone exploded on the 4th March 1827, and killed several persons. "Vexed at not being able to overcome the rapidity of the current as completely as he had hoped, the engineer fastened down the safety valves of all the four boilers; three of them burst almost simultaneously.

Another case occurred in a boiler attached to a wagon in Sunderland, England, by which several were killed.§

The Norwich (English) steam-boat exploded in part from the same cause. The attendant engineer seated himself on the safety-valve, in order to give his comrades the spectacle of the oscillating motion that he would undergo, as he said, as soon as the vapour should become strong enough to lift him. The valve did not open, but the boiler burst, and killed and wounded a great number of persons.

Arago quotes another case, of a steam-boat on the Ohio (name not mentioned), in which the explosion took place while the crew were engaged in weighing the anchor; when there was no consumption of steam, although the fire had attained its full force, and the safety valve was loaded with additional weight.

In 1803 the safety valve of a high pressure boiler in England, was fastened down by a boy, with a piece of timber, and rendered entirely useless for some time; and then the engine was stopped by another workman, who knew nothing of what the boy had done. Shortly after the boiler burst.‖

Several accidents have happened in the United States and other places, in boats from these causes. The rash conduct of the engineers or firemen was excited from an anxiety to beat other boats bound to the same places. All the particular cases in the United States cannot be mentioned, but they were stated at the time in the newspapers.

3. *Original Weakness of the Boiler.*

In the account given of the explosion of the United States steam-boat, September 1830, on the East River, New York, it was stated that in nearly all the accidents that have occurred in the New York waters, the ruptures have taken place in the same part of the boiler. In the Constitution, Legislator, Bellona, Chief Justice Marshall, and the Carolina, all low pressure boats, the rents were made in the lower part of the flues. In these boats there were no braces between the flue and the outer shell in the bottom of the boilers. The Constitution after her accident had them put in, and no explosion has since taken place. The United States boat, when the explosion happened, was going at her usual speed, with 12½ inches of steam, as had been ascertained two minutes before by the captain, who examined the guage. The boat could carry 13 inches of steam, and the boiler was so fixed that the steam blew off at 14 inches. The engineer had also just before examined the water cocks, and found that there

* Franklin Journal, vol. v. p. 355. † Philos. Mag. 1822, p. 67. ‡ Franklin Journal, new series, vols. v. vi.
§ Evidence before the House of Commons, p. 46. ‖ Philos. Mag. xvi p. 372.

was a sufficient supply of water. The part that gave way, viz. the lower part of the main flue, ten feet back of the bridge wall, had been repaired about a week before the accident, and four sheets of iron put into the flue. These were torn away, but the rivets remained in the old sheets. The boiler was of sheet iron of a cylindrical form, 22 feet long, and 8 feet in diameter, with what are called "kidney flues," forming one large cylinder, and one return flue; *and had been nine years in use.**

4. *Use of Internal Flues.*

In the United States steam boats, the fire is made under the boiler, which returns through flues passing through the boiler, and are connected with the chimney proceeding from it.† These flues, although always intended to be covered with water, often get uncovered from the causes before mentioned, and become red hot; the metal is expanded, and consequently has its cohesive power greatly diminished; and this being repeated may give rise to explosions at a time of apparently perfect safety. With careful firemen or captains there may be no danger of the water falling below these flues; but we know that the most wanton inattention has prevailed on board of steam-boats to this important point. It is therefore necessary to diminish the sources of danger to travellers, by placing them as much as possible out of the power of ignorant, obstinate, or negligent men. The four cases of collapses in Cornwall, referred to by Mr. Taylor,‡ occurred in boilers with return flues. The Chief Justice Marshall and United States, in the waters of New York, also had them; and several others that have exploded.§ They are indeed commonly introduced at present.

The Constitution (first named the Oliver Evans,) which was the first boat that exploded on the Ohio, was built with flues passing through each boiler, by Mr. Geo. Evans, who deviated from the plan adopted by his father. Having proved them with a pressure of 200 pounds to the square inch, and regulated the safety valve to 150 pounds, he thought them perfectly safe, but more might have been employed; if not, no other cause can be assigned than neglect to keep the water above the flues. He concludes by saying, "flues of this description are not safe, and ought not to be used."

On the western waters of the United States, flues are not only generally introduced into high pressure boilers, but under circumstances peculiarly dangerous. In a boiler of thirty inches diameter, the flues are from ten to sixteen inches in diameter, which often leave no more than a space of four inches between the bottom of the boiler and the lower flue, and from ten to sixteen inches for water and steam room; and hence from inattention on the part of the fireman, the water may soon fall below the flues, and by becoming red hot they are rendered liable to explosion. The flue of a boiler at Kensington, Philadelphia county, which collapsed, was sixteen inches diameter, and the two sides came close in contact. In the boiler at the distillery called Lochrin, near Edinburgh, and at the tobacco manufactory at Chester in England, the bottoms of the boilers, which were convex to the interior on the side next the fire, to allow the flame from the furnace to play in the centre almost of the liquid, were rendered convex outwards, so strong had been the pressure from within.

Mr. Taylor states that at East Crennis Mine, Cornwall, the inner tube was compressed as if the fire had softened the part above it, though there did not appear to be any other reason to think that the water was too low. At the Mold mines in Flintshire, the inner tube was not moved from its place, although it was very much flattened for a great part of its length, the sides having come together.

A writer under the signature "An Engineer," in commenting upon the cases of explosions in Cornwall, related by Mr. John Taylor, says he "considers the introduction of a tube within a high-pressure boiler to be bad under any circumstances, but it is particularly so where the furnace is placed in it. The ash-pit, also, is by necessity most objectionably small, where the furnace is inside the boiler. This is an evil of some magnitude, both as regards the draught, as well as the wear and tear of fire-bars."‖

5. *Material Composing Boilers.*

Boilers were frequently made of cast iron when steam-boats first began to run, and gave rise to many explosions, owing to internal defects of the iron, and to its liability to crack from heat. Wrought iron is therefore now generally substituted. It is also preferred to copper, from its greater tenacity. But when salt water is used, copper is preferable, because it acts less powerfully upon the deposits from it than iron. Cast iron even for the ends of boilers is objected to by O. Evans, unless the fire be kept from them, owing to their liability to crack when heated.

6. *Use of metals of different expansive powers for boilers.*

To this cause may in part be attributed the explosion of the Norwich Steam-packet. It was ascertained that the boiler, although cylindrical, had one end of cast iron, the other of wrought iron. These ends were flat. The cast iron end was only $\frac{3}{4}$ of an inch thick, and it was this end that gave way. The body of the boiler was composed of wrought iron. The propriety of only using one kind of metal for a boiler must be obvious.

7. *Weakness of the boilers from long use; unequal thickness in the metal; and raising steam too high for its strength.*

The influence of these causes is apparent to all. A boiler sent to Mr. Oliver Evans to repair, had been reduced to the thinness of paper in se-

* Poulson's American Daily Advertiser, Sept. 4, 1830, from the New York Courier.

† The high pressure boilers of Rush and Muhlenberg have no internal flues.

‡ Philos. Mag. 1827, p. 126.

§ On the authority of an experienced steam-boat navigator, it can be stated that the rent in the Chief Justice Marshall took place at the farther extremity of the main fire flue, and the water was driven through the doors toward the forward cabin, and killed and scalded all who were in the fire room The Constitution boiler had D flues; and the collapse took place on their flat sides.

‖ Philos Mag. 1827, 405

veral places, and had been used in this dangerous state for some time. It had discharged its steam in two or three instances, through a small vent, without however injuring any one. A boiler of the low pressure steam-boat Bristol collapsed, from this cause, in the spring of 1820, in the Delaware. There were two boilers, one on each side of the engine, connected with steam and water pipes. The top of the furnace was flat. The boilers were old and corroded, and the captain, who is still living, says that "they ought to have been condemned before he took charge of the boat. There was a great competition from four boats at the time, and the Bristol being ahead of a better sailing boat, belonging to another line, the engineer desired the fireman to increase her fire to preserve her distance. The fireman replied that there was as much fire as was necessary, and if he wanted more he might make it himself. He did so, and suffered for his folly. While the captain was in the fire-room, he was alarmed by the leaking of the boiler, followed speedily by a tremendous hissing of steam, and retreated in time. On inspection, it was found that the furnace or flue, in the centre of the boiler, had been forced inward, and the steam and water from both boilers had rushed into the fire of the injured flue, or inside shell of the boiler."

The boiler that exploded at the Union Rolling Mill, Pittsburgh, was worn out.

The boiler of the sugar refinery, in Well-close Square, London, was of different thicknesses. At the bottom it was two and a half inches in thickness; on the two vertical faces, an inch and a half; in the lower part of the dome, not more than seven-sixteenths of an inch; and in one place, the thickness was reduced to an eighth of an inch. It was of cast iron.*

The explosion of the Norwich was in part owing to one of the causes noted. Mr. Tilloch observes that "it was usual to raise the steam to a pressure of 70 lbs. to the inch before starting for the voyage; the end of the boiler was quite incompetent to hazard such a pressure, and the steam was urged beyond all prudence to beat a rival boat. The wonder is, that it did not explode long before, for it was more common to have steam at from 100 to 120 than even at 70 lbs. to the inch."†

The boiler of the boat Tricolor (low pressure) exploded at Wheeling on the 19th of April 1831, by which eight persons lost their lives, from the immediate effects of the explosion or by drowning; eight others were scalded very severely. A private account states, that the boiler was 13 years old, the Tricolor being the third boat on board of which it had been placed; and for several hours before the explosion a hot fire had been kept up.

8. *Form of the Boiler.*

Mr. Evans, from his first attempt to make steam-engines, was aware of the superior strength of the circular form for boilers. In his "Steam Engineer's Guide," he says, "a circular form is the strongest possible, and the less the diameter of the circle, the greater the elastic power it will contain. Therefore we make cylindrical boilers not exceeding three feet, and to increase their capacity, their length is extended to 20 or 30 feet, or their number increased."

The adoption of the cylindrical form for boilers, evinces the correct philosophical principles upon which Mr. Evans acted. Nothing can be more clear than that by this form the expansive force is equally exerted over the whole of the internal surface of the boiler, and consequently that the steam will have no effect tending to change the form. Experience has proved the justness of his theory.

To ascertain the power exerted by steam to burst one of those boilers, and the thickness of iron necessary to hold it, Mr. Evans gives a rule, example, and demonstration of the problem of a circle 36 inches diameter, the result of which is, that 54,000 lbs. weight are required to break the two sides; half of which, 27,000, are necessary to break one side in any one place. To the solution of this useful problem, which he never met with, he adds a table, showing the power exerted to burst each ring of one inch wide of the boilers of different diameters, and the thickness of iron necessary to hold steam of power equal to 1500 lbs. to the inch area.

In another publication he illustrates the strength of this form by a familiar illustration. "It will bear," he says, "greater elastic power than boilers of other forms, in the proportion that a bar of iron will bear more pulling straight end-wise, than it will on its middle, to bend and break it when laid horizontally, supported at the ends." Boilers, however, are not always made in this form, and, to compensate for the deficient strength of other shapes, stay bolts are used.

The boiler of the London sugar refinery, already referred to, was made of flat iron pan, of eight feet diameter: therefore, extending the bursting surface in proportion of four to sixteen.‡

Connected with the form of the boilers, is the mode of their construction, and applying the fire. In Cornwall the most common arrangement is to fix one tube within another; the interior one containing the fire-place, and the space between it and the exterior containing water, and in the upper part, steam. The ends of the boiler fix the tubes together, so that the interior tube is opened at both ends, at one of which is placed the fire grate, and at the other the smoke and flame pass out, and are conveyed to the stack or chimney most commonly by flues passing under and along the sides of the outer case. They are from 20 to 35 feet long, and from 3 to 4 feet in diameter; the outer one from 5½ to 6½ or 7 feet. Four accidents by collapsing, according to Mr. J. Taylor, occurred in the two or three years preceding 1827, from the use of boilers of this description: the particulars of which he gives.§ The fire is now made under the boiler. Arago mentions several more that occurred in France, in similar boilers. Boilers of this description were formerly very common in the United States, but are now entirely given up.

9. *Sediment in Boilers.*

This cause has frequently produced bursting of boilers, and the inattention to it by those who own steam-engines, or command steam-boats, is truly surprising. It is evident that a crust formed within or upon a boiler, offers a non-conducting material to the heat from fire or water; and that the bottom of a boiler, the inside of which is so coated, will require much more fuel to bring the water to the boiling point, and to keep up its temperature, than if this obstruction did not exist. Hence arises additional expence. This increased operation of the fire on the metal softens it, and allows the expansive force of the steam to push it out like a bull's-eye glass light, to the extent of several inches in diameter, thus diminishing its substance. Mr. Burr states that the protusion of the bottom of a boiler at Richmond, Virginia,* was as large and as deep as a hat crown, from sediment collected in four or five weeks. The protusion in the bottom of a boiler of an engine in a cotton mill at Kensington, Philadelphia county, from the sediment three inches thick collected on it, was about half that size. The sediment when picked off, will bring scales of the iron with it, and thus tend to lessen the thickness of the bottom plate still more. When the water is over the fire flue, the sediment will descend to the legs, and space in front of the boiler. The effect of a continued application of fire to the metal of boilers thus expanded and weakened, may easily be conceived. The fire and accumulated coals finally burn out the part, the water and steam then rush below, and the pressure from above will cause a collapse of the boiler. This was probably the case of the Legislator of New York. Several years since one of the four boilers of the high pressure engine at Fairmount Waterworks, on the Schuylkill, was burnt out from the collection of sediment in one end of it. The deposition of the sediment in that part was promoted by the position of the boiler, which, in order to favour the operation of the fire, was fixed so that the farther end was several inches lower than the door end. The boiler had been cleansed the day before the accident, but, owing to the difficulty of reaching the further end, it was neglected, and a thick hard crust, to which the grease in the water greatly contributed, was permitted to remain. The rent took place under this crust; the water ran into the ash-pit, and followed by that and the steam in the other three boilers, rushed out with a mass of ashes, closing the door of the ash-pit, which opened inwards, and filled it in an instant. Two men were severely scalded, and additionally suffered from the inhalation of ashes and hot steam, in which they were enveloped: they died within two days.

When the Etna ran in the Delaware, with a high pressure engine, a leak in the bottom of the boiler took place, owing to the collection of sediment in it, but no injury was sustained by any one: and the bursting of one of the boilers of the Bristol, already mentioned, proceeded from the same cause, according to the opinion of the captain. "The small space between the bottom of the furnace and the outside shell, was very difficult to be kept clean, and that was the spot where the rent took place." This was doubtless heated red from the accumulation of coals underneath the bars of the grate. The boats plying in the muddy and sandy waters of the western country, are particularly subject to danger from the accumulation of sediment.

10. *The Sudden Increase of the Pressure of Steam on a Boiler.*

A sudden increase of pressure of the steam on a boiler, there can be no doubt, has often occasioned explosions which could not be accounted for by any apparent defect in it, owing to the unequal expansion of the metal which ensues, on the same principle that hot water poured into a glass or china cup will cause it to crack. The bursting of the boiler in the tobacco manufactory at Chester in England, already referred to, took place from this cause. Mr. Leet relates that "it was connected with machinery requiring steam of great expansive force for its movements, and when used for the first time since its repair, the steam was speedily raised in such a powerful manner, that the boiler was perceived to have an oscillating motion for a considerable time, and finally exploded, spreading desolation all around." A greater pressure, if produced gradually, might not have been attended with any rupture.

It has been mentioned that owing to the explosion of the Etna, a prejudice arose against high-pressure engines for steam-boats, and that those in the Atlantic waters have since that time been supplied with others on the low-pressure principle. The term low-pressure is, however, most commonly, merely nominal; for there are few boats professedly working with low steam, that do not carry many more pounds to the inch than the low-pressure principle, or the strength of their boilers will warrant. On the western waters this is notoriously the case. From a well-informed and highly respectable source, it can be stated, that "many boats in those rivers run under the name 'low-pressure,' merely from the circumstance of their having the condensing apparatus, and from disposing of the steam by that means as distinguished from those which suffer it to escape in the air, although it sometimes happens that the condensing boat uses steam of a greater density than the other, called 'high steam.' Boats thus working the high steam, but condensing, are technically termed '*medium* engines.' It was formerly thought that a good vacuum could not be maintained in the condenser when working high steam, but practice as well as theory teach otherwise, for from the same boilers and fuel burnt, an equal quantity of heat passes to, and has to be overcome by the condensing apparatus, whether the steam operate through a small cylinder under high pressure, or through a large cylinder at a consequent low-pressure. It is not unfrequent for boats on the Ohio and Mississippi, which condense their steam, to work it as high as eighty to one hundred pounds per square inch; now the nett gain by condensing is not in any engine much over ten pounds to the inch, so that this little apparent increase of force is scarcely worth the expense and care of condensing;" and besides, it is lost by the reduction of temperature, which must be below one hundred and seventy degrees; whereas when supplied from a high pressure engine, the water would be two hundred and twelve degrees; but the steam is disposed of in an insensible manner, and the boat obtains the security-creating name of "Low Pressure:" how justly, let the above remarks determine.

* Franklin Journal, new series, vol. vi. p. 334.

It has already been stated, that notwithstanding the prejudices in the public mind against high pressure engines on board of boats, those propelled by low pressure, were as much liable to explosion as others driven by high steam. The following list comprises the cases of some of the accidents, which have occurred in low pressure boats.

1. Paragon of New York, built by Mr. Fulton.
2. Atalanta, running between New York and Elizabeth Town.
3. Washington, on the Ohio, June 1816.
4. Powhatan, between Norfolk and Richmond, March 1817.
5. Bellona, New York and New Brunswick, March 1822.
6. Eagle,* Baltimore and Annapolis, April 18, 1824.
7. Maid of Orleans.
8. Cotton Plant of Mobile.
9. Superior, of Charleston, South Carolina.
10. The Rariton, of New York.
11. Oliver Elsworth, March 1827, near Saybrook, Connecticut.
12. Constitution, 1825, North River.
13. Legislator, } Waters of New York.
14. Carolina, }
15. Franklin, }
16. Chief Justice Marshall, off Newburgh, North River, New York, April 22, 1830.
17. United States, Sept. 11, 1830, in the East River, New York.
18. Tricolor, at Wheeling, on the Ohio, April 19, 1831.

In all of the above cases, more or less persons were killed outright, or died soon after being scalded, or were disfigured or crippled for life. The greatest number suffered on board the Helen M'Gregor. Fifteen hundred persons, it has been computed, have *lost their lives by explosions of steam engines in American boats.*

Collapsion of boilers.

"Boilers constructed of plates of laminated copper, or iron, *low pressure boilers particularly*, are subject to accidents from collapsion." Some cases of this kind in American boats have been mentioned in the preceding pages; it not having been thought necessary to separate them from those strictly called "explosions," and which proceed from the expansive force of steam. "These boilers," says Arago [or their internal tubes], "are sometimes completely crushed; the sides bending to the pressure from without. The cities of Lyons and Etienne in France have been the theatres of several accidents of this kind. The inner cylinders of boilers having the furnace and flues within, give way occasionally, from their inability to resist the pressure of the steam in the circular space around them, and become flattened; this change of figure cannot take place without the metal giving way, and hot water thus escaping produces dreadful havoc. Four collapses took place in Cornwall, of boilers of this form, as has been already mentioned, p. 447. "An engineer" in commenting upon these accidents† says, "that as far as appearances after explosion are to be relied upon, they were such as to justify a suspicion, that the boilers were short of water;" and condemns their construction.

Arago mentions another cause of collapse. "At the time of lighting the fire under a boiler, the space within the boiler not occupied with water is filled with atmospheric air. This air mixed with steam passes by degrees into the engine fed by the boiler, and at last is completely expelled therefrom. If the machine be stopped, and the fire suffered to go down, the steam will be gradually condensed as the cooling proceeds, and after some time, the space which it occupied will be almost void. The boiler is then pressed inwards by the pressure of the atmosphere, without there being any interior force to counterbalance the action. A sudden condensation would crush the boiler. To prevent such accidents, interior valves called air valves opening inwards were invented. They are kept in place by a spiral spring within the boiler, the strength of the spring being a little more than equal to the weight of the valve; or it is suspended horizontally to the arm of a lever, placed on the outside of the boiler, so arranged that the valve exactly touches the interior face of the opening, which it is to close. With this arrangement, the elasticity of the steam within the boiler, can never become less than that of the atmosphere, without the immediate opening of the valve, which will admit the air into the boiler; thus when the engine is stopped, no vacuum will be formed within the boiler.‡ It seems that we cannot so safely conclude, that the same arrangement would prevent certainly the crushing of the boiler, for such accidents result from an abrupt diminution of elasticity in the steam. The gradual action of the valve might, to a certain degree, lessen the evil, but could not prevent it. *There is but one remedy against such accidents:* to watch carefully the means of supplying the boiler, and to prevent the reservoir of steam within the boiler from being suddenly cooled, as would happen for example, if a quantity of cold water should be thrown upon the exterior. It is important also when we use this kind of boiler, not to close the register doors until the fire is extinguished."§

* The Eagle formerly ran from Philadelphia to Bordentown, New Jersey, and at a time when there was not a high-pressure boat on the Delaware. We may judge whether a low-pressure engine can do mischief from the account of the captain of the Constitution, who assisted the people of the Eagle soon after the explosion. He says, "the after head of the starboard boiler bursted into atoms;" and, "I never saw so complete a wreck below decks." He tells us further, that one part of the boiler went aft to the ladies' cabin, and another killed a soldier who was asleep in the forward cabin. It is somewhat remarkable, that this tremendous explosion scarcely excited a remark in our newspapers; there was no clamour raised against low-pressure engines in consequence of the accident.

† Philos. Mag. 1827, p. 403.

‡ A puppet valve reversed answers the purpose; they have been long in use in stills to prevent a collapse.

§ An explosion was produced in a common close stove in Philadelphia, from covering a fire of anthracite coal with wet ashes, at night: on re-lighting the fire with shavings and charcoal the next morning, an explosion took place in a drum connected with the stove, and placed in the second story of the house, of which the stove occupied the ground floor: part of the drum was thrown with violence against the ceiling of the room. "By the heat remaining in the stove, a carburetted hydrogen gas was evolved from the shavings, and formed with the atmospheric air in the drum and stove pipe, an explosive mixture. An analogous result, upon a more limited scale, may be frequently observed, when paper or shavings are thrown upon a fire where there is no flame so situated, as immediately to ignite the gas evolved. If a piece of paper had been lighted beforehand, and thrown on the top of the mass, the explosion would have been prevented.—*Dr. Hare, Franklin Journal*, new series, vol. vi. pp. 414, 337.

A NEW SOURCE OF DANGER.

On the 30th Sept. 1830, a joint in the pipe that conveyed steam from the boiler of the steam-boat William Peacock, of Buffalo, New York, gave way, and instantly discharged the whole head of steam into the steerage cabin on deck, killing and scalding several persons. Here is another point to which a careful captain ought to direct his attention. It is truly shocking to think of the sacrifice of lives, from the sheer neglect of the captain of a boat to guard against every possible source of danger; and criminal on the part of those guilty of it.

MEANS OF PREVENTING EXPLOSIONS.

Several of the causes which have been ascertained to produce explosions, having been mentioned in the preceding pages, it follows, that the means of preventing these fatal occurrences, are to guard against their causes. It is a fact, that the greater part of these explosions have originated from the wanton folly, neglect, or inattention on the part of those, to whom the management of the fire is committed.

1. *Metal for Boilers.* The first point to be attended to is the material of which the boiler is made. The propriety of rejecting cast iron, and substituting wrought iron, has already been mentioned. Where salt water is employed, copper is preferable, as it does not decompose water at any temperature, and hence an incrustation of oxide will be less liable to be formed internally, in a boiler of copper, than in one of iron; for this metal, at a high temperature, rapidly decomposes water *per se*, and with the aid of various salts or acids, decomposes it at the ordinary temperature of the air, and still more rapidly, at, or above boiling heat.

2. *The form of the Boiler.* No other than that of a cylinder should be permitted, for reasons before given.

3. *Strength of the Boiler.* The third point would seem to be, the strength of the boiler.

It has long since been proposed, that every boiler intended to be used under steam of high pressure should be previously proved by injecting, by means of forcing pump, cold water into it, while the safety-valve is loaded with a much greater weight than is to be employed when working with steam; or Bramah's hydraulic press may be employed.

The water-proof having been performed, the boiler should be next subjected to a similar trial by steam, of twice the force that is usually to be generated in the boiler, without causing the safety-valves to act. In France it is required by law, that all high pressure boilers be subjected to a proof five times as great as the boiler is intended to bear, when in service. Arago says that this pressure is reduced to three times for boilers of rolled or hammered iron, but that even these do not afford entire security. He judiciously remarks that "these trials only show what a boiler can bear when new, not what it will be able to sustain after some weeks, or some months use; after inequalities of temperature have strained the metal in every direction; or after rust has acted upon it," &c. A boiler should therefore be proved from time to time, and occasionally examined to detect any weak part.

Mr. Bramah in confirmation of this advice may be quoted. He says, if a boiler was prepared to sustain one hundred pounds, and strained with a force of two hundred pounds, it might afterwards break at forty, the straining having injured it.* The extreme proof required in France is injudicious. A proof of double the pressure intended to be used would seem sufficient; more might defeat the object of the trial. Mr. Vivian adds, that explosions may be easily prevented by proving the boiler every time it is cleansed, which should be at least every month.† John Taylor says in proof of this, that a cast iron boiler was proved to one hundred pounds to a square inch, by the water proof, and commonly used with about forty pounds pressure, but it broke one day with less than twenty pounds pressure; the fracture being caused by the heat expanding unequally.‡ Mr. Donkin has known a boiler wear out in six months; and another used for fourteen years.§ Mr. Dodd says, that when a wrought iron boiler will not support the cold water test of twelve pounds to an inch, it is time to have a new boiler.‖

4. *Size of the Boiler.* Mr. Evans never exceeded the diameter of three feet, and to increase capacity extended their length to twenty or thirty feet, or more; or increased the number. Messrs. Rush and Muhlenberg, his successors, now make their high pressure boilers of thirty inches diameter. The "Engineer," before quoted, restricts their diameters to five feet; from which it would seem that in England high pressure boilers are sometimes of a greater diameter.

5. *Height of the Water in the Boiler.* As it has been ascertained, that the greater part of the mortality from steam explosions proceeded from inattention to the great point of keeping up the due supply of water in the boilers, this should never be lost sight of. Captains of boats ought not to trust this business solely to the engineer or fireman.

To ascertain the height of the water in the boiler, it is well known that the original expedient, and the one commonly used, consists of two stop-cocks in front of the boiler, one of which communicates with the water, the other enters the boiler above it. The issue of steam from the first indicates the deficiency of water, and the discharge of water from the last, shows that it stands too high. But these cocks do not upon all occasions answer the end intended by them. Mr. Potts observes,¶ "when an engine runs regularly, it is not difficult by this means to make the supply of water to the boiler by the hot water pump equal to the evaporation; but every variation that takes place with regard to the load with which the engine labours, or the velocity with which it runs, tends to disturb the equilibrium between the supply of water and the evaporation, attained by any previous adjustment of the pump. Again, when a temporary stoppage of an engine is necessary, as for taking in, or discharging passengers, the fire is rarely abated to such a degree

* Evidence before the Committee of the House of Commons, p. 38. † P. 163. ‡ P. 43. § P. 8. ‖ P. 213.
¶ Franklin Journal, 1830, p. 42, vol. vi. new series.

as to prevent all further evaporation. The supply from the pump being cut off, the water sinks rapidly."

Cases have even occurred in which explosions have happened in the boats of the United States, when going at their regular speed, as was shown by the steam guage, if the solemn asseverations of the captains are to be believed, and immediately after the water-cocks had been opened and indicated the supply. The boats Etna, United States, and Chief Justice Marshall, are cases in point, as has already been mentioned under the third head of the causes of explosions.

This fact shows clearly, that implicit reliance ought not to be placed for safety, upon the guage-cock emitting water. But further, " even where the water is not so far reduced in the boiler, as to be below the top of the tube, I am by no means inclined to consider this boiler in a safe state. The plates of a boiler urged by an intense fire, and covered with only a thin stratum of water, become very considerably hotter than the steam and water above them. The unequal expansion resulting therefrom, renders the parts more disposed to give way, when further stress comes upon them."* A boiler or flue therefore, repeatedly thus treated, may give way upon the occasion of an extra strain from high steam, although the guage-cocks will show water in the boiler. This deficiency in the guage-cock may be remedied in low pressure stationary engines, by the means mentioned by Mr. Farey as having been used by Mr. Smeaton, viz. " A pipe going down beneath the surface of the water in the boiler, and at the upper end of the pipe, at the top of the house, a whistle mouth-piece is formed; then, if the water sinks too low, the steam will issue at the pipe, and give the alarm."†

Professor Hare proposed that a hollow globe, swimming on the water of the boiler, should open a small cock so as to produce a jet of steam in front of the boiler, whenever the water should sink too low.‡ This contrivance is applicable to high and low pressure engines; an objection to it has been raised, viz. that by frequent expansion and contraction, the parts soldered together have opened so as to cause the vessel to fill with water and sink. A little attention may certainly obviate this difficulty. Pumice stone is used as a float, for Watt's feeder at the Globe Mill. The glass tube water-guage will afford additional means to determine the height of the water.

With the same object Mr. J. L. Sullivan has invented an *alarm bell-float*, and *phonic guage* for boilers; the object of which is to cause the water itself to give the alarm. For this purpose he uses bells or metallic triangles within the boiler, to ascertain where the surface of the water is within certain limits. The principle of their operation is founded in the fact, that bells emit a louder sound in compressed air, than in the atmosphere. Two bells are to be placed in a boiler, one an inch higher than the other, with suitable wires leading from each tongue through packing to the front of the boiler: if the lower one touch the water it will not ring, while the upper one being above the water will sound and be heard; thus making it known that the surface is between them. It is intended to ring spontaneously, whenever the water shall happen to subside so much as to make bare and expose the furnace or flue to the action of the fire within; or if a single cylindrical boiler exposing some part of the sides to the action of the fire without, or under, whereby the flue or sides unprotected by the water might become red hot, and impart great heat suddenly to the water, and causing so great an increase of high steam, that the safety-valves cannot vent it. A specification of this plan is contained in Silliman's Journal for 1831, and deserves an experiment by all those to whom passengers entrust their lives, on board steam-boats.

To insure a constant and due quantity, Mr. Watt contrived a simple plan for low pressure stationary engines, by which the engine is made to supply the boiler. One of these is in use at the Globe-mill Cotton-works, near Philadelphia. Mr. Doolittle of Vermont has invented another, and described it in the Journal of the Franklin Institute, vol. iv. This feeder, like that of Mr. Watts', has a regulating cock, or valve, between the forcing pump and boiler, and the pump must continually urge towards the boiler its maximum quantity of water, whether the boiler is in a state to receive it or not. Mr. Charles Potts of Philadelphia, has recently taken out a patent for an invention to effect the same object; an account of it may be found in the Franklin Journal for 1830, vol. vi. pp. 42 and 327, illustrated by a plate. His object is to secure the self-action of the supply pump, by the falling and rising of a float in the boiler. In the same work and volume Mr. Ewbank of the state of New York has proposed another plan, and with the exception of this principle, somewhat on that of Mr. Potts; who announces that Messrs. Rush and Muhlenberg, of Philadelphia, will attach his apparatus to engines. In vol. vii. p. 183, is a specification of another patent granted to John S. Williams, of Kentucky, for the same object, with a cut illustrative of the apparatus. Finally, Mr. Farey§ describes at length, and figures a contrivance wherewith the boiler will always feed itself as fast as its evaporation requires; the water being admitted by a feeding valve, which is opened by a float on the surface of the water in the boiler. *This is the mode adopted in England.* With all these contrivances to prevent a common cause of explosion, no admissible excuse can be offered by proprietors of boats, for deaths which may take place for want of them.

6. *To lessen Sediment in Boilers.* In the collieries in Scotland, where steam engines are applied to the drawing off the water in mines, the earthy sediment has been found very troublesome, but its deposition is prevented by the simple expedient of throwing a bushel of *comings* into the boiler once a week. This substance is the radicles of barley produced in the process of malting, which are separated before the malt is sent to market. Mr. Bald of Alloa says,‖ the effect is immediate when the steam is again raised. When sulphate of lime (gypsum) is held in solution by the water.

* An engineer. Philos. Mag. 1827, p. 406. † Farey on Steam Engines, pp. 193, 370. ‡ Franklin Journal, vol. ii. p. 148.
§ On Steam Engines, p. 453. Lond. 1827. 4to. ‖ Edinb. Philos. Mag. 1820, p. 340.

they use *peat earth* in its natural plastic state. From Silliman's Journal vol. vii., it appears from a statement of Professor Griscom, of New York, that potatoes have long been used in the United States for the same purpose. Arago says that they answer even when the deposit is saline, by which it is presumed, he alludes to the contents of salt water. The diffusion of the starchy feculæ through the water forms a viscid liquid, which envelopes the solid matters of the water, and keeps them suspended, and prevents their cohesion. After a month's service, the boiler is emptied.

To prevent the formation of sediment in the boiler, one of the experienced captains on the Delaware says, that the water should be changed while the boat is under way, as the sediment would thus be made to flow out of the legs of the boiler and space in front; and to determine whether the force pump supplies as much as is let off, and the flues are covered, one guage cock should be kept open. The superb boat, Robert Morris of Philadelphia, the works of which were made by Mr. Holloway, has not only a man-hole to clean the boiler, but additional facilities to remove sediment, consisting of a vent hole or tap in each of the three front legs of the boiler, a hand hole covered with a screw plate, in the middle front leg; two hand holes, one on each side of the further end of the boiler, and another hand hole on the side of the boiler, opposite the bridge wall.

The apparatus adopted at the mint, and formerly referred to, to lessen the deposit in a stationary engine, is as follows.

The operations of the coinage in the Mint at Philadelphia are effected with the aid of one of Oliver Evans' high pressure engines. For sometime after its erection, the grease from the cylinder, being carried into the boiler with the water of the condensed steam, united with the earth in the water of the boiler, and forming a hard sediment on the bottom plate caused it to burn out. The boiler being mended required to be cleansed once a month. To lessen this trouble, and prevent the frequent suspension of the work, Mr. Eckfeldt, chief coiner, some years since adopted the following plan. He surrounded the escape pipe with a copper cylinder twelve inches in diameter, and containing thirty gallons of water, which is let into it by means of a pipe lying on the side and near the top of the cylinder, and kept constantly hot by the steam in the pipe. The steam passes into a cast iron reservoir; the portion of it condensed flows into a sink through a hole in the side of the reservoir, with the filth from the cylinder, while the uncondensed portion of the steam is conveyed up a pipe fixed in the top of the reservoir, and leading into a chimney. When the boiler requires replenishing, the hot water in the cylinder is let into a reservoir, and forced into the boiler. Thus, while there is great economy in supplying the boiler with hot, instead of cold water, the deposition of the hard crust on the inside of the bottom plate is greatly lessened, and no sediment precipitates but that which is formed from the earth contained in the water, with which the copper cylinder is filled. This is so trilling, that the boiler does not require cleansing oftener than once in three or four months. From the great head on the Schuylkill water, the workmen are enabled to draw off the heated contents of the cylinder, by merely fixing a pipe to the aperture in its top, intended for the admission of the cold water. This heated water being in perpetual requisition for various purposes about the establishment, the constant supply of it is found a great convenience. A safety valve in the cylinder prevents all danger from the too great accumulation of steam in it.

7. *Safety Valves.* Under the tenth head of the causes of explosions, six particulars are enumerated, all tending to disappoint the expectations of security from safety valves; and in the commentary upon them, some facts in illustration are given. It seems astonishing that an error should be committed as to their diameter, and yet such is said by a careful and experienced steam-boat navigator to be often the fact. As the rules for their construction are well understood, and fully laid down, it is criminal for those who undertake to make an engine, not to avail themselves of the important knowledge in their power. This may be obtained by consulting Mr. Farey's large work, or that of Mr. Renwick, p. 86. The object of the present article is not to enter in the minute details of the mechanism of engines, but to point out the causes of the dreadful explosions that have taken place, and to suggest the general means of preventing them. The adhesion of the disk should be constantly guarded against; in the case of the Legislator already noticed, the vigilance of the engineer, and his prompt attention, probably prevented the occurrence of a most serious explosion from this cause. To prevent the possibility of an adhesion, Mr. Mausdlay, an experienced worker of steam in England, placed near his boilers a cord within reach of the fireman, by which he could raise the safety valve from time to time. But this is not enough. Supposing that the valves are properly constructed, it has often been recommended to have two to every boiler, one under the control of the fireman, to be used whenever the steam is to be let off; the other to be inclosed by a grated box, of which the engineer, or captain of the boat, proprietor, or superintendant of the engine, should have the key. Arago says, that in France a royal ordinance makes this precaution absolutely essential; and the government of the United States, or the State Governments, should follow the wise example. The preservation of 1500 lives, which may again be lost in the course of a few years, by inattention to the subject of steam-boats, is certainly of more importance than the inspection of hog's-lard and butter for exportation, for which strict laws are in force.

Mr. Dodd, an eminent British steam engineer, "disapproves of those safety-valves which have a conical seat, as they are liable to be jammed in, and also fastened by contraction: and also those that are pressed down by a weight on a lever, as accident or design, by altering the position of the weight, may increase or decrease the pressure, and they are peculiarly inapplicable to the motion of vessels at sea. With lever safety-valves even the most cautious man may, in the hurry of business, place the weight too far out on the lever, and if the lever be too short to admit this, rash men frequently put on an extra weight, and thus endanger the property and themselves, and those on board. The best inaccessible valve* is formed by fixing round the hole or orifice on the boiler, a circular brass ring flat on the upper surface. From the centre of this ring, and secured to the under side thereof, arises a spindle or pivot, passing into a cylinder closed at the top in the middle of the valve and weight. This pivot should be grooved on the sides, to allow the entrance of steam; and should not extend to the top of the cylinder, nor fit tight by the tenth of an inch. This cylinder has a *brass flat bottom resting* on the flat circular ring, and both surfaces so finely ground as to be air and steam tight: valves similar in this respect have been long and successfully used. A leaden circular weight, having a hole up the centre, is placed over the brass tube or cylinder, and rests on its base. The whole is surrounded by an iron box rivetted to the boiler, and has a lid fitting tight and locked. From the side of this box passes a pipe of sufficient bore to convey away the escape steam. The steam from the accessible or common valve is conveyed by a pipe through the vessel's side into the water, and to prevent a vacuum in this pipe, and the cold water rising up to the safety valve, connected to this steam-escape-pipe is a reverse or atmospheric valve. That it may be known when the accessible safety valve is out of order, we pass the escape-steam-pipe of the inaccessible valve into the paddle boxes, from whence the steam will be heard and seen to issue in the event of that valve being forced to act; and all on board may know that something is wrong with the other valve. Yet this circumstance should create no alarm, for however much he may urge the fire, the steam will escape by that valve, and foil his utmost effort to raise it to a dangerous strength."†

These particulars are given, as Mr. Dodd's work is not common in the United States.

8. *Steam Guage.* Ample and afflicting experience having demonstrated, that safety-valves do not on all occasions afford security against explosions, no steam-engine on shore, or in a boat, should be without a mercurial Steam Guage. For, "although the load on the safety-valve makes a sufficient regulation of the strength of the steam, to avoid any danger of bursting the boiler, it is not a sufficiently accurate indication, to enable the engine man to keep up the steam always to the same elasticity. Mr. Watt, therefore, employed a steam guage, which operates by a column of mercury. This steam guage consists of an inverted syphon, or bent tube of glass or iron; one leg of which communicates with the boiler, being joined to the steam-pipe, and the other is open to the atmosphere. A quantity of mercury is poured into the tube, to occupy the bent part which joins the two legs; and the mercury in merely being exposed to the pressure of the steam, while the external air acts upon the other, it is evident that the difference of level of the two furnaces, will express the elasticity of the steam above or below the atmospheric pressure, by the height of a column of mercury it will support. When the tube is of glass, this difference of level may be seen and measured on a scale of inches; but when an iron tube is used, a small light wooden rod, floating on the surface of the mercury in the open leg, points out the height of the column against a scale of half inches, fixed above the open end of the tube. In this case, the divisions, which are numbered for inches, must be only half inches; because the mercury will descend in one leg, as much as it rises in the other; so that the scale must be doubled, to show the real difference between the two surfaces.

"The tube is made of wrought iron, in the same manner as a gun-barrel, but with the two ends bent parallel, like the letter U: the interior of the tube ought to be bored, in order that both legs may be precisely of the same diameter, otherwise the guage will not show the pressure correctly, because the mercury will not sink so much in one leg as it rises in the other. A steam guage of this kind is usually attached by two screws to the steam pipe, or else to the end of the boiler, or at any part having open communication with the boiler, and in a convenient place for the engine keeper to see it, because this should be his constant guide for the regulation of the fire and the damper." ‡

If this steam guage be properly fixed, so as to be always kept upright, and of a diameter adapted to the size of the boiler, it can never fail to point out the elastic force of the steam within it; as by the rising of the mercury, which is shown on the scale attached to the tube, the fireman can ascertain at once, whether the pressure be greater than the boiler is calculated to bear. If the mercury becomes stationary, it would instantly point out that the tube was stopped, and give time to guard against danger. "It is also a capital counter security to the valves, for if this guage indicate a higher pressure of steam than that at which the valves ought to rise, the engineer may know that they are impeded, and rectify the error. It is the duty of the man frequently to look at this guage, that he may know when to increase the fire in the furnace, and occasionally to tap the guage, that by the excited action of the mercury, and the indicating rod (where the syphon is not of glass but of metal), he may be assured that the action of the guage is free and uninterrupted. Every steam packet on the Thames is provided with one of these guages."§ The utility of the steam guage was shown in the case of the Legislator of New York (p. 445). The rod rose as high as the deck would permit, thus proving an immense pressure on the boiler.

9. *Plates of Fusible Metal.* "As soon as it was found that the common safety-valves sometimes got out of order, and did not present a certainty of security, it was proposed to replace them by an entirely different contrivance, the action of which should never be uncertain. This was the fusible metal valve, described in the 'Annuaire du bureau des longitudes' for 1829 and 1830. To understand rightly the use of these valves, we should know, that it is possible for steam to have a very high temperature, with but little elasticity, but not possible, that a great degree of elasticity, should not be accompanied by a high temperature. Experimenters have determined the lowest temperature necessary for steam to acquire

* Inaccessible, except to the one who has the key of the box containing it.

† Dodd on Steam Engines, p. 210.

‡ Farey on Steam Engines, p. 371.

§ Dodd on Steam Engines, p. 216.

a tension of one, two, three, ten or more atmospheres. By using these results, we can know what temperature the steam must not surpass after we have fixed on the pressure. If we then cover an opening in the boiler with a plate made of an alloy of lead, tin and bismuth, in proportions such that the alloy will melt at the limit of the temperature fixed upon beforehand, this temperature can never be exceeded, for on reaching it, the plate melts and gives vent to the steam.

"In France, a royal ordinance requires that every boiler shall be provided with two fusible plates of unequal sizes. The fusing point of the smaller is 10° centigrade (18° of Fahr.) above the temperature of steam having an elasticity equal to that which the steam to be used in the engines, should have. The second plate fuses at 10° (18° Fahr.) above the first.

"The plate does not approach the point of fusion without being softened: it is therefore to be feared that it might give way under a tension much less than that which produces its fusion. At the outset this actually did take place, but the difficulty has been obviated, by covering the plate with a wire gauze with small meshes, before it is fixed by bolts to the aperture which it is to close. Even now parts of the plates yield partially, swelling out in different places as the fusing point approaches, but experience has shown that it is only very near to this point that the metal yields entirely, opening a free passage to the steam. When the fusible plate has been melted, all the steam escapes through the opening which it closed, and it may take some time to replace it, to fill anew the boiler, and to heat the water, during which the engine stands still. In certain cases, this sudden absence of the moving powers might occasion serious accidents. This is a real and a great difficulty,* and perhaps is the reason why our neighbours (the English) have not adopted the fusible valve, but give a preference to the ordinary safety valve, which never opens, except when the elasticity of the steam within has passed a certain limit, previously fixed by the engineer, and falls, closing the aperture, when the elasticity has returned within this limit without the moving power failing entirely."†

M. Gualtier directs, that "these fusible disks should be composed in such proportions, that they will melt at a temperature but little higher than that at which the steam boiler of the machine ordinarily works. 2. That they should be placed in a proper situation, as it is known that in different points of the surface of the boiler, the temperature is not perfectly equal, and that a disk which would melt at one point will remain solid in another; the best position for them is over the fire place."‡

10. *Dampers.* To enable the fireman to have full command of the fire, to increase it when necessary, and to diminish it when too intense, and more steam is generated than is wanted, *dampers*, at the junction of the flues with the chimney, should never be omitted. These dampers should be self-acting, and be connected with the safety-valve as proposed by the Chevalier Edelcrantz; for nothing should be left to the vigilance of the fireman.§ Mr. Renwick suggests that "there should be another, to be worked by hand as occasion may require; and in order to place the fuel under the control of the firemen, the passage by which the air is admitted to the ash-pit ought also to be capable of being opened and shut at pleasure. Doors and valves for this purpose should therefore be provided, and the apparatus is called a Register."‖ Too many precautions to prevent the loss of lives cannot be adopted.

11. *Attention to the working of the Engine.* As it has been mentioned in the preceding pages, that just before an explosion has taken place, the engine has been observed to labour, or work more slowly, the engineer should bear this fact in mind, and prevent the calamity by timely attention. The cause of this slow motion has already been explained, p. 443. The means of prevention therefore is, to avoid opening the safety valve, or steam guage cock, which would cause the water to rise suddenly, and come in contact with the over-heated metal; to withdraw the fire as speedily as possible; to check the draught of the chimney by the damper, and to avoid a sudden change of position of the boat.

12. *Strengthening the partitions between the Boilers and Passengers.* A great means of security to passengers in case of an explosion, is to strengthen the partition between the boilers and the passengers, and to weaken the other parts of the enclosure, so that the steam should issue out at the place of least resistance.¶ Professor Silliman recommends that this bulwark of timber should be made so strong as to resist not only water and steam, but also the fragments that may be projected, or even the entire boiler should it be thrown from its bed;** that two boilers be placed on the guards of the vessel over the water, and that the side next to it should be open. This bulwark has been many years adopted in the English steam packets.††

13. *Tow-boats.* The only infallible means of preventing danger from explosions remains to be mentioned.

As it has happened, that explosions have occurred on board of boats, when, according to the declaration of those concerned in their management, they could not be ascribed to any of the causes before enumerated, and as similar cases may again take place, the ONLY CERTAIN MEANS to insure perfect safety to travellers, is to place the machinery in one boat, and to tow another containing the passengers. This was one of the measures which the unfortunate Fitch intended to adopt, if he succeeded with his boat, and mentions it in his manuscripts bequeathed to the library company of Philadelphia. It has recently been again proposed by Mr. J. R. Sullivan, and demands the serious attention of the proprietors of steam-boats. The attempt was indeed made three years since by the owners of the Commerce, on the North River, but,

* But not so great an inconvenience as being blown up, a misfortune which these fusible plates would prevent.

¶ This was recommended by a committee of gentlemen who were applied to by the councils of Philadelphia, on the subject of the prevention of explosions, in the year 1817.

** American Journal of Science, 1830. No bulwark would be able to resist the entire boiler, or a large portion of it.

†† Dodd on Steam Engines, p 214. London, 1818.

owing to the deficient power her speed was much slower than that of other boats, and therefore not much patronized. Mr. S. proposes to use the strongest form of boiler, and to have the follower of a light sharp construction, with one deck, that the resistance of the water might be small. Professor Silliman remarks that "there seems to be no objection to the plan of any weight, upon waters generally smooth. The excessive speed now aimed at is of no importance; no reasonable man will be dissatisfied if (sleeping and waking) he can go ten miles an hour. This degree of speed, and probably more, is attainable in tow boats." He adds this important consideration; "the proprietors of steam-boats must answer to their country and to God, if they neglect any practicable means of defending their fellow creatures from the most awful calamity to which the confiding traveller is exposed." But this argument will have little avail with them; the concluding one used by him will have much effect, viz. that "the *first boat which is ascertained to afford absolute security will be a fortune to its proprietors.*"*

On the Economy of using high pressure Engines acting expansively, and condensing.

In p. 431, it was intimated that Mr. Evans overrated the economy in fuel from the use of his high-pressure engines. His deductions were the result of experiments recorded in the seventeenth vol. of the Ency. Britannica. But later experiments by the French Academicians, Arago, Dulong, &c., give a different result. According to those, an increase of 30° of Fahrenheit does not double the pressure of steam. Even by the experiments of Dalton, made long since, 40° of Fahr. are required to produce this pressure. The French committee prove that the doubling of the pressure at high temperature, requires a greater augmentation of heat than at a lower temperature. Thus, while an augmentation of 21° of the Centigrade therm.=38°.5 of Fahr. increases the pressure from one to two atmospheres, it requires an addition of 31½° Cent.=56°.7 Fahr. of temperature to augment the pressure from 8 to 16 atmospheres: and to raise the pressure from 12 atmospheres to 24, the increase of temperature necessary is 61°.5 Fahr., and if we may rely on their formula† given for computing the pressures at temperatures above 24 atmospheres, it will require an increase of 71°.28 Fahr. to the temperature to augment the pressure from 25 to 50 atmospheres.

The following little table of differences, by Professor Walter R. Johnson, is derived entirely from that part of the table of the French Academicians constructed from their experiments, and shows that the fourth stage of doubling pressure, viz. from 12 to 24 atmospheres, the increase of temperature is $\frac{3}{2}$ of what it is at first, or from 1½ to 3 atmospheres.

Difference of pressure in atmosphere.	Difference Cent.	Difference Fahr.
1½ to 3	22.9	41
3 to 6	25.7	46.2
6 to 12	29.8	53.8
12 to 24	34.2	61.5

Thus although the general position of Mr. Evans is true, viz. that while the temperature is increased arithmetically, the elastic power of the steam is increased geometrically: yet the particular law of that increase, as laid down by Mr. Evans, is not sustained.

In conformity with this general position, Mr. Perkins, p. 396, considers the observation which he has made upon elastic steam generated with enormous heat, as leading to the following result: *That* while the temperature rises in an arithmetical ratio, the expansive force will be that of an increasing ratio, and the increment of fuel will be a decreasing ratio.

Mr. Henwood, an advocate of the low pressure engine, states‡ that the average duty of Mr. Watts' engines was about 25 millions lbs. lifted with one bushel of coals, and according to Mr. Farey, all the water works in London are now served by Watt's engines, working low pressure steam, acting expansively in one cylinder, and the performance of the best of them is about 25 millions. Mr. John Taylor states, that according to the official monthly report of the Mine agents in Cornwall, one engine (high pressure) of Mr Woolf at Wheal Towan, raised in 1828, on an average 77,290,000; in 1829, it was 76,235,397 lbs. with one bushel of coals. During an experiment by Mr. Rennie with the same engine, it raised 92,327,000 lbs. with the same quantity of fuel:§ and Sir H. Davy states in the Trans. of the Royal Soc. for 1827 and 1829, that this engine performed a duty in the whole month of December 1829, exceeding the average of 17 engines on Mr. Watt's construction in 1798, by a proportion of nearly 4 to 1. Finally, Mr. Farey gave his opinion before the committee of the House of Commons, that "the difference in cost, between the quantity of coals consumed by the engines now in use (which are all on Mr. Woolf's system), and by an equal force of engines such as were in use before he went to Cornwall, in 1813, would absorb the profit of all the deep mining that is now carried on in Cornwall." Nothing,

* Silliman's Journal, 1830.

† These calculations must, however, be received with some qualification. Biot, in speaking of results from other data, says, "This table, calculated after the formulæ deduced from experiments of Dalton, has not been carried beyond 135°, because it would then become defective. Indeed similar formulæ are never more than approximations, in which are comprehended only the terms, which are sensible, with the experiments, that are compared. We must not then carry them to limits beyond those which these observations would include, since the neglected terms would then acquire an influence which had not been found to belong to them, while their absence would occasion great errors.

"For example, if it were wished to carry the formula to 200°, the elastic force would be seen to cease augmenting, and even begin to diminish. But that means no more than in making the proper application of the first observations, we have neglected some terms which should have been regarded in making calculations to such high degrees. This defect could be remedied, if we possessed some data relating to the tensions of the steam observed at those degrees, for then could be applied to them the formula in adding a term in n^4, which would be insensible at lower degrees. But from the want of such observations, we have limited the formula to the extent allowed by the experiments of Mr. Dalton." Biot. Traite de Physique, vol. i. p. 530.

‡ Philos. Mag. 1830, p. 324. § Do. pp. 425, 430.

it would seem, can more fully demonstrate the superior power and economy of high pressure engines.

Mr. Thomas Lean, the professional inspector of steam engines in Cornwall, stated to a committee of the House of Commons, of England, in 1817, that "high pressure engines save at least two-fifths of the whole consumption of coals in Cornwall."

In p. 397 the discovery that steam at a very high temperature will not scald, is attributed (but erroneously) to Mr. Jacob Perkins, for it was first accidentally made (in this country) sixteen or seventeen years since, at the Fairmount Waterworks, on Schuylkill, by a workman named Kissick, who had the care of the high pressure engine which was used at the time, to raise water from the river for the supply of the city; and who has at present the charge of the powerful water wheels erected for the same purpose. Having opened the guage cock for the water, to ascertain the height of it in the boiler, he received a stream of high steam in his face, and thought himself ruined, but in a minute or two he was agreeably disappointed, on finding no inconvenience from it, except the trickling down his face and breast, of the water from the condensed steam.

The fact being thus ascertained, the workmen of Mr. Evans made no difficulty about caulking boilers, while high steam from them was pouring out on their faces and hands, through leaks. A short time after the first discovery, an occurrence similar to Kissick's happened to Mr. Eckfeldt, at the mint. The aperture of the guage-cock of the high-pressure engine, used for driving the machinery of the mint, was originally at the bottom, but in consequence of a deposition from the water in the boiler, it became closed. The place of the aperture was therefore changed to the front, in order that a wire might be easily inserted to clear the passage when necessary. Some time after, the cock was turned, and Mr. Eckfeldt, who was standing about two feet from it, received the full blast of the steam directly in his face: at the moment he was much alarmed, but in turning round, he was agreeably surprised to find he was not scalded. The writer made the experiments in the presence of Mr. Eckfeldt, on the 20th of April, 1831, while the engine was at work, with a pressure of nearly 150 lbs. to the inch, the usual extent to which it carried. He held his open hand first at the distance of 18 inches from the cock, while the steam was rushing with tremendous force from the aperture in the cock, and finding it little more than warm, he placed it within nine inches of the cock, and even then the sensation excited was not more than that of an agreeable warmth. Oliver Evans mentioned the fact, in a hand bill, on the 28th of October, 1817, that high steam does not scald, see p. 431: this was before Mr. Perkins left Philadelphia, which he did in May 1819. Mr Brunton, an experienced English engineer, gave another proof of the fact to the committee of the House of Commons, in 1817,* and Mr. Vivian also said, on the same occasion, that "the steam from low pressure scalds much worse than the steam from high pressure."†

Mr. Perkins, however, confirmed the fact in England, by a set of ingenious experiments, as related in p. 397, and explains it thus: "I have frequently observed, that when the stop cock of a high-pressure boiler was opened, whether at the water or steam cocks, the *temperature was lowered in proportion to the height of the steam.* He ascribes the phenomenon to the great force and rapidity of motion of the steam causing the atmospheric air to be driven before it, evidently tending to produce a partial vacuum, to which the surrounding atmosphere would rush in, and diminish." This explanation, however, is only in part true, because the diminution of temperature of the steam is observed in tubes when the atmospheric air is excluded. A very neat set of experiments by Mr. Ewart, of Liverpool, show that the reduction of the temperature of steam, is owing to the great expansion of it, and the recovery of its capacity for heat. He ascertained that the heat of the boiler was 292°, and that of the issuing steam 185°:‡ thus confirming a well-known law, viz: the diminution of the capacities of bodies for heat when condensed, and their increased capacity for it when expanded. This law equally applies to fluids in an aeriform state, and hence the temperature of steam condensed in a boiler is raised, and lowered if allowed to escape and expand.

STEAM CARRIAGE. The idea of driving carriages by means of mechanical power is of considerable antiquity, and in the older works on mechanics, we meet with drawings of carriages impelled by the action of wind upon sails, and of others driven by the action of the feet of men in the carriage. Maillard's chaise driven by winches, Brodie's self-driving chaise, and Maillard's chaise with an artificial horse, may be enumerated among carriages driven by mechanical power.

Dr. Robison seems to have first suggested the idea of driving carriages by steam, and it appears that Mr. Symington of Falkirk, so early as 1787, was occupied with a plan of applying the steam engine to carriages. These proposals, however, were never carried into effect, so that the real merit of introducing the steam carriage belongs to Messrs. Trevithick and Vivian, who invented their high pressure engine with the express view of using it in propelling carriages on railways. Although their patent was taken out in 1802, yet it was not till 1805 that it was actually applied in the experiment of moving carriages on a railway at Merthyr Tydvil, when trials were made at different times, but it was not till 1811 that the first steam carriage was actually used for practical purposes. This was done by Mr. Blinkensop (proprietor of the Middleton coal works, which supply the town of Leeds with coal), who introduced steam for the purpose of conveying coal wagons along his rail-roads. In the steam carriage which Mr. Blinkensop used, the boiler was supported by four wheels without teeth; but it was driven by a crank connected with the piston, which needed other two wheels in the centre of the carriage having teeth in their circumference. These teeth engaged in teeth on the rail-road, and in this manner the carriage was moved along followed by a train of *thirty* coal wagons.

In the year 1816 Messrs. Losh and Stephenson of Newcastle took out a patent for improvements in steam carriages and railways, which we have represented in Plate DXI. Figs. 1. 2, 3 and 4. Fig. 1. is a section of the steam carriage, Fig. 2. is a view of it dragging after it the carriage EF, containing coals at E and water at F, and the first wagon G of the train. The steam-engine shown at AB has two cylinders, whose pistons T, B, drive the crank rods AC, BD, which give a rotatory motion to the two wheels C, D, to whose axles they are fixed. The two opposite wheels, which are not seen in the figure, are driven by similar rods. The circumferences of the wheels take hold of the rail rod RR merely by friction. The middle pair of wheels receive their motion from the other two pair by means of a chain passing over two rag wheels *m*, *n*, placed in the centre of each axle as seen at *c*, Fig. 5. This chain drives a third rag wheel *c*, and thus drives the middle pair of wheels. In the steam-carriage used by Mr. Blinkensop, the engine was supported directly by the axles, but Messrs. Losh and Stephenson connect the boiler with the axle by means of *six* floating pistons *b*, *b*, &c, movable within cylinders *a*, *a*, *a*, *a*, into which the steam and the water is allowed to enter. These cylinders are best seen in Fig. 1. where *b*, *b*, are the floating pistons connected with wrought iron rods below; the ends of which rest upon the bearing brasses of the axles of the wheels C, D. These pistons press equally on all the axles, and thus make each wheel bear with equal force on the rail-rod R, R, and act upon them with equal friction, even though the rails should not be all in the same plane. This effect is produced in consequence of the bearing brasses having a certain degree of play in a groove or slide in a vertical direction; and as they carry the axles and wheels along with them, they force the wheels to accommodate themselves to the irregularities of the road. A steady motion is thus obtained, and shocks are better prevented than if the engine rested on the finest steel springs. The construction of the rail-road and the wheels is shown in Figs. 3 and 4.

The engine used in steam-carriages is the high pressure one of Trevithick, already described and represented in Plate DIX. Fig. 4; but as this subject has now become one of national importance, we have given in Plate DXI. Fig. 5, a drawing of one of the most approved steam-carriages with its engine after Mr. Tredgold.

Fig. 5 is a side elevation, and Fig. 6, a vertical section of this carriage, the same letters indicating the same parts in each. From the cylindrical boiler A, surrounded with the fire and flues, the steam passes into two large cylindrical reservoirs of steam H, H′, of the same diameter. In these reservoirs are placed the engine cylinders G, G′. The parts H, are a reservoir of water not exposed to the pressure of the steam, but warmed by the flues and chimney so as to be heated previous to its being pumped into the boiler. For distributing the heat of the fuel over a large surface there are two fire places with fire doors at B, B′, which are fed with coals by hoppers from the boxes D, D′, the doors being used only to clear the bars. The flues meet at the middle, the one from the fire B rising at F, Fig. 6, passing along the upper surface of the cylinder A round H at M, then round the end of the boiler, and returning on the opposite side to ascend the chimney in the division E′. The other flue proceeds in a similar manner but in an opposite course, and ascends at E; there are two apertures beneath each ash-pit C, C′, for admitting air, and both of them should be provided with registers, so that those may be open, which either face a strong wind, or the direction of the motion of the carriage when there is not sufficient wind. For the same reason the top of the chimney should have two mouths to assist the draught. The engine and boiler rest upon a frame supported by the axis; but in order to prevent the carriage from resting on three wheels, four spiral springs may be fixed on the boxes LL, and the cross heads must be connected to the piston rods, and all the bearings must be formed so as to accommodate the parts to the sinking of one of the wheels. The pipe K carries the waste steam to the chimney, and there should be two safety valves, one locked in a box at J, and the other at J′ for the use of the engine man.

In the year 1824, our late ingenious countryman Mr. David Gordon, to whom the arts are indebted for the invention of the portable gas lamp, took out a patent for improvements in the construction of steam-carriages. His improvements relate to the machinery by which the power of the engine is to be applied to the ground, and the principal part of the contrivance consists of rods or propellers jointed to cranks situated at different angles upon the same axis, so that the extremities or feet of the propellers will act upon the ground in succession at a time when they are moving with the greatest velocity, or nearly so. The under surfaces of the feet of the propellers are curved, being described by a circle of about the same radius as the radius of the cranks which put them in motion, in order that the feet may accommodate themselves to the ground, particularly in the act of turning. Bristles, whalebone, or other pliable materials are fixed on the under surfaces of the curved feet of the propellers, as a substance to come into contact with the ground and take sufficient hold of it. During winter, when the ground is frozen, it is proposed to furnish the under surfaces of the feet with steel points projecting sufficiently to seize the ground. Notwithstanding the ingenuity of these views, it is obvious that nothing can be gained by substituting feet for wheels, and that much power must be lost by the very action of the mechanism employed.

Great difficulties have yet to be overcome before steam-carriages can be used on common roads. On level and well formed lines there is no difficulty whatever, and the present steam carriages are perfectly capable of performing useful work under such circumstances; but unless some great invention is made by which we can increase the power of steam engines, without greatly increasing their weight, we can see no prospect of their being advantageously employed in any other way than upon rail-roads.

For farther information on this subject, see the works referred to in the two preceding articles.

From the statement given by Oliver Evans, p. 427, it is certain that he proposed to drive wagons by steam, in the year 1786, and his experiment with the scow, p. 429, shows that it is possible to do so. The writer, and a thousand others now alive, witnessed this gratifying spectacle. From the commencement of his speculations on the subject of steam, he looked forward to applying it as a moving power to carriages for the transportation of passengers and merchandize; and he never lost sight of this great object. He only wanted the assistance of a wealthy friend to enable him to succeed; but it was his lot not to find any one, who, while he had the means, had so much confidence in the ultimate success of the project, as to risk his capital in making the experiment. Had such a bold spirit been found, the state of Pennsylvania would have had the immortal honor of seeing the first trial with steam carriages, and of anticipating the example set to the world by the British engineers, and which has conferred such high and lasting honor upon them for their success.

In the Steam Engineer's Guide, p. 54, may be seen the proposition to the Philadelphia and Lancaster turnpike company, in Sept. 1804, which is referred to by Evans in p. 429, "to build a steam wagon, which should transport 100 barrels of flour 50 miles in 24 hours;" and gives the calculations and items of expense attending its first cost and maintenance, and those of common wagons, five of which, with five horses each, are required to perform the same work. He makes it clear, that the profits of the steam wagon on the journey, would be \$ 104, or \$ 52 per day, while that of the wagon is \$ 3 66 per day, or \$18 33 for the whole route; and adds the important consideration, that the steam wagon would roll and mend the roads, while the horse wagons cut them up. He concludes by observing, "I have no doubt, but that my engines will propel boats against the current of the Mississippi, and wagons on turnpike roads with great profit, and now call upon those whose interest it is, to carry the invention into effect." This call was unattended to.

From a publication in the Philadelphia Aurora of December 10, 1813, it appears that Mr. Evans made another proposition on the 8th of the preceding October (which cannot be found) to "establish a line between Philadelphia and New York, for the transportation of heavy produce, merchandize, and passengers, on *carriages to be drawn by steam engines*, on railways, or smooth roads." In this last paper he gives partially the details of the scheme, and concludes thus: "I renew my proposition, viz: as soon as either of these plans shall be adopted, after having made the necessary experiments to prove the principles, and having obtained the necessary legislative protection and patronage, I am willing to take of the stock five hundred dollars per mile, to the distance of fifty or sixty miles, payable in steam carriages, or steam engines invented by me for the purpose forty years ago; and will warrant them to answer the purpose, to the satisfaction of the stockholders: and even to make steam stages to run twelve or fifteen miles per hour, or take back the engines at my own expense, if required." This second offer met with the same fate that had attended the first. It is somewhat singular, and much to be regretted, that at this very time (1813), when such immense sums were expended in manufacturing, and often by persons totally ignorant of the business, and \$1500 were given readily for a pair of merino sheep, that none could be induced to engage with him in prosecuting the business he proposed, even after he had evinced the probability of success by his first attempt with the scow (see p. 429), through the streets of Philadelphia to the Schuylkill —a success, which, from the British experiments, we have well-grounded reason to believe would certainly have taken place. Had his valuable life been prolonged to the present day, when the whole country is engaged with rail-road projects, capital in abundance would have been at his offer, and he might have seen several of his predictions verified, to the fullest extent.*

* Predictions by Oliver Evans in 1813:

1 The time will come, when people will travel in stages moved by steam engines, from one city to another, almost as fast as birds fly, fifteen or twenty miles an hour.

2. A carriage will set out from Washington in the morning, the passengers will breakfast at Baltimore; dine at Philadelphia, and sup at New York the same day.

To accomplish this, two sets of rail ways will be laid, travelled by night as well as by day, and the passengers will sleep in these stages as comfortably as they now do in steam stage-boats.

3 A steam engine, consuming from a quarter to a half a cord of wood, will drive a carriage 180 miles in twelve hours, with twenty or thirty passengers, and will not consume six gallons of water.

4. These engines will drive boats ten or twelve miles per hour, and there will be many hundred steam boats on the Mississippi,* and other western waters, as *prophesied thirty years ago.*

Posterity will not be able to discover why the Legislatures, or Congress, did not grant the inventor such protection as might have enabled him to put in operation these great improvements sooner; he having asked neither money, nor a monopoly of any existing thing.

---

* Mr. Evans lived to know, that in 1813 there were three steam boats on the Mississippi; and recent information gives the number 160' most of which have been built and completed at Pittsburg and Cincinnati.

In the Franklin Journal, Vol. I, p. 187, is a list of the numerous patents granted in England for steam carriages, all of which were taken out subsequently to the first proposition of Oliver Evans.

The following statements show in part, how well founded the predictions of the ingenious and enthusiastic inventor were. From what has been done at Baltimore, and Manchester in England, on rail roads, there can be no doubt of the possibility of accomplishing every thing predicted by him.

From the Baltimore American, of March 21, 1831.

The experiment of the transportation of *two hundred barrels of flour*, with *a single horse*, was made on the rail-road on Saturday with the most triumphant success. The flour was deposited in a train of eight cars, and made, together with the cars and the passengers who rode on them, an entire load of 30 tons; viz:

200 barrels of flour,	20 tons
8 cars,	8 "
30 Passengers,	2 "
	30 tons.

The train was drawn by one horse from Ellicot's Mills to the relay-house, six and a half miles, in forty-six minutes. The horse was then changed, and the train having set out, reached the depot on Pratt Street, in sixty-nine minutes—thus accomplishing the thirteen miles in one hour and fifty-five minutes, or at the rate of 6 and three fourths of a mile an hour. The road between the relay-house and the depot is a perfect level, except at the three deep excavations, where an elevation of seventeen to twenty feet per mile, has been resorted to, for the purpose of drainage. The horse, except at the points just alluded to, brought the train along at a moderate trot, and apparently without any extraordinary labour; he is not remarkable, and was not selected, for any peculiar powers of draft, and had performed a regular trip outwards on the morning of Saturday. It is, we believe, only about a week ago that we noticed the fact of the transportation of seventy-five barrels of flour, by one horse, as a circumstance worthy of remark in comparison with the number of horses required for the conveyance of a load of a few barrels over a turnpike road. The experiment detailed above shows, that on Saturday a single horse drew three times as large a load; and there is no doubt that horses could be found, who could with the same ease transport a load of three hundred barrels.

The following statement was furnished by a gentleman who kept the time.*

From the mills to the relay-house	46 min.
From the relay-house to the depot	69
	h. 1 55 m.

The first mile was performed in	7 m.	20 s.
Second do.	7	20
Third do.	7	20
Fourth do.	6	00
Fifth do.	6	00
Sixth do.	8	30
Seventh do.	8	00
Eighth do.	9	00
Ninth do.	10	00
Tenth do.	12	00

No account was kept of the last three miles.†

MEASE.

[*Errata.*—Page 440, line 21, for 1781, read 1787. In some copies, p. 455, the heading of the section should read, "On the economy of using high pressure engines, acting expansively, and condensing."]

STEAM GUNS. While Mr. Perkins was making experiments with the high pressure steam of his generator, he observed that all metallic substances were projected from the tube of the stop cock with very great velocity. The idea then occurred to him, that with a gun barrel properly constructed, bullets might be discharged with precision and great force: and upon constructing such a barrel, his expectations were realized. By placing musket balls in a hopper from which they fell in succession into the gun barrel, he was able to project two hundred and forty balls per minute, with a velocity greater than that of gunpowder. An ounce ball was discharged from a musket with the ordinary field charge against an iron target, while another similar ball was discharged against the same target from a six feet steam barrel, impelled by steam of forty atmospheres. The distance was the same in both cases; but it was found that the ball discharged by steam was much more flattened than that discharged by gunpowder. In another series of experiments Mr. Perkins projected balls with a force of one hundred and ten atmospheres; he found that they perforated a block of wood through a greater thickness than those impelled by gunpowder. He succeeded in throwing a shower of balls at the rate of one thousand per minute. Mr. Perkins avers that he could keep up the same force of steam without intermission for twenty-four hours, or any unlimited time. A very important result of these experiments is said to be, that *one pound weight of coal* is capable of producing a quantity of steam equal in force to *five pounds weight of gunpowder*. These experiments were the foundation of Mr. Perkins's patent in 1823, for an improved method of throwing shells and other projectiles by steam. Some farther details respecting the steam-gun will be found in our article SCIENCE, *Curiosities in.* Vol. XVI. p. 622.

[For an account of Perkins' experiments with his steam-gun, see Franklin Journal, Vol. I. p. 79, and Vol. III. p. 411.]

STEAM ROCKET, PERKINS. See SCIENCE, *Curiosities in.* Vol. XVI. p. 622.

* Baltimore Gazette, March 21, 1831.

† A late report of the directors of the Liverpool and Manchester Rail-way states, that on the 25th of February 1831, the Samson locomotive engine drew 30 wagons, carrying 107 tons of merchandize, the gross weight conveyed (besides the engine and tender) being 150 tons. She was assisted up the inclined plane by three other engines, and without further aid proceeded to Manchester, where she arrived with her train in two hours and thirty-five minutes from the time of starting:—distance 30 miles. Passengers are conveyed on the cars in one hour and a half, and even in one hour and a quarter.

STEAM DRYING MACHINE.—The mode of drying linen and other cloths by steam was first suggested by Mr. Watt, who, so early as January 1781, contrived a machine of this purpose for his relation, Mr. James Macgregor, Clober, near Glasgow. This machine was erected, but no description of the invention was ever published.

A few years before his death Mr. Watt put into the hands of Dr. Brewster several MSS. and drawings of some of his minor inventions, for the purpose of publication, either in this work or in his Journal of Science, and one of them was his account of the steam-drying machine. The following description and relative engravings are copied exactly from the MSS. and drawings of Mr. Watt.

Fig. 7. of Plate DXI. is an end view of the machine, the frame for supporting it being omitted.

A A the ends of three copper cylinders.

H H two rollers to wind the cloth on and off.

Fig. 8. is a side view. A A are two of the copper cylinders 2 feet diameter, and 4 feet long.

B B two conical bell-metal sockets fitted steam tight to a hollow axis.

C C two copper steam pipes from the boiler.

D boiler two feet diameter.

E a conical valve $1\frac{1}{2}$ inch diameter to discharge the spare steam.

F a funnel and pipe to supply the boiler with water.

G two small cocks placed 2 inches asunder, by opening which it is known if the boiler be too full or too empty.

Fig. 9. and 10. views of the box which returns the condensed water to the hollow axis. It consists of a circular box of copper B B, 4 inches deep, divided into 4 divisions. In two of the divisions are holes D D, which take in the water when they are at the bottom; and as the cylinder turns round, transmit it to the holes. E E in the hollow axis C C, by which it is returned through the steam pipe to the boiler, being directed by the partition G in the axis. In the other two divisions are holes F F to admit the ingress and egress of steam from the cylinder to the box. Mr. Watt was of opinion that the hollow tube C might consist of two separate tubes, opening into each other at their extremities.

STEATITE. See Mineralogy, *Index*.

Steatite is a kind of saponaceous stone, which is sometimes found of a white colour, at others grey or green, and but rarely red or yellow. Its specific gravity varies from 2.60 to 2.66.

This substance is composed of a mixture of silex, alumine, magnesia, oxide of iron, and water; but it differs according to the localities in which it is found. It is very common in Germany, and in Cornwall; and we have no doubt that it may also be found in the western parts of France.

As steatite is not fusible excepting at a very high temperature, and as it can be worked with the greatest facility, so it forms excellent crucibles, which harden in the fire, and which litharge penetrates with great difficulty. It also serves as a facing to protect moulds for casting iron, and other metals.

M. Viscot, of Liege, made a great number of experiments to prove that this substance might be employed by the lapidaries. He formed cameos with it, to which he gave a fine polish, after exposing it to the action of the fire; and it becomes so hard, as to give sparks like flint, when struck upon hardened steel.

By polishing it, he gave the appearance of agate, and even obtained some pieces which perfectly resembled the onyx; but this appearance was quickly destroyed by the fire, and he found it impossible to restore it.

Having a great affinity with glass, the steatite, when reduced to a very fine powder, and mixed with the colours, becomes exceedingly convenient in painting upon it. It is also used as a kind of sympathetic crayon, for drawing or writing with upon glass, and on which it leaves no apparent trace, after the drawing or writing has been wiped over with a woollen cloth. However, the marks are rendered instantly visible, by breathing upon them; but they disappear anew, when the glass becomes dry.

The embroiderers and tailors prefer steatite to chalk, to make traces with; as they are more durable, and do not affect the colours of their cloth.

As steatite has the property of combining with oil or grease, so it enters into the composition of the greater part of the balls, which are used for cleaning silks and woollen cloths from oil or grease spots. It also serves as a basis, in the preparation of certain colours for painting with.

It is employed to give a fine polish to marble, serpentine, and other gypseous stones. Mixed with oil, it is used to polish glass and metallic mirrors.

If the surface of newly prepared leather be sprinkled over with it; and if, when it has become dry, it be rubbed with a piece of horn, it will give the leather a fine gloss.

Steatite is also employed to glaze paper, upon the surface of which it is sprinkled, when it is reduced to a very fine powder; or, which is much better, when mixed with the colouring materials. To glaze the paper, it must be rubbed over with a hard brush.

The powder of steatite, owing to its unctuosity, is one of the substances employed in lessening the friction of screws, toothed wheels, and other metallic contacts.

Steatite is a mineral, which belongs to the primary or secondary formations. It often constitutes beds of great extent, but when pure, it usually forms lumps of greater or less magnitude. That variety of it termed Venice talc, abounds in the Tyrol and the Valteline. The Briancon and the Spanish chalks are found, the one in the Alps of Dauphiny, near Briancon, and the other in the mountains of Arragon. The Venice talc affords a powder, which renders the skin smooth and shining, and is employed as a cosmetic. The lard stone is also another kind of graphic talc, and is used in China, to form small grotesque figures.

Fat, and fixed oils, have long been used to lessen friction in machinery. But their bad properties, and the ill scents of these matters, ought to induce us to abandon their employment, and to substitute others for them. And we may likewise add, that the emanations which they diffuse in the workshops or mills, are frequently inconvenient; and it would, therefore, be much better to sell them to the manufacturers of oil gas. Plumbago, or the carburet of iron, has been successfully used for diminishing friction in machinery; but this material is too rare and costly to be ordinarily used. There are, however, other unctuous minerals to which we may recur, and amongst these, steatite seems to hold the first rank.

The citizens of the United States of North America, who cultivate with success the employment of machinery, as we may judge from their numerous steam boats and other machines, both for naval and other purposes, appear to be the first persons who have employed steatite in the large way. It is not, however, used alone, but mixed with a small quantity of oil, suet, or tar. They commence by reducing it to a very fine powder, and then mixing or triturating it with the material intended to render it more unctuous. The first experiments on using it were made at Lowell, in the state of Massachusetts; and the coachmen and wagoners have found it highly beneficial.

Mr. Moody, superintendent of the great iron works established upon the mill dam near Boston, has afforded us means of estimating the advantage to be derived from the use of this new mixture. In one of the works is a wheel of great size and weight, which makes from 75 to 100 revolutions per minute, and turns upon necks or gudgeons of five inches in diameter. It has moved with this speed during three, and sometimes five, weeks together, without renewing the lubrication of the gudgeons. Nevertheless, Mr. Moody thinks it best to renew it oftener. The machinery, of which this great wheel forms a part, manufactures about 200,000 pounds of iron per month.

It is to chance, that we are indebted to the discovery of this valuable employment of steatite, the use of which is now continually extending in the United States; and will also, no doubt, be speedily adopted in Europe.—*De Moléon's Recuiel Industriel.*

Additions by the Editor of the Technological Repository.—Steatite is also used in the United States to line furnaces with; a type founding machine, sent from thence, and patented here, had a furnace of this kind. And the Editor lately saw, in the hands of Mr. Lemuel Wellman Wright, engineer, a cubic mass of it, a foot square, and which had been sent to him by an American friend. He had sawn off a portion of this block, and exposed it to the heat of his fire for several hours; after which it had assumed the appearance of a mass of *mica*, still, however, cohering together. The Chinese also make small portable furnaces of steatite.

The *lapis ollaris*, or potstone, is also another variety of steatite. Bishop Burnet gives the following account, in his travels, of the mode of using it in Switzerland. "There are a sort of pots, made of stone, which are used, not only in all the kitchens here, but also in those of almost all Lombardy, called *Lavege*. The stone feels oily and scaly, so that a scale adheres to the finger of any one that touches it, and it is somewhat of the nature of slate. There are but three mines of it known in these parts; one near Chavennes; another in the Valteline; and the third in the Grisons; but the first is much the best. They generally cut it round in the mine, in masses of about a foot and a half in diameter, and a foot and a quarter in thickness; and they work it into shape in a mill, where the blocks of stone are driven about by a wheel, set agoing by water; and which is so ordered, that he who manages it, turns the outside of the stone, first, till it is quite smooth; and then separates one pot after another, by small and hooked chisels, by which means he makes a nest of pots, one within another; the outward and biggest one, being as large as an ordinary cooking pot, and the inward one, no larger than a common pipkin. These pots they arm with hooks and circles of brass; and so they are used by them in their kitchens. One of these pots heats and boils sooner than any metal pot; and yet the bottom is twice as thick as that of a metal one. It never cracks by the heat, nor gives any sort of taste to the liquor that is boiled in it; but if it falls to the ground, it breaks, as it is very brittle; nevertheless, it is soon repaired again; for they piece their broken pots so close, by sewing the broken parts together with iron wire, which completely fills the holes they make to receive it, that there is no breach made, although no cement is used. The passage to the mine is very inconvenient, for they must creep for near half a mile through a rock, which is so hard, that the passage is made not above three feet high; and so that those who draw out the stones, creep all along upon their belly, having a candle fastened to their forehead, and the stone laid upon a sort of cushion, made for it upon their hips. The stones are commonly two hundred weight."

STEEL is the name of a well known metal, consisting of iron combined with carbon, or a carburet of iron. When small pieces of fine malleable iron, surrounded with powdered charcoal, are exposed for eight or ten hours to a strong red heat, the iron is converted into steel, and is then found to have united with the 150th part of its own weight of carbon. The following are the general properties of this important metal:

Steel unites with the malleability of bar iron the fusibility of cast iron, and if immersed in a cold fluid when hot, or otherwise suddenly cooled, it becomes intensely hard, sonorous, and elastic,—these properties varying according to the heat of the steel, and the temperature of the fluid, or other substance in which it is cooled. In consequence of these properties, steel is of great use in the arts for all sorts of cutting instruments, for springs, and even for musical instruments. In general, steel is brittle, resists the file, yields sparks with flint, and retains magnetism for a very long time. The hardness, in virtue of which it possesses these properties, disappears after ignition and slow cooling. At a red heat it is malleable, but less so at a white heat. It is capable of being beat out into thinner plates than iron. It melts at 150° of Wedgewood. Its specific gravity varies from 7.78 to 7.84. By repeated ignition under exposure to the air and hammering, steel again becomes wrought iron. According to Kirwan, steel may be easily distinguished from iron by letting fall a drop of diluted nitric or muriatic acid on a plate of steel. When washed off after lying a few moments, a black spot is left, whereas on iron with nitric acid the colour of the spot is whitish green. The cause of the black spot is, that a portion of the iron is dissolved, while the carbon is left.

There are three different kinds of steel, which are obtained by three different processes. 1st, *Natural steel*; 2d, *Steel of cementation*; and 3d, *Cast steel.*

1. *Natural steel.* The *natural* or native steel of Eisenhartz in Styria, is obtained directly from the ore. The ore used is the Spathose ironstone, consisting of the carbonates of iron, manganese and lime, together with a mixture of clay, which occurs abundantly in the neighbouring hill. The fuel employed is always charcoal, and generally amounts to about one-fifth of the ore in weight. The ore is first converted into cast-iron by repeated meltings, and removals of the scoriæ, and the cast-iron thus obtained is purified in the crucible of a refinery previously lined with charcoal, particular care being taken that the carbon contained in the cast iron is not burnt away. When the natural steel is thus sufficiently purified, it is extended under the hammer, and cut into bars which are examined by their fracture, and separated into *hard steel, soft steel,* and *steely iron*, the last of which is used for pointing ploughshares, and other rough work. The other two kinds of bars are made up into packets, the hard steel being placed inside, and when drawn into bars at a lower heat than that used for iron, it becomes *natural steel.*

In this process a portion of the carbon is supposed to combine with the oxygen in the cast iron, and to escape as carbonic acid gas, while the rest of the carbon unites with the pure iron, and forms steel. In quality this steel is inferior to other kinds. It is less homogeneous, and is softer and less frangible. From the cheapness of the process, it brings a lower price.

2. *Steel of cementation.* The process of forming steel by cementation is performed in two parallel troughs constructed of fire brick, or of an open-grained siliceous free stone, unalterable by the fire. These troughs are placed upon a long grate beneath an arched vault, surrounded with a cone of masonry. Bars of the best Dannemora or oregrund (Swedish) iron, free of cracks and flaws, are then selected for the purpose of cementation. A layer of coarsely bruised charcoal, capable of passing through a quarter inch riddle, is now laid at the bottom of the cementing troughs, and above this is laid a row of bars of iron, another stratum of charcoal succeeds, and then bars of iron, and so on till the trough is nearly full, containing about eight tons of iron. The whole is then covered with clay and sand mixed, and rammed as close as possible to exclude the air. The heat of the whole is raised to a glowing red, which is kept up from seven to eleven days, according to the quantity of iron. Through a small hole in each trough a bar is allowed to project, that it may be taken out from time to time to observe the progress of the operation. When the trial bars announce the perfection of the process, the fire is extinguished. The bars retain their original shape, but their surface is covered with blisters, as if a gaseous fluid had been confined in different parts of it. Hence it is called *Blistered Steel.* The bar iron when thus converted into steel is found to have increased in weight from four to twelve oz. per cwt. or on an average 1 part in 224. The first proportion constitutes *mild*, and the second very hard steel; and if the process had been pushed much farther, the steel would have melted, and in the act of fusion would have taken an additional dose of charcoal, so as to bring it to the state of *Cast Iron*, No. 1.

Blistered steel thus made is used only for the coarsest purposes. Its texture is greatly improved by being formed into smaller bars under the tilt hammer, in which state it is known by the name of tilted steel.

In order to improve the steel still farther, the bars are broken into short pieces, and these being put up in small parcels, are welded together in a furnace, and drawn down into bars, which, by repeated welding and tilting, acquire a compactness and toughness, which fit it particularly for swords and other large articles of cutlery. This steel is called *shear steel*, or *German* steel, from its having been prepared in great perfection in Germany.

3. *Cast steel.* The finest kind of steel known by the name of cast steel was first made by Mr. Huntsman of Sheffield in 1750. At first he kept his process a secret, but it is now well known and universally practised. Blistered steel, broken into small pieces, is mixed with a certain proportion of pounded glass and powdered charcoal. It is then melted in a crucible, and cast into ingots, which, by gentle heating, under the influence of the tilt hammer, are wrought into bars. By this process it becomes more brittle and fusible than blistered steel; but though it is incapable of being welded with either iron or steel, it has acquired an uniformity of texture, and a closeness of grain, which fit it for the finest articles of cutlery.

According to M. Clouet (*Journal des Mines*, No. 49, An. vii. 3), cast steel may be formed by fusing thirty parts of iron, one of charcoal, and one of pounded glass, or even by melting iron in a crucible, when surrounded with equal parts of chalk and clay, and keeping the whole a sufficient time at a white heat. There is reason to think that the pounded glass is not essential to cast steel; and while some are of opinion that this substance differs from common steel only in having a greater quantity of carbon, others maintain that it actually contains less carbon, and therefore that the difference must have another origin. In rich cast iron the carbon is supposed by some to exist in a mechanical state, while in steel it is chemically united with the iron.

Various methods of working cast steel have been published, among which that of Mr. Mushet deserves to be studied. A method of a novel character has been recently discovered by our ingenious countryman, Charles Mackintosh, Esq. Glasgow. The principle of the method is to impregnate iron at a high temperature with carbon in a gaseous form. The gas which he employs as the most economical and convenient for this purpose is that obtained from the distillation of coal, or the common coal gas. The iron to be converted into steel is enclosed in a crucible, or melting-pot, of the usual materials, and placed in the furnace; and when it is raised to a very high degree of temperature, a jet or current of the gas is thrown into the crucible through a tube and aperture provided for that purpose. In the cover of the crucible another aperture is made to permit the escape of that part of the gas which is not absorbed by the iron.*

A series of very valuable papers on iron and steel

* See *Edinburgh Journal of Science*, vol. vii. p. 361.

by Mr. Mushet has been published in Dr. Tilloch's Philosophical Magazine. He has shown that the hardness of iron increases with the carbon which it contains, till the carbon amounts to one-sixtieth of the iron. At this point the hardness is a maximum, the metal acquires the lustre and colour of silver, loses its granulated appearance, and assumes a crystallized form. If more than one-sixtieth of carbon be added, the hardness of the compound diminishes in proportion to its quantity.

The following table by Mr. Mushet shows the proportions of carbon which combine with iron during the formation of the different carburets.

Soft cast steel, ...	$\frac{1}{120}$
Common cast steel, ...	$\frac{1}{100}$
The same steel, but harder, . .	$\frac{1}{90}$
The same, too hard for drawing, .	$\frac{1}{50}$
White cast iron, ...	$\frac{1}{25}$
Mottled cast iron, ...	$\frac{1}{20}$
Black cast iron, ...	$\frac{1}{15}$

The following are the specific gravities of steel in different states.

	Spec. Grav.
Best blistered steel, before hammering,	7.31
Do. do. after hammering	7.73
Very hard steel, ...	7.26
Melted steel wire, ...	7.5
English cast steel, hammered, .	7.82 to 7.91

On the Case-hardening of Iron.

The process of case-hardening iron is that by which the surface of articles already manufactured are converted into steel. It is chiefly used for table-knives, and particular surgical instruments, where toughness and hardness are required. The articles which are to undergo this process are laid into a pan of plate iron, and surrounded with bone shavings, pieces of horn, or old leather shoes. A forge fire of considerable size is now made up, and when the upper part of the fire has caked together, it is carefully lifted off without breaking, and the iron pan when laid upon the red coals, is covered with the caked mass. In this state it remains for two hours, without urging the fire. The progress of the operation is ascertained by small pieces of trial wire previously introduced into the pan, which are taken out, and dipped in water, then by means of the file and the character of the fracture, the condition of the articles is known. When the process is deemed complete, the fire is increased, and the articles, when brought to a proper heat, are taken out and immersed in cold water.*

On the Tempering of Steel, and the colours which accompany it.

The art of tempering steel and fitting it for various kinds of cutting instruments and other purposes, is one of the most important in the arts. The heat by which this change in its character is affected, must always be less than that which was used in hardening it. The common method of tempering consists in laying the steel articles on a clean coal fire, or on a heated bar till they receive the degree of heat which is required. They are then cooled by immersion in water. The degree of heat, the colour by which it is indicated, and the degrees of temper necessary for different instruments are shown in the following table:—

Instruments.	Colours.	Temperature Fahr.
1. Razors and instruments with a stout back and fine edge	Straw Colour	430° to 450°
2. Scalpels and Penknives	Full Yellow	— 470°
3. Scissors, small shears	Brown Yellow	— 490°
4. Pocket and Pruning Knives	First Tinge of Purple	— 510°
5. Watch Springs, Swords, and Elastic Instruments	Different Purples	550° to 560°
6. ————————		— 600°

As many articles of cutlery require to be tempered with great precision, Mr. Hartley, in the year 1789, took out a patent for a new method. This method consists in using an iron trough filled with the fusible metal, consisting of eight parts of lead, two of tin, and five of bismuth. A mercurial thermometer graduated to 600° of Fahrenheit is then immersed in it, and the fusible metal is brought to the required temperature by means of a furnace or lamp placed below the trough. In place of the fusible metal oil may be used, but as the articles are in this case immersed in the oil and out of contact with the atmosphere, the colours arising from oxidation are not produced. Mercury may be used in place of the fusible metal. No change of colour will appear on the steel till the thermometer indicates 430°, and it is so faint that it can be even then only seen by comparing it with a plate not heated. A very ingenious method of tempering very delicate steel articles was proposed by Dr. Wollaston to Mr. Stodart. The steel articles when placed in a tube were surrounded with the fusible metal. The tube with its enclosures was then heated to redness in a furnace, and afterwards immersed in a cooling fluid. The whole is then thrown into boiling water, which melts the fusible metal and leaves the steel perfectly hardened and unaltered by twisting, cracking, or suffering any change of form.

Mr. Stodart made several experiments in order to determine the best fluid for cooling the heated steel. He plunged a scalpel in a mixture of snow and muriate of lime, but without perceiving that any advantage was derived from the extreme cold. A large quantity of water brought to the temperature of about 40° of Fahrenheit he found to answer the purpose as well as any that had been tried. In tempering steel and the alloys of steel, to be afterwards described, Mr. Stodart recommends it to be performed twice, first at the usual time before grinding, and again just before the last polish is given to the blade. "This second tempering," says he, "will perhaps appear superfluous, but upon trial its utility will be readily admitted; we were led to adopt the practice by analogy, when considering the process of making and tempering watch springs."†

The following table, which is different from the one given above, is drawn up from a series of fine specimens of oxidated steel, which the late eminent Mr. Stodart presented to the writer of this article. The

* See Aikin's *Dictionary of Chemistry, &c.* vol. i. p. 602.

† *Philosophical Transactions*, 1822, p. 270.

different tints are twelve in number, and exhibit very perceptibly the progress of the oxidation :—

1.	Very pale straw yellow - -	430°
2.	A shade of darker yellow - -	450
3.	Darker straw yellow - - -	470
4.	Still darker straw yellow - -	490
5.	A browner yellow - - -	500
6.	Yellow, tinged slightly with purple	520
7.	Light purple - - - - -	530
8.	Dark purple - - - - -	550
9.	Deep blue - - - - - -	570
10.	Paler blue - - - - -	590
11.	Still paler blue - - - -	610
12.	Still paler blue, with a tinge of green	630

In the production of these colours the access of oxygen is absolutely necessary, in order that it may combine chemically with the metal. Sign. Ambrosio Fusinieri, who has made a number of curious experiments on the subject in reference to the other metals, found that these colours are produced in the same order on all metals except platinum, upon which, whether in the state of wire or plate, he never could produce any colour.*

Observations on the Hardening of Steel, addressed to the Franklin Institute, by Rufus Tyler, Mechanician, Philadelphia.

The following remarks on the subject of hardening steel, are offered to the Institute as the result of much experience in the regular course of my business, and of essays suggested by some peculiarity, accidentally noticed, and made for my own satisfaction. It is, perhaps, to be regretted, that I have not had leisure to repeat them with a view to greater accuracy of detail; by some, however, this may be deemed a favourable circumstance, as they are not fortified by any array of numbers, or formulæ, and may, therefore, be the more readily discussed, corrected, and amended, for which I am fully aware my best endeavours leave ample room.

The peculiar kind of hardening of which steel is susceptible, depends upon two conditions: first, *a sufficient degree of heat* (somewhat above the lowest red), which may be termed the hardening heat; and second, *sudden cooling*. A deficiency of only a few degrees of heat, or an excess of two or three seconds of time, beyond certain limits, will *entirely* defeat the operation.

The usual method of hardening steel for common purposes is to heat it to the proper degree (the lower the better, provided it be not so low as entirely to fail to harden), and then to plunge it suddenly into cold water. When it is requisite to protect the surface from the corroding effects of the atmospheric air, as in engravings, dies of delicate workmanship, &c. it should be imbedded in fine charcoal powder, previously heated to redness, in an iron box, to drive off the evaporable matter, and when sufficiently heated, the piece must be removed to the cooling liquid with as little exposure to the air as possible. If the contents of the box be thrown, with the steel, into oil, so as completely to exclude the air, it will preserve its polish and brightness unchanged.

All articles of steel are more or less liable to become warped, by rapid cooling, from the unequal contraction of the parts, and many, from the same cause, require the greatest dexterity and skill to prevent them from breaking in pieces during the operation.

Whenever, therefore, the nature of the case admits the use of oil, as a cooling medium, it is safer than water, being much less rapid in its operation. It is obvious, however, that as large masses of steel can with difficulty be cooled, even in water, within the hardening limit of time, only small articles, such as springs, thin blades, &c. can be hardened at all in oil. It is sometimes pretended that oil imparts a degree of toughness to steel hardened in it, just as it would to a bit of horn, or leather, by penetrating its pores; and I believe the patent obtained for the use of it, in hardening a *celebrated patent oil-hardened-spring truss*, was grounded upon such a supposition.

The danger of breaking increases with the *thickness* of the piece, whatever may be its form; and that form is least liable to break, in which there is the greatest freedom of motion, or in which a simultaneous contraction can be effected in all the parts.

In hardening a roller, say two or three inches in diameter, and about the same in length, the first tendency of the contraction of the surface is to separate it. But this strain being equally divided around the circumference, and the metal being in a yielding state, the only effect, in general, is to enlarge the surface beyond its original dimensions. The surface thus enlarged immediately becomes hard and fixed; so that the subsequent cooling of the centre reverses the strain upon the surface, tending to compress or shorten it, and that to such a degree, that a segment is often thrown off with great violence, or, when the outer portion has sufficient strength to resist the contracting force of the centre, that portion in its turn tends to separate, being prevented by the outer part (to which it adheres), from returning to its original dimensions. In this case, a separation at the centre is inevitable, unless a part of the heat be allowed to remain, until the surface be relaxed by tempering, after which it may be suffered to cool. When a rent commences at the centre, the parts generally separate with such force, as to sunder the mass, accompanied by a loud report.

It sometimes happens in the breaking of dies, rollers, &c. (in which the tempering has been omitted) that the effect does not take place until several hours, and even days, after they have been hardened.

Steel is allowed by authors to expand about $\frac{1}{8}$th of an inch to the foot, in heating to the hardening point, and to contract, on cooling, about $\frac{2}{3}$ds of what it had been expanded, provided the hardening effect takes place; otherwise it returns nearly to its original size. Accordingly, I have been in the habit of making allowances for this enlargement, which is generally found to take place, in a greater or less degree, and for many years held the opinion that it was a necessary consequence of hardening steel, and that this effect *ought* to take place, just in proportion to the degree of hardness produced.

With this doctrine, however, facts are at variance, and I believe, that the circumstance, above alluded

* *Giornale di Fisica*, vol. ii. p. 146.

to, as the cause of breaking, may also explain most satisfactorily, the phenomena in question, (to wit) that of hardening the exterior, before it can possibly be permitted to contract to its proper size, because of the expanded mass within.

I have found in a number of cases of thin hollow cylinders, or flattened rings, where there was the best chance of thorough, and almost instantaneous cooling, and of course, of producing the greatest degree of hardness, that no enlargement was perceptible.

Particular care should be observed, in the act of cooling, not to suffer any intermission, in any part, as is often done by moving the piece backward and forward, too briskly, in the water, alternately cooling, and exposing to a vacuum, the opposite sides; for a part thus exposed, after moving rapidly against the current, until fairly hardened, might be let down or tempered, as it is called, by the heat rushing from the centre, toward the side exposed to the vacuum, without being sufficiently re-heated to prepare it for hardening at the return of the current of the water. In this way, soft places are often produced, which will erroneously be attributed to uneven steel, want of sufficient heat, &c.

By dipping the end of a small bar (heated to several inches in length), and keeping it quite still, until it is hardened nearly to the surface of the water (which should be very cold); and then raising it quickly, an eighth of an inch, or more, according to the size of the bar, a portion of what was hardened will be softened by the heated part above;—as soon as this is perceived, let the bar be again sunk into the water, to where it remains of a hardening heat, which will be perhaps half of an inch lower than before, another portion of about $\frac{3}{8}$ths of an inch will thus be hardened; let the bar be again withdrawn a small distance, as before, repeating the operation, until there no longer remains sufficient heat in the bar for hardening; the result will be, a number of successive hard and soft rings.

While testing the strength of different kinds of steel, by repeatedly hardening each kind, until a fracture should take place, I was somewhat surprised to find the pieces, which were small (such for example, as were an inch square, and $\frac{3}{8}$, or $\frac{1}{2}$ an inch thick), considerably swollen, after three or four times hardening, and that every hardening increased their convexity, until they actually burst the surface, in the middle of one of the faces. Repeating the experiment, with a piece prepared perfectly flat, I found the first, second, third, and fourth time, of hardening each, to produce a small additional elevation of the surface. On the fourth attempt the piece cracked.

I have seen a thin piece of steel very beautifully hardened, by chilling in its passage through a rolling mill; this piece afterwards exhibited in its fracture an exceedingly fine grain, a probable consequence of its being hardened under immense pressure.

Small drills, and other articles of the thickness of a small needle, may be cooled, with sufficient rapidity to become hard, by moving them briskly through the air.

Water, to be active, in cooling, should be perfectly free from soap,—a small portion of that substance will cause the time of cooling to be extended beyond the hardening limit, especially if the piece of steel be not very small.

The grain of steel, though finer when hard than when soft, becomes still finer, the lower the temper be drawn, until about a medium between hard and soft, when the fineness begins to decrease.

Cast iron is capable of being hardened in the same manner as steel, except the kind which is already hardened at the time of casting. This kind possesses a superior degree of hardness, which differs materially from that obtained in the manner of hardening steel. It takes place in passing from the fluid to the solid state, and can only be changed by re-melting. As soon as time will permit, I intend offering some remarks on hard and soft cast-iron.

The most satisfactory theory of hardening steel, which also applies to cast iron, is one suggested by Mr. William Mason, of this place. He supposes, that at the hardening heat, the component parts of steel exist in a state of perfect chemical union, and that if time be allowed in cooling, that union is dissolved, or changed to a simple mechanical mixture. This he conceives to be supported by the following experiment: melt together certain proportions of zinc and quicksilver, and pour one part of the amalgam into water, and the other into a wooden or paper mould; that which is poured into water being suddenly chilled, retains its chemical union, and becomes of the consistence of paste; the other separates, the zinc forming a solid cellular body, holding the quicksilver in very minute globules, in its interstices.

On Annealing Cast Steel, so as to make it as soft as Iron.—By Jacob Perkins.

We were lately shown by an American friend, some slips of thin cast-steel, which were as soft and pliant, and as easily bent into any required shape, as though they had been tinned sheet-iron. They were of a light grey colour, perfectly free from oxidation or scales, and were still capable of hardening, on being heated and quenched in water.

On mentioning this fact to Mr. Perkins, he stated that the process was known to him, he having practised it in America with great advantage; and he had even communicated it to one intelligent engineer in this country, who had since constantly employed it.

The secret consists in inclosing the cast-steel in close cast-iron vessels, which completely exclude the external air; and in keeping them at a moderate red heat, in a proper annealing furnace, a sufficient length of time, according to the thickness of the steel; and, lastly, letting them cool very slowly.

This process is superior to the usual practice of decarbonating cast steel, and reducing it to the state of iron; which renders it necessary to restore its steely nature again, by case-hardening it, before it can be hardened as usual. [*Tech. Rep.*

On Annealing Iron and Steel Wire.—By Thomas Gill.

Although "the annealing of cast-steel in close vessels," as described to us by Mr. Perkins, and as given in the preceding article, was a new and valuable fact; yet we well knew that a similar practice had long been used both in this country, and in France, for annealing iron, and steel wire.

The late scientific M. Nicolas Paul, of Geneva, described to us, twenty years since, the practice employed in an iron wire drawing manufactory in France, to anneal their wire; which was by enclosing the large coils, in cast-iron vessels of an annular or ring shape, open in the middle, to allow the flame of the furnace to play through them; and the section of which rings was a semi-circle, having flat cast-iron rings, as covers to the flat tops of the vessels. Ears were made around the internal, and external boilers, both of the vessels and their covers, with corresponding holes in them, into which wrought-iron pins, with heads, were put, and which pins had also holes near their ends, through which iron wedges were driven, to draw the covers close to the vessels, the juncture being previously made air-tight by a luting of loam. These vessels were heated in a kind of oven-shaped furnace, having a grate of iron bars, for the fuel, and vessels, to rest upon, with doors both to the oven and ash-pit.

We also saw, about the same time, the method employed by the late Mr. John Burr, at his steel wire works, near Hales-Owen, in Shropshire. He enclosed his bundles or coils of steel wire, for needle and fish-hook making, in cast-iron vessels, with covers fitted closely to them, to exclude the air. These vessels were uniformly heated in a cylindrical furnace of brick-work, covered with a dome, and having a hole in the centre of the dome, to serve as a chimney. The furnace was strengthened by a number of projecting buttresses, which were built around it, and by iron chains surrounding the brick-work. The fire was made upon a circular grate, which ran all round the inside of the furnace, and was supported upon walls; air-holes to supply the fire being also made at regular distances through the external wall of the furnace. A door of brick-work was built up, after the coal fire had been lighted, and the vessels containing the steel-wire, had been deposited in the furnace; this of course was taken down again after the annealing was performed, and the furnace had become sufficiently cool to remove the vessels.

In Cadell's "Journey to Carniola, Italy, and France, in the years 1817 and 1818," he says, vol. i. page 243, that in the iron wire works, near to Pistoja, in Italy, "after the wire has been drawn, it is hard; and, in order to restore its flexibility, it must be heated, and suffered to cool, gradually. For this process of annealing, large cast-iron vessels are employed, four feet high, in form of a truncated cone with the base uppermost. The wire is put into the vessels, which are then covered and luted tight. The vessel is surrounded by a brick-wall, at some distance from its sides, and burning charcoal is put in, between the vessel, and the wall. These cast-iron vessels are made at the furnaces in the Maremma, and they are almost the only articles of cast-iron I observed in Tuscany."

In our first volume, page 423, we mentioned, that Mr. Corcoran, of Mark-lane, wire weaver, inclosed his wire in closed cast-iron vessels, *surrounded with ground flint*, and then exposed them to a red-heat, in proper furnaces. And that, although the wire thus became quite flexible and pliant, yet it was as bright as though it had not been heated at all. [*Ib.*

Remarks by the Editor of the Franklin Journal.—We had been so long familiar with the foregoing process, that we had supposed it to be the universal practice in wire manufactories. The Messrs. Sellers of this city have used it for many years; it was also followed by Messrs. White & Hazard, at their wire drawing manufactory, at the falls of Schuylkill, and by many other persons in this country; but as it may be new and useful to some persons who work in wire, we have re-published it.

On a new method of Colouring or Ornamenting Steel. By M. Leopold Nobili, of Reggio, in Italy.

In the *Bulletin de la Société d'Encouragement*, for January 1829, is contained a report made by M. Gualthier de Claubry, a member of that society, as follows:

"A learned foreigner, known by his ingenious researches, M. Leopold Nobili, having presented to this society the results of his experiments relative to a new art, to which he has given the name of *métallochromie;* you charged your committee of the chemical arts to examine these products; and I have, in its name, to report thereon.

"A great number of experiments, more or less successful, have been made by various persons, and at different periods, to apply, in a solid manner, paintings upon metals; but the solidity of the pictures did not equal their wishes, and the thinness of the colours applied rendered their traces vague, and greatly diminished the sharpness and finish of the designs.

"M. Nobili has lately, by his assiduous researches, and the labour of many years, produced, by a process which he has not made known, designs upon various metals, in which the brilliancy of the colours, and the harmony of the tints, leave nothing to be desired; thus these colours possess none of the inconveniences above stated; and they are developed upon the surface of the metals without being too thinly diffused; but are stable, and will not disappear unless by the application of a high red heat, which, by its action, would also destroy the surface of the metal, as well as the chemical agents employed upon it.

"Nothing can be more brilliant and singular than the colours upon M. Nobili's plates, especially by day light: and all his designs are executed with a fine taste, the regularity of their forms, and the sharpness of their outlines, being all that can be wished.

"M. Nobili has not merely manufactured these plates as objects of curiosity, but has mounted several, which have been singularly esteemed by amateurs; and we can readily believe that this pleasing art would meet with great success were it carried into effect on a proper scale: and it is, therefore, much to be desired that so new and curious an art should not be lost to France, and especially as M. Nobili appears disposed to bring it into practice. We can easily form a just idea of the extent to which it might be possible to carry this branch of manufacture, when we remark that many metals assume their colours in very different orders by the application of heat; and we can easily conceive, that in the hands of a skilful man, and one well conversant with commerce, the greatest advantages might be derived from the employment of this new branch of industry. Thus, for instance, nothing presents more harmony than gold, as its tints are very different from those afforded by heating steel. It is upon this last metal that all the designs presented by M. Nobili have been executed. Silver likewise affords different colours on applying heat; and an experienced artist cannot fail to make many fine applications of M. Nobili's process.

"This process not being exactly known, many persons have accordingly formed suppositions, and even made experiments respecting it; but it does not appear that their suppositions have been well founded; and their success has been much less happy, and their colours less perfectly developed upon the surface of the metal, than can be effected by an art which has acquired perfection in the hands of M. Nobili.

"Under the impossibility, then, of being able to speak positively as to the manner in which M. Nobili has been able to produce these curious effects, we can only applaud the incessant efforts which he must have made to bring his art into the perfect state in which we find it. All those, who have attempted new branches of manufactures, may well conceive the difficulties which every day presents, and which can only be overcome by a continued zeal and efforts to surmount unsuccessful endeavours; and M. Nobili could not otherwise have arrived at the point of perfection to which he has brought his *métallochromie*, nor can he be too much praised for the success he has obtained.

"We again repeat, that it is much to be desired that so curious an art should not be lost to France; and the committee of chemical arts, in order to forward this object, have charged me to propose, that M. Nobili be recompensed for his interesting communication, by inserting this report in the *Bulletin* of the society."

The following Letter on ornamenting Steel with Gold and Platina was addressed to the Editor of the Technical Repository.

Bridge Cottage, Camberwell, Jan. 8th, 1826.

Sir,—In a paper inserted in your Repository for November last, I suggested some inquiries respecting the various methods of gilding practised by artizans. Since that period, I have been prosecuting some experiments with success, for ascertaining the proper mode of superficial gilding upon steel: and I transmit the result to you, for the benefit of that class of artists. It is necessary, perhaps, to premise, that the instructions given, in most elementary works upon chemistry, for gilding with the ethereal solution of gold, are either erroneous, or not sufficiently explicit; and to this cause may be traced the many failures which have occurred in practising this art.

The following is the process which I used; and which answers equally well, either for gold or platina.

Dissolve any quantity of gold or platina in nitro-muriatic acid (*aqua regia*), until no further effervescence is occasioned by the application of heat. Evaporate the solution of gold or platina, thus formed, to dryness, in a gentle heat (it will then be freed from all excess of acid, which is essential): and re-dissolve the dry mass in as little water as possible: next take an instrument which is used by chemists for dropping liquids, known by the name of a separating-funnel, having a pear-shaped body, tapering to a fine point, and a neck capable of being stopped with the finger or a cork; which may contain a liquid ounce, or more: fill it with the liquid about one quarter part; and the other three parts must be filled with the very best sulphuric ether. If this be rightly managed, the two liquids will not mix. Then place the tube in a horizontal position, and gently turn it round with the finger and thumb. The ether will very soon be impregnated with the platina or gold, which may be known by its change of colour. Replace it in a perpendicular position; and let it rest for twenty-four hours; having first stopped the upper orifice with a small cork. The liquid will then be divided into two parts; the darkest coloured being underneath. To separate them, take out the cork, and let the dark liquid flow out: when it has disappeared, stop the tube immediately with the cork; and what remains in the tube is fit for use, and may be called the gilding-liquid. Let it be put into a bottle, and tightly corked. When an article is to be gilded, a vessel of glass or unglazed ware must be provided, of just sufficient size to admit the article: it must then be filled with the gilding-liquid, nearly to the top. The steel must be *very highly polished*, and be entirely free from *rust* or *grease*. A basin, full of clean water, must be ready at hand: the article must be immersed into the gilding-liquid, and allowed to remain *as short a time as possible*; then be taken out, quickly plunged into water, and well rinsed: it must next be dried with blotting-paper, and be placed in a temperature of 150° Fahr. till it be completely heated throughout: it may then be polished with rouge and a soft leather; or, which is better, be burnished.

It will be as well to observe, perhaps, that the muriate of gold or platina, formed by digesting these metals in nitro-muriatic acid, must be entirely free from all excess of acid; because it will otherwise act too forcibly on the steel, and cause the coating of gold to peel off. Pure gold must be employed. The ether must not be shaken with the muriate of gold, as is advised in chemical publications, for it will be sure, then, to contain acid: but, if the two liquids be continually brought into contact, by the motion I have described, the affinity between ether and gold is so strong, as to overcome the obstacle of gravity, and it will hold the gold in solution. The etherial solution may also be concentrated by gentle evaporation. Care must be taken not to wipe the steel until the heat has been applied. This gilding is an effectual protection against rust: and is, at the same time, very ornamental.

Thomas Gill. Nicholas Mill.

Damascus Steel.

The steel of which the beautiful sword blades of Damascus are manufactured, has hitherto baffled all attempts at imitation. It is generally supposed to be made of slips or thin rods or wires of iron and steel, bound together by iron wire, and then melted together by heat. The most skilful workmen of other countries have attempted to imitate this process, but in vain: so that there is reason to think that the secret of the manufacture has not yet transpired. The colour of the Damascus blades is a dull bluish grey, and scarcely exceeds in hardness common steel from the forge. It is difficult to bend; and when bent does not resume its shape: the principal character, however, is its *water*, or a peculiar wavy appearance running from the hilt to the point in narrow lines, the thickness of a harpsicord wire, which never cross each other. These waving lines arise from a slight difference in the degree of polish occasioned by the unequal action of acid upon the steel; any weak acid would produce this effect, but at Damascus sulphate of alumine is acid. This appearance of waving lines has been imitated by a false damasking or etching, but the genuine Damascus blade is distinguished from the false one by the obliteration of the lines in grinding, which takes place in the latter. In the real Damascus blades, grinding nearly removes the water; but it immediately reappears by rubbing the blade with lemon juice.

On Indian Steel or Wootz.

This valuable material has lately been introduced with great success into cutlery. Sir Joseph Banks was the first person who drew the attention of the public to Wootz, having received it from Dr. Scott of Bombay, and submitted some of it to the trials of skilful workmen so early as 1795. It is imported in the state of round flat cakes, about five inches in diameter, and an inch thick, each weighing more than two pounds. The following is the method of making it in India. Pieces of forged iron and wood are enclosed in a crucible, and heated together in a furnace. The fire is urged by three or more pair of bellows peculiar to the country. In this way the wood is charred, and the iron is melted and converted into steel. It crystallizes in the crucible in the state above mentioned. According to Mr. Stodart it ought to undergo a second fusion, which should be conducted with the greatest care, and when this is well done, it is so much improved as to be fit for every purpose of fine cutlery, and infinitely superior to the best cast steel of England. In forging, it requires the utmost attention. Dr. Scott informed Sir Joseph Banks, that it "cannot bear anything beyond a slight red heat;" for when this happens, part of the mass seems to run, and the whole is lost as if it consisted of metals of different degrees of fusibility. Mr. Stodart also found that it was useless when overheated, that in hardening it should be quenched at a cherry-red colour, and while tempering, it should be heated from thirty to forty degrees higher than the best English cast steel.

According to Dr. Pearson's * analysis, it seems to differ from steel only in containing a little oxide of iron. He and Mr. Moore obtained the following measures of its specific gravity.

1. Wootz - - - - - -	7.181
2. Ditto another specimen - -	7.403
3. Ditto forged - - - - -	7.647
4. Another specimen forged -	7.503
5. Wootz which had been melted -	7.200
6. Wootz quenched while quite hot	7.166

The following measure of the specific gravity of wootz in different states was obtained by Messrs. Stodart and Faraday. The results are remarkable for being so much higher than the above:

Wootz unhammered from Bombay -	7.665
Wootz tilted from Bombay - -	7.6707
Wootz in cake from Bengal - -	7.730
Wootz fused and hammered from Bengal	7.787

* *Phil. Trans*: 1775, p. 322.

Wootz has been more recently (1819) examined by Mr. Faraday.† The piece which he used was cut from the middle of the cake given by Sir Joseph Banks to Mr. Stodart, when heated cherry-red. In 460 grains he found besides the carbon and iron, 0.3 of a grain of silex, and 0.6 of a grain of alumine. The best English cast steel, submitted to the same experiments, yielded no earths. Mr. Faraday attempted in vain to imitate wootz, although he obtained specimens of iron giving abundance of silex and alumine by analysis.

On a future occasion, however, he was more successful by employing the following method. Pure steel in small pieces, and in some cases good iron when mixed with charcoal powder were heated intensely for a long time. In this way were formed carburets highly crystalline, and of a dark metallic grey colour, like the black ore of tellurium. When broken the facets of several buttons of 500 grains were about the eighth of an inch wide. This carburet consisted of

Iron - - -	94.36
Carbon - -	5.64
	100.00

This metal when reduced to powder in a mortar was mixed with pure alumine, and the whole subjected to an intense and long heat. An alumine alloy was thus obtained of a white colour, a close granular texture, and very brittle. It contained 6.4 of alumine. With 67 parts of this alloy 500 grains of good steel were fused, and formed a perfectly malleable button which forged well, and gave the beautiful damask peculiar to wootz, by the application of dilute sulphuric acid.

This specimen had all the appreciable characters of the best Bombay Wootz. Hence Messrs. Stodart and Faraday were of opinion that wootz is steel accidentally combined with the metal of the earths, the earth being either in the ore, or derived from the crucible in which the prism is made. It will appear, say these chemists, from the following experiment, that we had formed artificial wootz when it was not the object of research. In an attempt to reduce titanium, and combine it with steel, a portion of menachanite was heated with charcoal; a part of the button thus obtained was next fused with some good steel in the proportion of

Steel - - - - -	96
Menachanite button -	4
	100

The alloy thus obtained worked well under the hammer, and the bar obtained was evidently superior to steel. This was ascribed to the presence of titanium, but no titanium could be found in it, not even in the menachanite button itself. *The product was iron and carbon, combined with the earths or their bases, and was in fact excellent wootz.* On this specimen a beautiful damask was produced by the action of dilute acid.

On the Alloys of Steel.

The curious observation of Sir Humphry Davy, that mercury is rendered solid, and experiences a diminution of specific gravity from 13 to 3 by combining with $\frac{1}{12000}$dth part of ammonium, seems to have impressed on Mr. Stodart's mind the important fact that a very minute quantity of one metal is capable of producing extraordinary effects by combining with another.

Hence he was led, in conjunction with Mr. Faraday, to perform a series of interesting experiments on the alloys of steel with small quantities of gold, silver, platinum, rhodium, iridium, osmium, and palladium.* A brief account of the results is all that our limits will permit us to give.

1. *Alloy of Steel with Silver.* When *one* part of silver and *five hundred* of steel were properly fused, a button was produced which forged well, and formed various cutting tools decidedly superior to those made of the very best steel. The metals were in a state of perfect chemical combination, and by a delicate test the silver could be detected in every part of the alloy. When more than $\frac{1}{500}$dth part of silver was used, the excess was only mixed mechanically with the steel, and a silvery dew exuded from the metal when it contracted by cold or was hammered.

2. *Alloy of Steel and Platinum.* An alloy of 100 parts steel and 1 platinum † was forged into bars remarkable for smoothness of surface and beauty of fracture. Though less hard than the preceding alloy, it was considerably tougher. This alloy is powerfully acted upon by weak sulphuric acid, the action increasing with the quantity of platinum in the alloy.

Equal parts of steel and platinum produced a beautiful alloy, which takes a fine polish, and does not tarnish. It is peculiarly suitable for specula, and its specific gravity is 9.862.

3. *Alloy of Steel with Rhodium.* Alloys of steel with from one to two per cent. of rhodium, possess the valuable property of hardness, with tenacity sufficient to prevent cracking either in forging or hardening. This superior hardness is so remarkable, that in tempering for cutting articles, Messrs. Stodart and Faraday found, that they required it to be heated fully 30° Fahrenheit higher than the best wootz, wootz itself requiring to be heated fully 400 above the best English cast steel. The great scarcity of rhodium will, however, prevent this alloy from ever getting into general use.

4. *Alloy of Steel with Gold.* This alloy is good, though it does not promise to be so valuable as the preceding ones.

5. *Triple Alloy of Steel, Iridium, and Osmium.* This alloy is also one of great value.

6. *Alloy of Steel with Palladium* resembles the preceding.

7. *Alloy of Steel with Chromium.* This alloy was first made by M. Berthier,‡ who speaks very favourably of it. Messrs. Stodart and Faraday fused 1600 grains of steel with 10 of pure chrome. The button forged well, and though hard showed no disposition to crack. Another button, made of 1600 grains of steel and 48 of chrome was harder than the first, but was as malleable as pure iron.

Tin and copper were also alloyed with steel, but they did not seem to improve it.

The editor of this work has now before him highly polished specimens of four of these alloys, viz. those of platinum, gold, silver, and rhodium, which were presented to him by the late Mr. Stodart. They have now been kept for nearly *seven* years with different specimens of highly polished steel also given him by Mr. Stodart. The specimens of steel are all rusted, while there is not a spot upon any of the alloys. The much lamented death of Mr. Stodart has, we fear, delayed for a while the introduction of these valuable alloys into the arts; but we trust the subject will be again resumed by some skilful individual, who unites great practical skill with scientific knowledge.

STEEL, Engraving on. This highly important art has been recently revived and perfected by our countryman Mr. Warren, an engraver in London. Mr. Warren unfortunately died in the middle of his labours, but the art has been generally introduced into Great Britain by Messrs. Perkins and Fairman, two American gentlemen, who, along with Mr. Heath, an eminent London engraver, formed an establishment in 1819 for printing bank notes and engravings for popular works from steel plates.

The following history of Mr. Warren's experiments and discoveries was drawn up by a committee of the Society of Arts.

"Some of the earliest specimens of engraving upon steel were produced by Albert Durer. There are four plates etched by this artist, impressions of which exist in the British Museum, which in all books of art are recorded as having been executed on steel; of these one has the date 1510 inscribed upon it. Since that time attempts have been made occasionally to employ steel instead of copper as a material to engrave upon, but apparently with little success, on account principally of the great hardness of the material, which in a short time blunted and destroyed the tools which were made use of.

Steel exists in two states, the *elastic* and the *brittle*, the former being considerably softer than the latter: of the elastic steel a saw blade may be considered as an example, and in fact pieces of saw blade were the material upon which nearly all the first attempts have been made, of late years, to revive a practice which, if successful, offered so many advantages to the artist and to the public. Mr. Reimbach, a few years ago, executed an engraving on a block or thick plate of steel, but met with so many difficulties in the execution that his experiment remained insulated, and produced no sensible effect on the art of engraving.

Mr. Warren, in his early youth, was much employed in engraving on metal for the use of calico printers and gunsmiths, and the experience thus acquired induced him afterwards to turn his mind to the subject with a view of applying it to the fine arts. It was suggested to him by Mr. Gill, that the Birmingham artists, in the manufacture of articles of ornamented steel, subjected the steel, when rolled into sheets, to the process of decarbonization,

* *Philosophical Transactions*, 1822, p. 253—271.
† The platinum was produced by heating the ammonia muriate in a crucible to redness.
‡ *Annales de Chimie*, tom. xvii. p. 55.

by which it was converted to pure soft iron. It was then made into the required instrument, the ornamental work engraved or impressed upon it, and it was then by cementation with the proper materials, again converted superficially to steel, and thus rendered capable of acquiring the highest polish.

In the attempt, however, to apply this process to plates for the engraver's use, two opposite difficulties occurred. A plate of steel of the same thickness as that of common copper plate, when thoroughly decarbonized, and thus reduced to the state of very soft iron, yields readily to the graver and other tools, and, especially, is susceptible of the process of *knocking up;* this consists of scraping out the error, and afterwards striking the under side of the plate with a punch and hammer, in order to raise the cavity to the general level, and thus allow the artist to take the error out without occasioning any unevenness at the engraved surface: it was found, however, that plates of the thinnesss requisite for this operation, and of the usual dimensions, were very liable to warp in the last, or re-carbonizing process, and were thus rendered incapable of giving perfect impressions. If, in order to avoid this disadvantage, blocks, *i. e.* plates of three or four times the ordinary thinness, were made use of, the warping indeed was prevented, but at the same time the process of knocking up became impracticable and it was necessary, in order to remove an error or defective part, to grind out the surface, or to drill a hole from the under surface almost through the plate, and then, by forcing in a screw, to raise that part of the face which was immediately above it. This latter process, however, was so tedious and difficult, as exceedingly to detract from the advantage of substituting steel for copper.

In this state of things, it became a very interesting object of inquiry to ascertain how many impressions may be taken from a plate of soft or decarbonized steel: and it was found that such a plate, prepared according to Mr. Warren's process, is capable of affording several thousand copies without undergoing any visible wear. In proof of this, impressions were laid before the committee by Mr. Warren from the plates of decarbonized steel, executed by him, the one for an edition of Mackenzie's works, published by Cadell, the other for an edition of Beattie and Collins, published by Rivington. These exhibit, both in the landscape and in the figures, the most elaborate and delicate work: five thousand impressions have been taken from one, and four thousand from the other, and yet between one of the first and one of the last impressions, it was impossible to detect any perceptible difference.

If Mr. Warren had carried on his experiments alone, working by himself till he had brought his plan to perfection, it is probable that, at the period of his death, the evidence of the great importance of his discovery would by no means have been so complete as it actually was, and the result of his exertions might have been lost, to the great detriment of the profession, and of the fair fame of this eminent artist: but selfishness and secrecy in anything, which related to the improvement of the art to which he was attached, formed no part of his character; and all his discoveries, both those relating to the preparations of the plates as well as those which have reference to the engraving upon them, were unreservedly and gratuitously communicated. The consequence of this liberality was, that besides the plates of Mr. Warren's own engraving produced before the committee, impressions were shown of portraits engraved on decarbonized steel, for the Evangelical Magazine, demonstrating that after 25,000 copies have been taken, the plates still remain in a good state, and are not yet in want of repair. Mr. Mar stated, that having made an engraving on one of Mr. Warren's plates, he did not take his own proofs till after the 8000th impression; and, in another instance, the engraving being a portrait, Mr. La Hie, the printer, certified that the artist's own proofs were not taken off till after the 20,000th impression.

Mr. Warren's original process for decarbonizing the steel plates, consisted in procuring a box; or case of iron, and covering the bottom of it with a mixture of iron turnings and pounded oyster shells: on this a steel plate is laid, another bed of the mixture is then added, and so on alternately, till the box is full, taking care that the test of the compositions shall form the upper as well as the lower layer. The box so charged is thus to be placed in a furnace, and to be kept for several hours at the highest heat which it will bear without melting, after which, being allowed to cool gradually, the plates are found to be reduced, for the most part, to the state of soft decarbonized steel.

Mr. Hughes, a copper-plate maker, having been instructed by Mr. Warren in his process, and finding that the steel did not always turn out sufficiently and uniformly soft (particularly for the purpose of engravers in mezzotinto), imagined that these occasional defects were owing to a deficiency of heat in the cementing process; accordingly, he substituted a case or oven of refractory clay, for the cast iron one, and then applying a considerably higher heat than the cast iron box would have endured without melting, was enabled to obtain plates so soft that they may be bent over the knee. Each plate requires two or more cementations; and, as the first cementation warps them more or less, Mr. Warren was in the habit of rectifying them by means of a hammer. Mr. Hughes finds that the places struck by the hammer are apt to be less softened by the second cementation than the other parts, and therefore, that plates so treated will often turn out unequal in hardness. His own practice is to use a mallet, and as little force as possible, in detaching the cement from the surface, and in rectifying the plate.

The plate, being cleaned and polished (but not too highly), is ready for the engraver. When it comes into his hands, the first operation is to lay the etching ground, in doing which the plate must be rather less heated than is usual with copper, otherwise the ground, as it cools, contracts, presenting a honey-combed surface, and leaving parts of the plate uncovered. The same defect is apt to occur if the plate is too highly polished. The ground should be laid rather thicker than on copper.

Various menstruums were made trial of by Mr. Warren, for biting in with. Nitric acid, considerably more diluted than for copper, was made use of, with, upon the whole, good success. Nitrate of mercury was found to blunt or round the edges of the lines; acetic acid, with a small portion of nitrate of copper, produced the same effects: sulphate of copper bit light tints very beautifully, but its farther action rendered the lines rough. The best menstruum, however, is half an ounce of crystallized nitrate of copper, dissolved in a pint and a half of distilled water, and a few drops of nitric acid added to the solution. This will be found to bite both deeper and clearer than dilute nitric acid.

It will be advisable for the artist, when first etching on steel plate, to keep a register of the time which he finds necessary for the menstruums to act before the parts have attained their due degrees of strength, and this will serve as a guide to him in his subsequent operations. Mr. Warren generally found about two minutes sufficient for an outline, unless it was required to be very strong; the middle tint was produced in about ten minutes, and the darkest shadows in forty minutes. The menstruums should not be more than one-sixth of an inch deep on the plate, otherwise it will be difficult to see the work, and it becomes exhausted in about ten minutes, and thus requires to be replaced. While the menstruum is acting, the work must be constantly swept with a camel-hair brush, in order to remove the precipitated copper, which, if allowed to remain in the lines; renders their edges rugged, and destroys their beauty, especial care must be taken to clear the ends of the lines, as they are most liable to bite foul. In stopping out the ground (Brunswick blacks) must be laid on very thin and even, and, instead of terminating abruptly, must be re-washed off very gradually; for the smallest ridge or prominence will retain the copper, and then the ground will infallibly be penetrated, and the biting will become foul. By attending to these directions, an etching may be obtained on decarbonized steel, as deep and quite as sharp as it can be on copper. Concerning the great superiority of steel-plate over copper-plate, for all works that require a considerable number of impressions to be taken, there can exist no doubt; for though the use of the graver, and of the other tools, requires more time on steel than on copper, and though the process of re-biting has not yet been carried to the degree of perfection in the former that it has been in the latter, yet the texture of steel is such as to admit of more delicate work than copper; and the finest and most elaborate exertions of the art, which on copper would soon wear so as to reduce them to an indistinct smeary tint, appear to undergo scarcely any deterioration on steel; even the marks of the burnisher are still distinguishable after several thousand impressions.

The improvements on the art of engraving upon steel made by Messrs. Perkins, Fairman, and Heath, are of such a nature as to give them almost the character of the first inventors of the art. The following is their process of multiplying engravings, etchings, or engine work. The steel blocks or plates which are to receive the intended engraving, have their surfaces softened or decarbonized, and thus rendered more suitable for receiving all kinds of work than on copper. When the engraving upon the block has been executed, the plate is completely hardened by a new process which does not injure in the slightest degree the most delicate work. A cylinder of steel previously softened is then placed in the transferring press, and repeatedly passed over the engraved block, by which the engraving is transferred *in relief* to the circumference of the cylinder; the press having a vibrating motion equalling that of the cylinder upon its circumference, by which new surfaces of the cylinder are presented equal to the extent of the engraving. This cylinder is then hardened, and is employed to indent copper or steel plates with engravings identically the same as the one on the original steel block, and this may be repeated *ad infinitum*, as the original engraving will remain, from which other cylinders may be impressed if required. When the engraving is of too great a size to be transferred, it is executed upon a steel block, from which when hardened, 200,000 perfect impressions may be taken.

In our pottery manufactures, in calico-printing, but particularly in preventing the forgery of bank notes, &c., this art will be found of the greatest importance.

We have already seen that Mr. Warren experienced difficulties in obtaining a good menstruum for biting in upon steel. Mr. Wilson Lowry discovered a menstruum, the composition of which he sold to Mr. Heath, by which the lines could be bitten in deep as well as broad, and the requisite fineness preserved. It is well known that some menstrua succeed well on hard steel, and yet give unsatisfactory results on soft and decarbonized steel. Nitric acid, which is the active ingredient in all these menstrua, usually reduces part of the iron to the state of that oxide which is soluble in the acid, and also converts a smaller portion to the state of peroxide which remains for the most part undissolved, adhering to the surface of the iron, and preventing that clean, deep, and uniform biting which it is the great object of the artist to obtain. The presence of carbon in a finely divided state has a tendency to interfere with the peroxidation of the iron, and this probably is the reason why it is less difficult to obtain a good effect with hard than with soft steel.*

Hence it became of consequence to have a menstruum by which these effects would not be produced, and this seems to have been obtained by Mr. Humphreys, who was rewarded by the society of arts for the discovery of the following menstruum.

Dissolve together in half a pint of hot water a quarter of an ounce of corrosive sublimate, and a quarter of an ounce of powdered alum. It is ready for use when cold. "While using it keep it stirring with a camel's hair brush, and take care to wash the plate perfectly after each boiling. As this acid, though clear before use, becomes turbid during its action on the steel, it may be prudent in fine works to throw away each portion of acid after it has been on the plate. The taste and experience of the artist must dictate the length of time he may leave it on his plate; delicate tints are obtained in about three minutes." For farther information on this subject, see *The Transactions of the Society of Arts for* 1823, vol. xli. p. 83; and Newton's *Journal of the Arts*, vol. xiii. p. 42.

On an improved mode of etching Steel Plates. By Mr. W. Cooke, *Jun., Engraver.*

From the Transactions of the Society for the encouragement of Arts, Manufactures, and Commerce.

Dec. 21, 1825.

Sir—As the Society of Arts have given a portion of their attention to the subject of engraving on steel plates, and as many experiments have failed, I feel great pleasure in making the following communication public through the medium of the society.

For the best mode of biting-in hitherto published, we are indebted to the great perseverance of Mr. Turrell; but the difficulty and danger of using his menstruum on a soft ground, or when the varnish is not sufficiently dry, induced me to use the acids in different proportions, and to leave out the alcohol, as the composition was found to act on the ground, causing the whole surface of the plate to be corroded; this has frequently happened.

It is necessary to mention, that all plates for landscape engraving should be made of steel not completely decarbonized.

I beg to submit a few preparatory directions previous to etching.

The steel should be carefully cleansed (before laying the ground) with turpentine only, omitting the whiting which is used in preparing the surface of copper.

The ground should be laid with as little heat as possible, steel needing not so much as copper; too high a temperature decomposes the ground, and occasions it to produce small air bubbles, or to evaporate in a light smoke from the surface of the plate; should this take place, the ground must be re-laid. It is also highly necessary that in etching the point should penetrate the surface of the steel, and the breath not be suffered to condense on the etching, as it will cause the lines to rust, and will prevent the acid from biting well. The plate being ready for biting-in, the process is as follows: mix, by gentle shaking, six parts of acetic acid, and one part of nitric acid.

This mixture, being very rapid in its action, should be taken off the plate at half a minute, and the acid well washed out of the lines with water, drying the plate well, but without the assistance of heat. Stop out the light tints with Brunswick black varnish; and then, for the purpose of washing the oxyd out of the lines, pour on the plate a mixture of six parts of water, and one of nitrous acid, letting it remain two or three seconds; take this off, and immediately repeat the former mixture without washing the plate between, with water. This process should be repeated for each tint.

The biting-in of a steel plate should be accomplished, if possible, in one day: this observation holds good in regard to other methods of biting, as the lines will sometimes attract oxygen from the atmosphere during the night, which will prevent their biting with the same degree of clearness as the day before.

When the biting is completed, and the ground taken off, with a strong tooth-brush and turpentine, clean out the remaining oxyd from the lines, using the fingers for the light tints; then rub the surface of the plate, to remove the bur, with the finest emery paper previously well used on the back of a steel plate to take off its roughness; the more this paper is used the more valuable it becomes for taking out the marks of the scraper from dry point tints.

Re-biting is performed by dipping a clean rag in a very dilute nitric acid, and rubbing it over those parts intended to be re-bitten until the surface becomes dull; clean the plate out as before mentioned, and in laying the ground the dabber should be used but little, as it is likely to take up the ground again; re-bite with a few drops of nitrous acid in four ounces of water, sufficient to make the water taste sharply of the acid.

The whole process for biting, or re-biting, should be performed in a temperature of about sixty degrees, or higher, and certainly not much below that point.

As the time required to bite-in is the principal thing to be observed, all the light tints should be tried every minute after the first biting; but the deeper ones will require a longer time. A little practice will show these remarks (apparently trifling) to be important.

Biting on very soft steel plates may be accomplished by using the following mixture:—three ounces of warm water, four grains of tartaric acid, four drops of nitric or sulphuric acid, one drachm of corrosive sublimate.

I also submit to the society a new method of graduating skies and other tints.

Incline the plate, by tilting it with two wedges, and pour the re-biting acid into a glass funnel, with a stick inserted in the tube, and kept steady by a twisted copper wire loop; drop the acid on the dark part, and according to the colour of the tint the acid should be made to drop faster or slower, which is regulated by the raising and lowering the stick in the centre, and gives to the acid a tremulous motion, until it is floated over the whole sky; this obviates the old method of sweeping or feathering, which, from the quick action of the acid, occasions streaks to appear in the tints when the ground is taken off.

It is important that engravers should make use of the best acids, and perfectly free from adulteration. From the cheapness of sulphuric acid it is sometimes used with muriatic, to adulterate the nitric acid. The following tests will discover them:—dissolve a little nitrate of barytes in distilled water, and add it to a small quantity of the nitric acid in a phial or test tube; if a white precipitate is discovered at the bottom, sulphuric acid is present; and muriatic acid will form, with a solution of nitrate of silver, a white cloudy precipitate; should either of these effects take place, the acid is not fit for use.

The purest acids are those manufactured by Mr. Remnant, Smithfield-bars, who has made them some years for the use of engravers.

Since writing the foregoing account, I have discovered means of making the ground adhere to the surface of the steel, without using acid to dull the surface.

Dissolve, by gentle heat (in a Florence flask), some powdered copal in oil of spike lavender, and evaporate to a thick consistence; then to one ball of ground, add about one drachm of the copal solution, each having been made warm previous to mixing: lay the ground as before mentioned, avoiding too much heat; the ground may then be laid with the same facility as on copper. I am, sir, &c. &c.

W. Cooke, Jun.

A. Aikin, *Esq. Secretary, &c.*

The above processes were performed on tinted steel plates, in presence of the committee of polite arts, to their entire satisfaction, and that of several engravers, who were specially invited to witness them.

On a Menstruum for Etching Plates of Soft Steel. By Mr. W. Humphrys.

From the Transactions of the Society for the Encouragement of Arts, Manufactures and Commerce.

April, 19, 1826.

Sir,—I have a communication to make to the Society for the promotion of Arts, Manufactures, and Commerce, of a menstruum for biting-in steel plates. I have for some time back communicated it to various artists, to get their opinion of its merits, and have the testimony of Messrs. Turrell, W. Finden, &c., that it is the best, cheapest, simplest, and safest in its operation of any acid yet discovered; and those gentlemen will be happy at any time to meet a committee to explain its qualities. In addition, I have specimens of its performance, from several engravers, to lay before the Society. I am, sir, &c. &c.

Wm. Humphrys.

A. Aikin, *Esq. Secretary, &c.*

The composition of the menstruum is as follows:

Take a quarter of an ounce of corrosive sublimate powdered, and a quarter of an ounce of alum powdered, and dissolve them in a pint of hot water.

Directions.—Let it cool before use. While using it, keep it stirring with a camel's hair brush, and take care to wash the plate perfectly, after each biting. As this acid, though clear before use, becomes turbid during its action on the steel, it may be prudent, in fine works, to throw away each portion of acid after it has been on the plate. The taste and experience of the artist must dictate the length of time he may leave it on his plate; delicate tints are obtained in about three minutes.

It appears from the experience of those artists who have practised engraving on steel, that several of the menstrua employed in the process technically called biting-in, will succeed with hard steel, but give results by no means so satisfactory, when employed on very soft, or nearly decarbonized steel. Nitric acid is the essentially active ingredient in all these menstrua; and the chemist well knows that when this substance is brought into contact with iron, it usually brings part of it to the state of protoxid, which is soluble in the acid, and also reduces a smaller portion to the state of peroxid, which remains, for the most part, undissolved, adhering to the surface of the iron, and thus preventing that deep, clean, uniform biting which it is the great object of the artist to obtain. The presence of carbon, in a finely divided state, has a tendency to prevent, or at least to retard, the peroxidation of the iron, and this, probably, is the reason why it is less difficult to gain a good result with hard, than with soft, or decarbonized steel.

The composition employed by Mr. Humphrys contained no nitric acid; and, from the testimony before the committee of Mr. W. Finden, Mr. Warren, Mr. Romney, and others, who have tried it, and also from the result of the experiments made in presence of the committee, appears to be superior, for biting-in on soft steel, to any menstruum that has hitherto been used.

STEELE, Sir Richard, a celebrated author, was born at Dublin in 1671 or 1676. He received his education at the Charter House and at Oxford. His principal works are *The Christian Hero*, *The Funeral*, or *Grief a la Mode*, *The Tender Husband*, *The Tatler*, *The Guardian*, *The Conscious Lovers*. He sat twice in Parliament, and was knighted by Geo. I. in 1715. Broken in his fortune and his constitution, he quitted the world and died in Wales in 1727.

STEELYARD. See Mechanics, Vol. XII. p. 603.

STENOGRAPHY, or Short-Hand, from στενος *confined*, and γραφειν to *write*, is the art of writing in small compass, or employing characters, which, by a few strokes, express many words, and enable a proficient to follow a speaker, and note his discourse with accuracy. But short-hand writing is also of great importance in those private departments of life, where much is to be composed, and many writings to be put in due form. It is of no small utility to gentlemen of the bar, who are often pressed for time, as, by means of this art, they can commit their thoughts to writing with rapidity and precision.

It is highly valuable to the clergy, who have to address the people on the most interesting subjects; and where, on that account, every thought and word should be correct. When the sentiments and expressions are properly arranged in the mind, they are easily committed to short-hand writing; and, if the characters be distinctly formed, and of an adequate size, which they ought always to be, they can be caught, by a glance of the eye, in the course of delivery, and without seeming to read much, which is sometimes disagreeable to the audience, the discourse may be given, with all the correctness and elegance with which it was composed, and this can scarcely be done, if there be a total dependence on the memory.

The history of short-hand cannot be accurately ascertained; but it may be presumed, that when the art of writing became common, certain contractions and arbitrary tokens would be contrived for private use; and attempts would soon be made to employ marks and characters, for assisting to recollect such speeches and harangues as were supposed to be worthy of remembrance.

Hieroglyphics are a kind of short-hand writing, and certain signs and emblems, as memoranda and means of reckoning, were found to be in use among the people in South America, when they were first discovered. Stenography appears to have been early in use among the Greeks and Romans, and having found its way into Britain, it has made rapid progress within these 150 years, and has now arrived at great perfection. To acquire this useful art there is less difficulty than to become master of the Greek alphabet, and the common contractions of that language.

The difficulty which a learner finds to read what he has written is the most discouraging part of the process; and it is generally on this account that so many have abandoned the pursuit after they have begun it. But most assuredly, if the rules be attended to which are given in the following system, the whole will become easy and delightful. The chief embarrassment has arisen from writing short-hand, according to some systems, altogether without vowels; but although this may be done, and read by a proficient, yet the difficulty attending it is discouraging to a beginner.

The method recommended in this system, and which I have found in practice to be completely effectual, is to express the long vowels, but to omit those which have a short sound. This is in perfect analogy to the method of reading the Hebrew language without the points. The letters *aleph*, *he*, *yod*, *ain*, and *vau*, express the vowels *a*, *e*, *i*, *o*, *and u*, when they are sounded long; and wherever they are not in use, which sometimes happens in whole words of that language, these vocables are read without difficulty, for by adding the consonants together, a short or obscure vowel sound must be heard, and the word perfectly intelligible. Thus the following sentence, "The commands of God are steadfast," could be easily read, although written without a vowel, in this manner, The commnds f Gd r stdfst; but every obscurity will be removed if, in general, at least one long vowel be expressed in every word, though in those which are of frequent occurrence, and easily read, this rule may be omitted.

Much has been done to render this short-hand expeditious as well as easily read. By using dots instead of characters for the long vowels, there is a great saving both of time and labour; for, excepting in a very few instances, the vowels occur much more frequently than the consonants. It has been the object of the author also to have all the characters as simple as possible, and to apply the more simple forms to represent those letters which more frequently occur. Thus straight lines, in perpendicular, oblique, and horizontal directions, were first adopted, then a circle, with several of its segments, and afterwards some parts of an oval and oblong figure. Lastly, a few loops were added, to represent the characters which were still wanting; but these loops frequently facilitate the joinings, and in every case are easily formed.

The object in view, in composing this system of short-hand, was to overcome some difficulties, which had been encountered in attempting to learn one of the systems which were then in use; and the end in view has been completely gained, for it is not only easily written, but the author can read that which was done many years ago, as readily as that which was written but a few days ago.

It is now made public for the first time, in the hopes that it will be extensively useful; and this expectation is encouraged by the full approbation which it has met with from several persons to whom it has been communicated, and who now use it in daily practice.

The characters are shown in Plate DXII. Fig. 1.

There is only one dot employed to express the vowels, and that is the round one which marks the period in common reading, and it denotes the different long sounds of the vowels, by a diversity in its position. A dot on a line with the top of a short hand character represents the long sound of *a* as in *shape*, one between the top and middle of the character sounds *ē* long, as in *here;* one at the middle sounds *ī* or *y* long, as in *sigh* or *by*, one between the middle and bottom sounds *ō* long, as in *bone*; and a dot on a line with the bottom of the character sounds *u* long, as in *cube*, or *ū* broad as in *full*. See Plate DXII. Fig. 3, § 1. The vowels of horizontal letters are thus expressed. See Plate DXII. Fig. 3, § 2.

Some of the dipthongs have the same sound as some of the long vowels, and these are to be expressed by the corresponding long vowels. Such as have a compound sound are to be represented by the vowel which is most prevalent in the pronunciation of the dipthong. A dot in the place of *ī* may also stand for by. K is used instead of *g* and *c* hard, and *s* for *c* soft and *z*.

It might be supposed that any of these dots, not being correctly placed in their proper situations, might occasion mistakes in the reading, but no difficulty of this kind is found in practice, as no material error of this sort happens to the expert writer, and when any mistake does occur, the sense of the passage directs the reading. A dot in the cavity of a letter expresses *son*, *sion*, *ac*. See Plate DXII, Fig. 3, § 4. Where there is no cavity either in a single letter, or in the characters combined to form a word, the terminations son, sion, tion, &c., may be written if needful. But words ending in *ation*, *ession*, *ition* or *ution* have these terminations expressed by two dots being put in the place of *ā*, *ē*, *ī*, *ō*, or *ū*. See Plate DXII, Fig. 3, § 5.

Every thing might be written, by the characters, which have already been exhibited; but the additional ones, which are subjoined, greatly shorten, and facilitate writing, and they may easily be acquired and remembered.—See Plate DXII, Fig. 2.

For examples of the following directions see Plate DXII. Fig. 3. § 6. A stroke above a word signifies over, a stroke under a word, implies a repetition of it, and for every repetition of it an additional stroke may be drawn under it; an oblique stroke through a word expresses opposition; the short-hand character for *m* under another character, stands for *dom* or *ment;* the short-hand character for *l* under another short-hand character means *full*, and when written by itself, below the line of the other words, it signifies also full, *e;* the short-hand character for *p*, written below the line, below another short hand character, signifies *ship*, or *shape*, or *shop;* a dot before the short-hand character for *b* means before, and one after signifies behind, and one both before and after, means *before* and *behind*, or *before* and *after*, *g;* a dot by itself, as a character, stands for *a*, *awe*, *O*, *oh*, *owe*. No pointing is made use of but by the comma, as the period mark is otherwise employed, and for the same reason a period is shown in this system of short-hand, by leaving space, two or three times as large as you have between the words, and without any point.

Though there is a character in this short-hand for the letter *r*, yet when immediately following a consonant, it may be more easily formed, by drawing a ray from the side of the consonant, and in cases where this cannot be conveniently done, as in horizontal characters, and the characters for *l*, an inverted touch with the pen, at the end of the character, will be sufficient. When the character for *t* follows an *r*, expressed by a ray from a consonant, it should be formed by drawing the pen upwards in a diagonal direction from the ray. In making the character for *enter*, *inter*, &c. begin with the lower part, and draw the pen upwards, and in the same manner, the character standing for *serve*, *service*, &c. is to be formed.

The long vowel sounds are to be expressed by a dot at the beginning and end of a word, but never in the middle of it; for in that case, you are to begin the next consonant in the place where the vowel should be. This rule could not be strictly complied with in the case of horizontal letters, when the vowels are to be expressed on the upper side of the characters, for this would occasion much awkwardness in the writing, and make one of the characters cut another. To avoid this inconvenience, begin the character which is to stand in the place of *a* or *e*, a little above the horizontal letter, as bearing a reference to the places of these vowels; but so placed as not to touch the other character *m*.

When a consonant is repeated, with a vowel between them, the syllable will be expressed by doubling the size of the consonant. It is oftener more easy and expeditious to denote the plural by a dot under the word, than by adding the character for the plural; but these methods are at the pleasure of the writer. In short-hand, every word is written according to the sound, without regard to the true spelling. You ought never to vary the terminations of the persons of verbs, because omitting these gives much facility to the writing, and cannot embarrass the reading. I forbear from giving many rules for contracting, as every person will form those for himself, so as to be able to follow a speaker, and then only they ought to be freely employed. But when writing such things as are to be kept for private use, and future perusal, I would recommend few contractions, and the regular or general use of the vowel marks.

EXAMPLES IN PLATE DXIII.

The 23d Psalm.

The Lord is my shepherd. I shall not want. He maketh me to lie down in green pastures; he leadeth me beside the still waters. He restoreth my soul, he leadeth me in the paths of righteousness, for his name sake. Yea though I walk through the valley of the shadow of death, I will fear no evil; for thou art with me, thy rod and thy staff they comfort me. Thou preparest a table before me, in the presence of mine enemies; thou anointest my head with oil, my cup runneth over. Surely goodness and mercy shall follow me all the days of my life, and I will dwell in the house of the Lord for ever.

On Speech, from Dr. Blair's Lectures on Rhetoric.

One of the most distinguished privileges which Providence has conferred upon mankind, is the power of communicating their thoughts to one another. Destitute of this power, reason would be a solitary, and in some measure, an unavailing principle. Speech is the great instrument by which man becomes beneficial to man; and it is to the intercourse and transmission of thought, by means of speech and writing, that we are chiefly indebted for the improvement of thought itself.

What we call human reason is not the effort or ability of one, so much as it is the result of the reason of many, arising from the lights mutually communicated, in consequence of discourse and writing. (J. W.)

The preceding article is a literal copy from the Edinburgh edition of this work; the following is furnished from the 8th or stereotype edition of *Gould's American Short-hand.* The author of that work says:

In England and some other parts of Europe, the great utility of this art is now fully acknowledged, and professional gentlemen are beginning to consider it an almost indispensable accomplishment.

In the United States, a land of legislation, public discussion, and universal interchange of thought and word, its manifold advantages are too obvious to require comment, or to demand an apology for the introduction of another article, under the same head.

Although the early history of *short-hand* cannot be traced with entire precision, still it is evident, that under different names and forms, it was practised to some extent by the most remote civilized nations of the earth. The Egyptians. who were at a very early period distinguished for their learning, represented objects, words, and ideas, by hieroglyphics. The Jews also used this species of writing, adding a number of arbitrary characters, for important, solemn, and awful terms, such as God, Jehovah, &c. A similar method was practised by the Greeks; it is said to have been introduced at Nicolai by Xenophon. The Romans adopted the same method; and Ennius, the poet, invented a new system, by which the Notari recorded the language of celebrated orators. He commenced with about 1100 marks of his own invention, to which he afterwards added many more. His plan, as improved by Tyro, was held in high estimation by the Romans. Titus Vespasian was remarkably fond of short-hand; he considered it not only convenient and useful, but ranked its practice among his most interesting amusements.

Plutarch tells us, that the celebrated speech of Cato, relative to the Catalinian conspiracy, was taken and preserved in short-hand. We are likewise informed, that Seneca made use of a system of short-hand writing, which consisted in the use of about 5000 characters.

The first publication upon the subject, of which we have any correct information, was about the year 1500, from a Latin manuscript, dated 1412. Various other publications followed in succession, without materially advancing or changing its character, till about the commencement of the 18th century; nor were the principles, till many years afterwards, settled upon a basis which could insure stability to the art.

Byrom was the first who treated the subject scientifically, and to him we are indebted for the promulgation of those fundamental principles, which will ever constitute the true foundation of every rational system of stenography. His first edition appeared in the year 1767, previous to which, many systems had been published under the name of short, or swift-hand, which were so involved in philological refinements, or superfluous arbitrary signs, as to be more tedious in the acquirement and practice, than the usual long hand, and scarcely intelligible, except to the inventors, or those who devoted their lives to practice it. Nor did Byrom rest, till he had much obscured the merits of his original plan by the introduction of numerous grammar rules, plausible in theory, but useless in practice. Much difficulty was experienced by him and later writers, in selecting appropriate characters, and assigning their respective functions; but a still greater difficulty by learners, from the too frequent introduction of arbitrary signs, and subtle theories, which have rendered useless to the world much that was otherwise valuable, in the elementary principles of Byrom and his successors.

Books upon short-hand have been rendered voluminous, intricate, and expensive, by theoretical niceties, which serve only to discourage the learner, to keep the art from schools and colleges, and thus prevent its general extension and usefulness.

Under these circumstances, few individuals have been successful in acquiring a knowledge of the subject; and while these have generally found an interest in suppressing its dissemination, the multitude have ignorantly rejected it, as a mystic and useless art. This neglect was just, while confined to some of the ponderous volumes of crude and unintelligible hieroglyphics, which appeared between the 16th and 18th centuries, but when applied to the more improved systems of a later date, it is grossly illiberal and unjust. Still, the prejudices excited previous to the publication of those scientific principles, which now characterize the art, are unjustly kept up, by those who are more ready to condemn what they do not understand, than to acknowledge their ignorance of a subject with which others are familiar.

Under these embarrassments, the subject received, comparatively, little attention in the United States, till within the last few years; and there are many yet unaware of the simplicity and practicability of the art, or of the facility with which it may be acquired.

Without descending to other particulars, it may be remarked, that since the appearance of Byrom's system, not less than one hundred treatises have been published, in the English language, besides a number of elaborate works in French, German, and other languages,—each professing superiority over all that had preceded; but, in fact, adding little to which the term improvement can be justly applied.

The most distinguished English writers upon this subject are the following, viz. Addy, Aldridge, Angell, Annet, Blandmore, Blosset, Botly, Bridges, BYROM, Coles, Cross, Dix, Everardt, Ewen, Facey, Farthing, Gibbs, Graime, GURNEY, Heath, Holdsworth, Hopkins, Jeake, Labourer, Lane, Lyle, Macauley, *Mason*, MAVOR, Metcalf, Nicholas, Palmer, *Rich*, Ridpath, Shelton, Steel, Turner, TAYLOR, Thickness, Tiffin, Webster, *Weston*, Williamson, Wills, and Willis.

The systems now principally used in England, Ireland, and Scotland, are those of Byrom, Mavor, Taylor, and Gurney. In the United States, *Gould's System* has nearly superseded all others, and may be pronounced the standard of American Stenography. This plan combines within narrow limits the practical merits of the four last mentioned systems, and appears to be peculiarly adapted, not only to the genius of our language, but to the present condition of the American people—being more concise and less expensive; and at the same time adequate to all the demands of literature, arts and sciences, so rapidly spreading through this mighty empire of independent communities.

We shall, by permission, present our readers with an abstract of the theory of this system, as taught by the author in the principal cities and colleges of the United States, practised by him in courts of justice and legislative bodies, and recently illustrated by a series of lectures published in "*The American Repertory* of arts, sciences, and useful literature," vol. i.

We shall also exhibit a fac simile of the author's hand, in an entire copy of the Declaration of American Independence (see Plate DXIII, No. 2).

In the introduction to this system the author remarks, it is his aim to adapt his work to the age in which we live; to lay aside every thing *unnecessary*, and to express in few words *all that is necessary* for a general system of short-hand.

He asks, would our common writing be more easily acquired, or its execution in any way facilitated, by increasing the number of letters in the English alphabet? Would arithmetic be improved by the introduction of arbitrary marks to represent the numbers 11, 12, 13, and so on to 100 or 1000? Would the art of printing be rendered more simple, easy, and expeditious, by the construction and use of leaden syllables, words, and sentences, instead of the letters of which they are composed?

Till these questions can be answered in the affirmative, the following theory will be found, *with practice*, amply sufficient for the purposes proposed, and *without practice* the efforts of human invention will prove abortive.

To convey a more just idea of the present state of the art, it is necessary to speak of earlier systems. This recapitulation will enable us to appreciate more fully the triumph of modern improvement over the rude attempts of former times; while it will furnish a reasonable ground of hope, that a general standard of stenography may yet be established, notwithstanding numerous attempts have proved abortive.

Short-hand formerly consisted in the use of almost innumerable hieroglyphics and arbitrary characters, which could only be learned with much time and labour, and when learned could not be retained without continual practice. This was tolerable only while words were few, and the cultivation of the human mind in its infancy. For however numerous these characters, the advancement of arts, sciences, and general knowledge, rendered a continual multiplication necessary to the representation of new words and ideas; nor could such a system, by the constant aid of human invention, even approximate perfection, while resting on this false foundation. Every appendage to the already overgrown structure, only served to make it more unwieldy, and to hasten the downfall of the whole fabric; for the characters were some of them so seldom used, that the utmost powers of human memory could scarcely retain them, and if recalled by memory, it could not be with sufficient facility to answer the end for which they were intended.

We have thus far traced the subject as an art merely—we will now proceed to unfold some of its beauties *as a science and an art*.

We are all aware, that ten simple figures, or the nine digits and cipher, have been found sufficient for all the purposes of numerical calculation. We also understand, that these ten figures are now used for nearly the same object, by every civilized nation on earth. We likewise know, that seven notes comprise the whole of written music, and that by a proper arrangement of these few notes, may be intelligibly represented all the varieties of harmony. It is also known, that, by means of these few simple, but acknowledged signs, this music is transmitted from individual to individual, and from nation to nation; requiring little interpretation but that afforded by the visible signs themselves. And though individuals are antipodes, totally ignorant of each other's language,—discordant in all their other feelings, habits, and views, yet, in the signification and use of musical signs, they have not only a perfect understanding, but hold communion, at the distance of thousands of miles, and reciprocally drink, as it were, from the same fountain, the rich melody of borrowed sounds with which the ear and heart had never before been greeted.

It is also evident, that, notwithstanding the infinite number of combinations, produced by the organs of speech, and the varied modifications of the human voice, the whole may, for all the purposes of short writing, be resolved into a few prominent sounds. Hence the practicability of assigning to each sound a particular representative, which shall be understood like arithmetical figures, or musical signs, by all people, and at all times, without regard to the language in which they are employed.

As a proof of this position, to a most satisfactory extent, let us look to the 26 letters of our common English alphabet. We all know, that with these few signs may be recorded the language of a thousand tongues for a thousand ages: nor would the object be at all facilitated were the signs 26 hundred, or as many thousands, though the modes of expression are beyond all human computation.

It is also a fact of notoriety and philosophic interest, that our alphabetic signs are now employed in common by the inhabitants of England, France, Spain, Italy, and many other countries.

By these facts we see, that the powers of arithmetical figures, musical signs, and alphabetic letters, are alike unlimited, in the extent of their application. Having established this important fact respecting the use of sounds and visible signs, we may with propriety approach the subject in question.

The system of short-hand which is about to claim our attention, *is not*, as some have erroneously imagined, an arbitrary art, necessarily confined to the indefatigable reporter of speeches—it is in fact a *science* as well as an *art*; and as such, claims a degree of attention even from those who may never employ it as an *art*.

As a science, adapted to the powers and faculties of the human voice and human ear, it determines upon the use of alphabetic characters, for the purpose of swift writing, instead of arbitrary signs for words, sentences, or ideas.

In the next place, it furnishes rules, which, if reduced to practice, will enable us to record language with the least possible time, labour, and space; compatible with legibility.

It shows the common alphabet to be totally at variance with the primary object of *short-hand*, which is *despatch*—that several of the letters are superfluous, and none of them well chosen, as they contain unnecessary crooks and curves, which tend to perplex and embarrass the learner, while they require time and space, to the sacrifice of ease and facility.

In this system, the alphabet consists of twenty characters, which are extremely simple, easily made, and readily combined, without loss of time, labour, space, or legibility, They are employed, 1st. To represent, individually, certain words, which are known to occur very frequently. 2d. As letters, or representatives of sounds, to be joined together in writing all words not denoted by individual characters. 3d. For some of the most frequent prefixes; and 4th. For the most frequent terminations of words.

There is a symmetry not only in the adaptation of these *visible signs* to each other, so as to insure the greatest brevity, perspicuity, simplicity, and beauty; but the elementary *rules* harmonize with each other and the whole, according to fixed scientific principles.

The learner should not be discouraged, though he be not able at once to record the entire language of a fluent speaker; nor should he hence infer, that the system is incomplete, or the art unattainable: for with the same propriety might the young reader condemn and abandon the use of the common alphabet, because he cannot at once read elegantly,—the musician his notes, or the Tyro in mathematics his Elements of Euclid: let him persevere in practice, and he will soon attain the object of pursuit.

To turn this necessary practice to the best possible account, he should record in a common place book from day to day such facts and other items of information, as may be considered immediately interesting, or worthy of future perusal. At first, his notes should be read while the subject is familiar, and by this course, the writing and reading of short-hand may in a few days be made easy, useful, and amusing, while the art cannot fail to become a potent labour and time-saving engine, not only for the actual accumulation and preservation of knowledge, but for the cultivation and expansion of the mind, and improvement of the memory. For by judicious exercise, this faculty can be trained to receive more and retain longer, whatever may be worthy of its attention.

This improvement, however, does not depend on the substitution of one faculty for another, but on their mutual co-operation, as auxiliary, each to the other. For though we are able by short-hand to preserve a literal copy of any particular subject, for our gratification and instruction, thereby increasing our stock of tangible knowledge; yet, if memory be left to languish in sickly inactivity, and thus gradually lose its energies or become enervated for the want of proper exercise, the loss is equal to the gain.

The memory, then, while it should not be overburdened with unnecessary verbiage, should never be released from that habitual exertion on which its own preservation and usefulness depend; the great secret of preserving and improving the memory consists in giving it a sufficient quantity of the right kind of aliment, affording due time for its digestion, and no more relaxation than is absolutely necessary to its health and vigour.

The person who can write rapidly does not consequently substitute writing for memory, but employs it as an assistant; and every person when committing words to paper for his future use and improvement, should endeavour to fix in memory, at least the leading features of the subject, depending on short-band, only for that which memory cannot recall.

When the memory is thus properly exercised, it cannot fail to be improved; and the mind, being released from the unnecessary incumbrance of words, will find more time to grow and expand, by reflecting, or comparing and analyzing the ideas which words may have infused; for the memory should be rather the repository of ideas than of words, which are the mere vehicles of thought, and always at hand.

Although the following system is in itself complete, so far as intended for correspondence and general use; yet, for the gratification of those who wish to make other abridgements, and particularly those of the learned professions, who think proper to engraft upon the established system certain technical or other abbreviations, adapted to their own respective professions, the following hints may be useful.

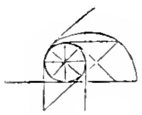
The lawyer or judge may, with much propriety, even if writing short-hand, substitute in place of certain words which occur very frequently, the initial common hand letter, as P, for plaintiff, D. for defendant, W. for witness, C. for court, T. for testimony, V. for verdict, J. for judgment, &c.

The physician may, with like propriety, use P. for patient, pulse, or perspiration, F. for fever, I. for inflammation, R. for respiration, &c.

The clergyman may find it convenient to use H. for heart, or heaven, S. for sinner or salvation, R. for redemption or resurrection, J. for judgment, C. for conscience, condemnation, &c.

Young gentlemen who attend lectures on chemistry, anatomy, or other subjects, may save much labour and time, by using the initials of certain technical terms, which occur frequently in the course of their study.

EXPLANATION OF THE SYSTEM.



This diagram exhibits at once, all the characters employed in this system; they are 20 in number, and of four distinct species, viz.

1. The right line.
2. The semicircle.
3. The circle and line combined.
4. The quarter circle and line combined.

1. The horizontal diameter is used for the letter s; the perpendicular diameter for t; the oblique diameter, drawn downwards on an angle of 45°, to the left, is d; the same line running upwards is r; the oblique diameter drawn downwards on an angle of 45° to the right, is f, or v, either, as may be required.

2. If a circle be divided horizontally, into two semicircles, the upper one is k, or q; the lower one, n: if divided perpendicularly, the left semicircle is ch, and the right g, or j.

3. If any of the right lines above described be joined to a small circle, and project as a tangent, the circle and line together form a stenographic letter of the third class, as seen upon the third limb of the tree, viz.—If it project from the top of the circle, to the *right*, *horizontally*, the circle and right line together constitute the letter m. If the same figure be turned, so that the tangent project *downward*, *perpendicularly*, from the *right side*, it will represent the letter p—if *obliquely* to the *left*, *downward*, on an angle of 45°, it is h—if *obliquely* to the *right*, *downward*, on the same angle, it is b; if *obliquely* to the *right*, *upward*, it is l; or, if the *upper* segment of a larger circle be joined to the *whole circle*, in the form of a curved tangent, projecting to the *right*, the letter w is produced.

By joining the *right line* to a *quarter*, instead of the *whole*, or *half circle*, the letters of the fourth class, are respectively produced—viz. If the right line be joined as a tangent to that segment or quadrant of the circle, lying *below* the horizontal diameter, and on the *left* of the *perpendicular*, and project to the *right*, *horizontally*, it produces the letter x;—If attached to the upper quadrant, on the *left* of the *perpendicular*, and project *horizontally* to the *right*, the character sh is formed—if attached to the other extremity of the same quadrant, and project from the *left side* of the circle, *perpendicularly down*, it is th—if attached to that segment or quadrant, contained between the lower extremities of the two *oblique diameters* in the diagram, and be extended *obliquely upward* to the *right*, on an angle of 45°, it is the character y—and if a *horizontal right line*, be drawn from *left* to *right*, till it strike the lower edge of the circle, and be joined to the *lower quadrant*, on the *right* of the *perpendicular*, the character ious is produced.

These characters have a fourfold application.

1. To represent, individually, a few common words.
2. The most frequent prefixes.
3. The most frequent terminations.
4. The alphabetic letters, for which they have been substituted.

ALPHABET AND COMMON WORDS.*

	· ☞	*a e i o u y*
1. Right Line.	— *s*	*is as us his*
	| *t*	*into unto it*
	/ *d*	*do did done*
	/ *r*	*are our or*
	\ *f v*	*of off if*
2. Semicircle.	⌒ *k q*	*know knew known*
	◡ *n*	*and an in*
	(*ch*	*such chance church*
	) *g j*	*God good give*
3. Circle and Line.	*m*	*me my many*
	p	*peace person power*
	h	*have he had*
	b	*be by been*
	l	*lord all love*
4. Quadrant and Line.	*w*	*with which who*
	x	*example except accept*
	sh	*shall shalt should*
	th	*the they that*
	y	*you your year*
	ious	*conscious judicious*

* The words above are always represented by single characters, and will constitute about one third of any common discourse; all other words are spelt according to their sound, and written with the characters of the Stenographic alphabet, having the power of letters only. The vowels a, e, i, o, u, y, are represented by a dot.

Rules for making the Characters.

1st Class.—Make s to the right, t down, d downward, r upward, f v downward.

2d Class.—Make k q and n from left to right, ch and g j downward.

3d Class.—Make the circle first in all cases.

4th Class.—Make the hook or quadrant first in all cases, except ious, this always ends with the hook. ☞ For double letters make the line longer, or the circle larger.

Rules for joining Characters.

Make one letter as if no other were to be made, and then without lifting the pen, make the next as if the first had not been made, observing to turn in that way which is most simple and easy, but let the line always take the same direction from the circle.

Rules for Spelling.

1. Use no vowels in spelling, except when distinctly sounded at the beginning and end of words. Example: entity ntt, chastity chstt, obey oba, away awa, pay pa, lay la, say sa.

2. Omit all silent letters. *Ex.* Light lit, sight sit, night nit.

3. When two letters sound like any one, use that one in their stead. *Ex.* Laugh lauf, physic fysic, Utica Utk, empty mt.

4. The letter c must be supplied by k and s. *Ex.* Comply komply, celestial selestial, receiver resciver.

5. H may frequently be omitted as follows. *Ex.* Behold beold, how ow, highway iway, heaven even, help elp.

6. Ph and gh are never written in short hand, being always sounded like f or v (when not silent), and therefore represented by these characters. *Ex.* Enough enuf, tough tuf, Philadelphia Filadelfia, philosophy filosofy, Stephen Steven.

7. When double consonants occur, use only one; but if a vowel intervene, use both. *Ex.* Restlessness restlesnes, commendation comendation, memory mmory, people pple.

8. B and w may be omitted, as follows. *Ex.* Number numer, encumber encumer, slumber slumer, answer anser.

9. The ch character is used only where it has its natural sound, as in charm, church, chapter, choice. Where ch have the sound of k or sh, let these signs be used.

10. Let z be represented by s in all cases; but to distinguish it, let the mark be made thicker than for s.

REMARKS.—Although this method of spelling may appear difficult to the beginner, he is assured, that it may be made quite familiar in a few hours, and that without injuring his common spelling. To do this, pronounce words distinctly and rapidly, retaining for short hand nothing but the most prominent sounds; as nv, for envy; ntt, for entity; ldr, for elder; flsfr, for philosopher, &c.

Rules for Writing.

1. Provide a good pencil, or fine hard pen, good ink and paper.

2. When a vowel is to be written make a small dot, and if it belong to a particular word, let it stand near that word, at the right or left.

3. Do not lift the pen in a word, except to write a prefix, termination, or vowel.

4. Make the *character* y, for the words *you*, *your*, *year;* and at the *beginning* of words, but never at the last end, as it is there a vowel and represented by a dot.

5. *Prefixes, &c.* At the beginning of words use r for *recon*, *recom;* m for *multi*, *magni;* k for *contra*, *contri*, *counter;* n for *inter*, *intro*, *enter;* s for *satis*, *super*, *circum*; t for *trans.* It must be remembered, that all these signs should be made small, and placed just before the word, but not joined to it. For *under*, *beneath*, *below*, make a small circle ₒ below the line of writing; for *on*, *upon*, *over*, and *above*, make it ° *over* the line; for *before* make it in the line °; for *up* and *down* make a small dot or touch above· or below. as the case requires.

6. *Terminations.* At the end of words a scratch through the last letter is *tive;* a dot. below is *ly*; a dot˙ above is *tion*, *sion*, *cian*; a touch′ above is *tions*, *sions*, *cians*; at the right it is *ing*, *ong*, *ung*; if below, it is *ings*, *ongs*, *ungs;* if thus` it is *ity*, *ality*, *elity*, *ility;* a horizontal touch¯above is *al*, *ial*, *tial*, *cial:* and the same touch_ below is *less*, *fess*, *ress;* and without lifting the pen, the following letters may be used for some of the frequent endings of words; viz. n for *ness*, b for *ble* or *bles*, m for *ment* or *ments*, s for *self* or *selves*, f for *full*, *ference*, w for *ward*, sh for *ship*, and ⁀ for *ious*, *eous*, *uous*, *ius.*

7. Use common figures to represent numbers, but make them larger than the other characters, that they may be readily distinguished.

8. The common marks for punctuation may all be used in short hand, except the period, which would be taken for a vowel. But the following distinction is all that is necessary in following a speaker—when a sentence is complete, leave a blank of half an inch, and let each paragraph begin a line.

9. Long words may often be represented by two or three of their leading consonants, or by their initials, when the sense is clear; and in most long sentences a number of small words may be dropped, without impairing the sense.

10. When a word or sentence is immediately repeated, write it once, and draw a line under it for the repetition. If it be a sentence, and not repeated till something else occur, write a word or two and make the ⟍ for &c.

Rules to improve Legibility.

1st. As a, I, O, are the only vowels ever used alone, they may be easily distinguished as follows, ˙a ·i .o; that is a above, I in the centre, and O below, the line of writing.

2d. At the beginning and end of words make use of the same distinctions, ˙a or e ·i or y .o or u

3d. To show certain omitted vowels in the middle of words, place a comma over the word as follows, thus: ,for a or e ———; - for i or y ———; ‘for o or u ———.

4th. For diphthongal sounds place the comma under the word, as follows, — for ou; and — for oy.

5th. In doubtful cases, let {d, v, q, g} be made heavier than {r, f, k, j}

Rule for Reading.

When a word is not known at sight, proceed to speak each letter of which it is composed, separately and distinctly, and then pronounce the whole together, as rapidly as possible—thus; n, v, when pronounced nv, would give the word envy—n, t, t, pronounced ntt, would give the word entity—l, d, r, would be elder—f, l, s, f, r, or flsfr, would be readily recognized as philosopher; and the same of all other words.

REMARK.—The characters of this system are simple and few, and may soon be known at sight, like the letters of our common alphabet, and when thus familiar, the sense of the subject will render the reading sure and easy.

Much might be said on the subject of omissions and contractions, but as these must after all depend more upon the practical experience of the writer than upon any written rules, I shall simply quote from a former edition of the Edinburgh Encyclopedia, from

Rees's Cyclopedia, and the Encyclopedia Brittannica, the rules of Byrom and Mavor. Upon this subject Byrom says, "It may be proper to advise the learner, not to embarrass himself with short-hand abbreviations, till by a competent practice of writing, according to the rules already laid down, he is become so well acquainted with the characters, as to be able to write and read them with nearly as much ease as common long hand. He will then meet with little more difficulty in reading words contracted, than he formerly did in those written more at length, provided that the rules of abbreviation be duly attended to. A summary of the principal rules and most practical methods of abbreviation is here given, and it is left to the skill and discretion of the writer, by observing their nature, and proceeding upon the same principles, to make such other advances and improvements as his occasion may require."

Before I proceed to the rules, I will subjoin another extract. "Lambinet (a French writer), in his 'Researches upon Printing,' observes, that modern stenography, which, like the telegraph, dates in France from the foundation of the republic, has neither the inconvenience, nor the obscurity, nor the danger of the ancients. The old characters varied under the hand of the copiers, and the sense changed according to the genius of the interpreters; so that their contractions are become so many enigmas, because we can refer to no other copies to ascertain the true reading, and because the authors are no longer in existence. But," continues the writer, "by the present system of stenography, the writers follow the words of the public orators, take down their speeches, the motions, the debates of the tribune, or the lectures of the professors of the Lyceum, and produce a literal translation at last, in the usual characters and in print."

A brief Summary of Byrom's Rules of Abbreviation from the Encyclopedia Brittanica.

Rule 1.—To join the auxiliary verbs, the particle *not*, and the pronouns together; as *can be, have been, must be, cannot be, he must be, ought not to be, &c.*

Rule 2.—To join the marks in an unusual manner, in order to show that each particular mark denotes a word, and not a single letter; as *in the, it is, as it is, since it is, it was, it was not to be, &c.*

Rule 3.—Derivative substantives may be very conveniently represented, by placing a point at the end of the words from which they are derived. Derivative adjectives and adverbs may be represented also by points, distinguishable by their situation, both from the substantive and the vowel points; which may be done by placing them in a line, which, if produced, would pass through the substantive point, and would also be perpendicular to the last consonant mark; one placed *before* the substantive point, signifying the adjective, one *after* it, the adverb: as, *forgetful, forgetfulness, forgetfully; reasonable, reasonableness, reasonably; sufficient, sufficiency, sufficiently.*

No great accuracy is necessary with respect to the adjective and adverb points, provided they be placed so as to be clearly distinguished from the vowel and substantive points.

Rule 4.—Such words as, either by their particular relation to the subject, or frequent occurrence, are easily discoverable, however concisely written, may be denoted by the first letter, if they begin with a consonant, if not, by the first vowel and consonant, with the adjective, substantive, or adverb point annexed; as "life and *immortality* are brought to light by the *gospel*;" the "*resurrection* of the dead, and a future state of *rewards* and *punishments*, are plainly and positively taught in the gospel." The adjectives which usually accompany such substantives may also be denoted by their first consonant, joined to the substantive; as, "with *humble submission* to your lordship."

Most writers of short-hand accustom themselves to mark such words as most frequently occur in their own particular professions, by the initial letters only, with the substantive, adjective, and adverb points, which, through custom, easily suggest those words to them at first sight. But it must not be understood, that those marks imply those words exclusively, and no other. They may stand for any other beginning with the same letters, which the sense of the passages necessarily requires.

Rule 5.—A dot placed at the point of concurrence of two consonant marks, denotes two substantives, of which those marks are the first consonants; and also that the latter is governed of, or connected to the former by some preposition, which is omitted; as, "the *love of money* is the root of all evil;" "seek ye first the *kingdom of God*, and his righteousness," &c.; "the effects of gravity are visible in every part of that system to which we belong, but the *cause of gravity* still remains undiscovered."

And if an adjective precedes either of the substantives, they may all three be represented by their first consonants joined together, with the dot always placed at the end of the first substantive: as, "the *great goodness of God* is manifest in all his dealings with his creatures;" "his majesty the *king of Great Britain.*"

Rule 6.—The substantive point, placed before a single consonant mark, denotes that the substantive is to be repeated, with some intervening preposition; as, "*day after day*;" "from *time to time*."

Rule 7.—The substantive, adjective, or adverb point, placed before two or more consonant marks joined together, denotes two or more substantives, adjectives, or adverbs, of which those marks are the first consonants, and also that they are connected by a conjunction; as, "the precepts both of *natural and revealed* religion forbid us to do our neighbours any injury:" "what doth the Lord thy God require of thee, but to live *soberly, righteously, and godly* in this present world."

Rule 8.—Many long words, especially those in which the marks for the consonants will not join neatly, may be denoted by their first syllable, with as many points annexed as there are syllables wanting; as *multitude, correspondence.* And when great despatch is required, the points may be omitted, especially if the words do not begin with prepositions; as, *signification, difficulty, negligence.*

Rule 9.—Words beginning with prepositions may be denoted by their respective prepositions, together with the next consonant and vowel, and sometimes with the next consonant only, adding, when necessary, the substantive, adjective, or adverb point; as, *deliberate, transmutation, recommendation, consanguinity*, &c.

The participles may be abbreviated after the same manner, by adding, instead of the points, the terminations *-ing* or *-ed* to the latter consonant mark; as, *considering*, *considered*.

Words beginning with double or treble prepositions, may be written after the same manner, joining the prepositions together; as, *representation*, *misrepresentation*, *incomprehensibility*. If two consonants begin the next syllable, the writing of them both will help to discover the remainder of the word; as, *misunderstanding*, *transubstantiation*.

Rule 10.—Words ending in any of the terminations, which in the alphabet are denoted by consonant marks, may be expressed by their first consonant and vowel, together with the proper mark for its termination; as, *arbitrary*, *opportunity*, *curiosity*, *lawfulness*.

Rule 11.—Such words as are easily discoverable by the particular prepositions which they require, may be denoted by their first consonant only; as, "this *belongs* to me;" "he made some good *observations* upon it;" "we must *guard* against such passions as we are most *liable* to."

As few English words end with the syllable *-to*, the preposition *to* may be joined to the preceding word, which is signified by its first consonant only; as, this *belongs to* me, *liable to*, *satisfactory to*.

Other prepositions which are denoted in the alphabet by a single consonant may, in like manner, be joined to the preceding word; as, "he made some good *observations upon* it."

Rule 12.—Prepositions generally require after them either a noun or pronoun. The pronouns being few in number, and used as substitutes for nouns, must occur very frequently, and by that means soon become familiar to the learner; pronouns, therefore, may be joined to the prepositions, without danger of creating any difficulty to the reader; as *to me*, *to my*, *to you*.

Rule 13.—The preceding word, the preposition, and pronoun, may be joined all together; as *belongs to me*, *extends to us*, *agreed with me*, *depend upon me*, *observations upon this*.

The words *some*, *any*, *none*, *which*, *each*, *both*, followed by a preposition and pronoun, may be denoted by their first consonants, and may be joined to the preposition and pronoun; as, *some of them*, *any of us*.

Rule 14.—The adverbs preceding the verbs, and the substantives following the pronominal adjectives, may be joined to the verbs and adjectives respectively, denoting both the adverbs and substantives by their first consonants, or at most by their first consonants and vowels; as, "you may *safely depend upon my word*."

Rule 15.—Many common phrases, formed by a substantive preceded by the prepositions *with*, *without*, *in*, &c., and followed by *to*, *of*, &c. may be very conveniently abbreviated; as, *with regard*, *respect*, or *reference to*, *in order to*, *in consequence*, *comparison*, or *consideration of*.

Rule 16.—Common adverbial phrases are, in like manner, often denoted by their initial consonants joined together; as, *at the same time*, *at present*, *in this manner*, *in like manner*, *in a great measure*, *in the same manner*, *in the mean time*, *in general*, *in particular*.

And when the proportion of equality is expressed, with some one word intervening, they may be all joined together; as, *so much as*, *as well as*, *as soon as*.

Rule 17.—The contractions which may be made, when *it is* or *it was*, are followed by an adjective, and *to* or *that*, are very numerous; as *it is impossible to*, *it was unnecessary to*, *it is contrary to*, *it is according to*.

I now proceed (says the American author) to give a few of the rules of abbreviation laid down by Dr. Mavor, and published in a former edition of the Edinburgh Encyclopedia; from which, with the other authorities already quoted, and the examples that I shall hereafter furnish, the learner will be prepared to make such advances in the reduction of labour as he may deem expedient, without endangering the usefulness of the previously acquired system.

"The value of stenography, says the editor, is not unknown to the learned; and the ease and success with which it has been lately cultivated in these kingdoms will, in all probability, soon render it an object of general attention. No one, however, appears to us to have simplified and improved the art so much as Dr. Mavor, author of the Universal Stenography, who has liberally permitted us to present our readers with a complete view of his scheme; which, in many schools of the first reputation, now stands a deserved class-book."

Having given an outline of his theory, Dr. Mavor proceeds :—

"Though a more concise method of writing, or more numerous abbreviations, may not be indispensably necessary, if the foregoing directions be practised for a considerable time, yet contractions will be found extremely useful and convenient to those who have attained a proper knowledge of the subject, and lead to a greater degree of expedition, at the same time that they diminish the labour of writing. It has been observed in the introduction, that abbreviations are only to be employed by proficients in this art ; because expedition is not the first, though the ultimate object in view : and that an easy legibility is of the utmost consequence to the learner, which, however, cannot be preserved, if he adopts too soon those very rules, which in time will afford him the greatest ease when applied with judgment.

"The following short and practical rules will be found, we hope, fully adequate to every purpose for which they were intended.

"Rule 1st. The usual abbreviations in long-hand are always to be followed ; as Mr. for Master, M.D. for Doctor of Physic, and Abp. for Archbishop, &c.

"Rule 2d. Substantives, adjectives, verbs and participles, when the sense will direct to the meaning, are to be expressed by their initial consonant with their distinguishing marks ; viz. a substantive must have the dot exactly over its initial consonant ; an adjective must have a dot under it ; a verb is to be expressed by a comma over its initial consonant ; and a participle by a comma under. These being the four principal parts of speech will be sufficient ; and an adept will never be at a loss to know when he can with safety apply this rule to them.

"Rule 3d. To render the writing more legible, the last letter of the word may be joined to the first, and the proper mark applied.

"Rule 4th. The constituent or radical part of words, especially if they are long, will often serve for the whole, or sometimes the first syllable; as we ought to moderate our *ex.* by our *circum.*; a man's *man.* commonly shape his *for.*

"Rule 5th. All long words, without exception, may have their prepositions or terminations expressed by the incipient consonant of such preposition or termination.

"Rule 6th. When there is a great dependence between the parts of a sentence, the initial letter will often suffice; as L. is the capital of Great B. The eldest son of the king of Great B. is styled prince of W. Every one, it is presumed, will allow this to be perfectly legible in long hand [particularly in Engand], then why should it not be in stenography?"

Although I decidedly reprobate the use of numerous arbitrary signs, as heretofore employed in short hand, still to a limited extent, they may be useful. Mr. Gurney, a celebrated reporter in the British parliament in his own work upon short-hand, when speaking of arbitrary characters, says:

"A principal advantage in this system of short-hand consists in the small number of arbitrary and contracted characters; and in their conspicuity, by which they will be soon understood, fixed in the memory, and read again at first sight."

He afterwards introduces the capital letters of the common writing alphabet, as the arbitrary signs of certain words of frequent occurrence—the plan I think a good one, if confined within proper limits; and I therefore give it as prepared by him, together with remarks and additions by the editor of the last American edition of his work.

ARBITRARY CHARACTERS FORMED FROM THE WRITING ALPHABET.

☞ *The italic types are used as most convenient to represent the common writing letters.*

A Administrator, -tion	*a* accord -ing -ingly
B	*b* bankrupt -cy
C Congress, Congressional	*c* circum -stance -es
D Demonstrate -tion	*d* evident -ly, evidence
E Ecclesiastic -al	*e* establish -ed -ment

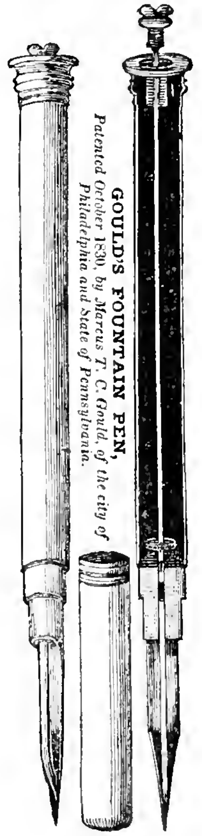
U United States	*u* unlawful -ly -ness [ation
V	*v*
W	*w* witness -es -ing
X Christianity	*x* extraordinary -ly
Y	*y*
Z	*z*

STENOGRAPHIC PEN, BY M. T. C. GOULD.



This instrument being chiefly employed in Stenographic writing, and invented by the author of the preceding system of Short-hand, may be very properly appended to this article.

The following is a full and exact description of the parts, construction and use, of the Perennial or Self-supplying Fountain Pen:

1st. A cylindrical barrel, of gold, silver, glass, or other material, about five inches in length, and one third of an inch in diameter, to be filled with ink.

2d. A shaft of metal or other substance screwed into the lower end of the barrel, and projecting downward below it, about half an inch, forming in its diminished size, a collet upon which is slid a common or metallic pen.

3d. A small tube or conductor, of gold, silver, or other material, passing upward through the collet, and communicating with the column of ink by means of a regulator, hereafter described, and at the same time extending downward, along the centre of the pen, with the lower end so bent as to open directly upon the split of the pen.

4th. A hollow wire, or rod, called the regulator, passing through the upper end of the barrel, and extending downward through the barrel and shaft, till it meets the ink tube, about midway of the shaft and collet. This regulator has a small groove or other opening near each end (and within the fastening or packing box, at each end of the barrel), for the purpose of admitting, when unscrewed, ink below, and air above—that is, ink into the tube below, and air into the barrel above; and at the same time, opening an uninterrupted channel the whole length of the instrument, through which, if the regulator be screwed down and opened above, air or water may be forced, for the purpose of cleansing the tube, without communicating with the ink in the barrel.

5th. A piece of sponge or other porous substance attached to the wire, immediately above the shaft, and filling the entire diameter of the barrel, about a quarter of an inch upward—thus forming, when the regulator is unscrewed, and the pen in use, a strainer of the ink, and a regulator of its flowing; or, when screwed down, and the pen at rest, a general valve upon which the whole column of ink may rest. Immediately above this spongy substance is attached to the rod, a thin, flat, circular plate, or follower, equal in width to the inner diameter of the barrel; this plate should be finely perforated in various places, near its circumference.

6th. A small stopper, at the upper end of the regulator, and a suitable cap at the lower end of the barrel, give a finish to the whole instrument.

When in proper order, this pen will write for hours, supplying itself with ink as fast as desired by the writer.

STEREOGRAPHIC Projection of the Sphere. See Geography, Vol. IX. p. 622.

STEREOTYPE Printing. See Printing, Vol. XVI. p. 156.

STERNE, Lawrence, a celebrated writer, was born at Clonmell in Ireland in Nov. 1713. He received his education at Halifax, from which he went to Jesus College, Cambridge. In 1759 he published his *Life and Opinions of Tristram Shandy*, in 2 vols. which were followed by seven more, the last of which came out in 1766, and in 1768 appeared his *Sentimental Journey*, in 2 vols.; he published also 4 vols. of Sermons, two in 1760 and other two in 1766. He died in March 1768 at the age of 55, leaving behind him a widow and a daughter. This daughter, who married a French gentleman, published in 1775 a collection of her father's Letters in 3 vols. 12mo., preceded by Memoirs of his Life and Family. His private and domestic character were such as might have been expected from a clergyman, who, at the age of serious thought, had published works so questionable in point of morality and decorum.

STETTIN, a town of Russia, and the capital of Pomerania, is situated on an eminence upon the left bank of the Oder, about sixty miles from the Baltic. It is connected by a long bridge over the largest of the four streams into which the Oder is here divided, with Lastadie a part of the town. It has three suburbs, five gates, and several squares. The largest of these is a fine square containing a pedestrian statue of Frederic II. by Schadow. Many of the houses in the town are very elegant, and some approaching even to palaces. The principal public buildings are the castle, the government house, the arsenal, the barracks, the exchange, the public library, the theatre, the hospitals, an academical gymnasium, a school of navigation, and five parish churches. The gymnasium is conducted by several professors, with assistants, who give lectures in theology, philosophy, medicine, law, mathematics, and languages both ancient and modern.

The principal manufactures of Stettin are woollen, linen, and cotton goods, leather, soap, tobacco, ships' anchors, ships and boats. Stettin is the outlet of the manufactures of Silesia, and also part of Brandenburg and Poland, and hence it enjoys a very considerable trade. Its exports are chiefly grain and timber. The wheat is inferior to that of Dantzic and Elbing, but it is cheaper. The oak timber and stone of Pomerania are much esteemed. The imports are coffee, sugar, dyewood, rice, rum, cotton-wool, and Buenos Ayres hides. In 1816 the number of ships engaged in the export trade were 984, and in the import trade 1311. All vessels which draw above seven feet of water are obliged to load and unload at Swinemunde, a small town situated at the mouth of that branch of the Oder, which is called the Swine.

The country round Stettin is delightful, and the lofty shore of one side of the Oder affords charming views. In the river, which now widens and now contracts its channel, are several islands both above and below the town, which increase the charms of the prospect. The population of Stettin is 26,000, and it publishes *two* Journals. East Long. 14° 45′ 45″. North Lat. 53° 25′ 36″.

STEUBEN, county of New York, bounded W. by Alleghany county in the same state; NW. by Livingston county; N. by Ontario; NE. by Yates county and Seneca Lake; E. by Tioga county of New York, and S. by Potter and Tioga counties, Pennsylvania. This county is very nearly a square of 40 miles each side; area 1600 square miles, extending in lat. from 42° to 42° 34′ N. and in long. from 0° 2′ E. to 0° 48′ W. from Washington City.

The surface of this county if not mountainous is very hilly and rocky, but possessing much excellent soil. Compared with the actually determined level of Tioga river below the eastern boundary of Steuben; the lowest part of the arable surface of that county must exceed 900 feet, and the far greater part rise above 1000 feet, relatively with the mean Atlantic tide. This elevation is equivalent to $2\frac{1}{2}$° of lat., Lake Ontario being but 231 feet above the ocean level; the higher valley of Tioga river, comprising the much greater part of Steuben, is about 800 feet, or nearly equivalent to 2° of lat. above the lake. This difference of relative height explains the true reason why a milder temperature is found along the lake border, than on any part of Steuben.

With the exception of the north-eastern part which slopes in that direction, and is drained into Seneca Lake, the body of the county is in the valley of Tioga, with a declivity to the south-eastward. As a physical section it constitutes the extreme north-western part of the basin of Susquehanna.

The Tioga or Chemung is formed by three branches: Tioga proper flowing westwardly from Tioga county, Pennsylvania; the middle branch, Canisted, having its most remote sources in Alleghany county; and the northern branch Conhoctor, rising in Livingston county. The Tioga and Canisted unite, and two or three miles below their junction receive the Conhoctor, near the Painted Post, in the south-eastern part of Steuben. It is remarkable, that though rising in so high and hilly a country, all these small rivers are navigable for down stream craft and rafts from near their sources.

The rapid and extensive settlement of this elevated and hilly county is shown by the list of Post-Offices, which amount to 49 according to the recent list now (April 1831) in the course of printing. Bath, the county seat on the left bank of the Conhocton, a little north-east of the centre of the county, is a fine thriving village, with a waving and pleasant site, N. lat. 42° 23′, long. 0° 21′ W. from, and by post road 299 miles a little W. of N. from W.C., and 216 miles NW. by W from Albany. By the census of 1820 this county contained 21,989 inhabitants.

STEUBENVILLE, post village and seat of justice, Jefferson county, Ohio, situated on the right bank of Ohio river, 40 miles SW. by W. from Pittsburgh, 82 NE. by E. from Zanesville, and 136 in a similar direction from Columbus; and by post roads 284 miles NW. by W. from W. C. It was laid out in a dense forest in 1798. The site is a bottom or plain rising by a gentle acclivity to the foot of the adjacent hills. The opposite bank on the Virginia side rises from the river margin in craggy precipices, which with high but rounded hills on its own margin gives to Steubenville the appearance of occupying the base of a deep valley, and such is the fact; the hills on both sides rise to upwards of four hundred feet above the level of the plain on which the town stands. The streets are elevated above high water, and the whole has a a romantic and pleasing effect on the eye. The dwelling houses amount to about 500, extending along streets laid out at right angles to each other in a northern and southern, and eastern and western direction, and very nearly parallel, or at right angles, to that part of Ohio river opposite the town. In 1820 the population amounted to 2539.

The public buildings are a court-house, two banks, several places of public worship, two large factories, one of woollen and the other of cotton. There are two weekly newspapers printed here, and an academy for education in operation. DERBY.

STEWART, MATTHEW, D.D. a celebrated Scottish Mathematician, was the son of the Rev. Dugald Stewart, minister of Rothsay, and was born in the year 1717. At the age of seventeen, he went to Glasgow, where he studied mathematics under Dr. Robert Simson, from whom he imbibed that love of the ancient geometry which characterized his future studies. As his views in life required his attendance at the college of Edinburgh, he went there in 1741, where he attended the lectures of Colin Maclaurin. Here he devoted himself to his favourite studies, and kept up a regular and intimate correspondence with Dr. Simson of Glasgow. In the midst of these pursuits, he was appointed to the living of Roseneath, where he completed his "General Theorems," a series of curious and interesting propositions which he published in 1746, and which, though given without any demonstrations, placed the author among the geometers of the first order.*

In the summer of 1746, the death of Mr. Maclaurin created a vacancy in the mathematical chair of the University of Edinburgh, and such was the superiority over the other candidates which the General Theorems gave to Mr. Stewart, that he was elected to the office in September 1747.

In the 2d volume of the Essays of the Philosophical Society of Edinburgh, Mr. Stewart published a very neat solution of Kepler's Problem. In 1761 appeared his *Tracts Physical and Mathematical*, which relate to the doctrine of centripetal powers, to the theory of the lunar motions, and to the determination of the sun's distance from the earth. In 1763 he brought out his *Propositiones Geometricæ more veterum demonstratæ*, and in the same year he published his *Essay on the Sun's Distance from the Earth*. In this tract he made the sun's parallax only 6″.9, and consequently his distance so much as 29,875 semi-diameters of the earth, or 118,541,428 English miles. This result was received with surprise, and brought forth two answers to the tract, the one by Mr. Dawson of Sudbury, and the other by Mr. Landen, who pointed out certain errors which had been committed by Mr. Stewart. To these animadversions Mr. Stewart made no reply. His health had now begun to decline, and with the view of restoring it he made a tour through England, and paid a visit to Earl Stanhope, from whom he received singular marks of attention. In 1772, when his son, Mr. Dugald Stewart, was able to lecture for him, he retired to the country, where he spent the greater part of his life. In 1775 he resigned his chair, and his son was elected joint professor with him. His health continued to decline, and he died on the 23d January 1785, at the age of 68.

STEWART, DUGALD, a celebrated metaphysical writer, was born at Edinburgh on the 22d November 1753, and was the only son who survived the age of infancy of the celebrated Dr. Matthew Stewart, professor of mathematics in the College of Edinburgh, and Miss Stewart, daughter of Mr. A. Stewart, writer to the signet. When a child, his health was feeble and precarious, and it was only by the greatest care that his parents succeeded in re-establishing it. At the age of seven he went to the High School, where his talents were favourably displayed, and after completing the usual routine of instruction at that academy, he was admitted a student in the University. Under the roof of his father, he was early initiated into geometry and algebra; but the peculiar bias of his mind was exhibited during his attendance on the lectures of Dr. Stevenson, then professor of logic, and of the celebrated Dr. Adam Ferguson, who filled with so much talent the chair of moral philosophy. It was this circumstance, no doubt, that induced his father to send him, at the age of eighteen, to the University of Glasgow, to attend the lectures of Dr. Reid, who was then sustaining, single-handed, the honour of that seat of learning, which had in the course of a few years been deprived of the services of Dr. Robert Simson, Dr. Adam Smith, and Dr. Black. In the session of 1771-1772, he attended a course of Dr. Reid's lectures, and was thus enabled to prosecute, under his great master, that important science which he was destined to illustrate and extend. The progress which he here made in his metaphysical studies was proportioned to the ardour with which he devoted himself to the subject; and, not content with listening merely to the instructions of his master, or with the speculations of his leisure hours, he composed during the session that admirable Essay on Dreaming, which he afterwards published in the first volume of his *Philosophy of the Human Mind*.

The health of his father had been for some time declining, and in the autumn of 1771 it had become so precarious, that Mr. Stewart was called upon to prepare for teaching the mathematical classes during the ensuing session. This duty, which devolved upon him at the age of nineteen, he discharged with great credit to himself, and, notwithstanding the high reputation of his father, the great success of his son brought an additional number of students to the class.

In the year 1774, when he had reached his twenty-first year, he was appointed assistant and successor to his father,—a situation which he continued to fill till the death of Dr. Stewart in 1785.

In the year 1778, when Dr. Adam Ferguson was appointed secretary to the commissioners for quieting the disorders which had broken out in America, Mr. Stewart undertook to supply his place during the session of that year; and this unexpected occupation was the more severe, as he had previously pledged

* The first demonstration of any considerable number of these was printed in the Edinburgh Transactions by the Rev. Dr. Small of Dundee. The demonstrations of others have been lately communicated to the Royal Society of Edinburgh, by Mr. Alexander Galloway, of the Royal Military College, Sandhurst.

himself to deliver a course of lectures on astronomy, in addition to the usual labours of his two mathematical courses. Three days after he had undertaken this difficult task, Mr. Stewart commenced his course of Ethics, and with no other preparation but that which he was able to make in the morning, he delivered a course of extempore lectures, which displayed in a remarkable degree the vigour of his mind, and the extent of his general information. Before the close of the session, his health had obviously suffered from the bodily as well as the mental fatigues to which he had been exposed, and such was the degree of his exhaustion, that it was necessary to lift him into the carriage when he set off for London at the close of the session.

The reputation of Mr. Stewart had now become so great, that several of the English and Scottish nobility were desirous of placing their sons under his superintendance; and he accordingly, in 1780, agreed to receive some pupils into his house. Among these were the late Marquis of Lothian, the late Lord Belhaven, Basil Lord Daer, the late Lord Powerscourt, Alexander Muir Mackenzie, Esq. of Delvin, and the late Mr. Henry Glassford. He accompanied the Marquis of Lothian to Paris in 1783, and on his return from the Continent, in the autumn of the same year, he married Miss Bannatine, daughter of Neil Bannatine, Esq. a merchant in Glasgow, by whom he had a son, the present Lieutenant-Colonel Matthew Stewart, who inherits no small share of the talents and acuteness of his father.

In consequence of the failure of Dr. Ferguson's health in 1784, he resolved upon giving up the duties of a public lecturer, and an arrangement was made, by which Mr. Stewart should receive the moral philosophy class, while Dr. Ferguson should be conjoined in the professorship of mathematics with Professor Playfair, and thus retain the larger salary which was attached to that chair. In 1787, Mr. Stewart was left a widower, and in the following summer he accompanied the late Mr. Ramsay of Barnton on a visit to the Continent.

In the year 1790 he married Miss Cranstoun (the youngest daughter of the Honourable George Cranstoun), a lady of congenial sentiment and talent, who contributed greatly to the happiness of his future years. In the tranquillity of domestic life, so favourable to the pursuits of science, Mr. Stewart seems to have begun with earnestness to prepare for the press the first of that series of works by which he has been so highly distinguished. In 1792 he published the first volume of his *Elements of the Philosophy of the Human Mind*. In this work he has stripped the science of the Human Mind of much of that mystery and paradox in which it had been involved; and while he has treated its most important and difficult topics with all the depth and clearness of mathematical talent, he has, at the same time, enriched his speculations with the stores of his varied learning, and adorned them with all the elegancies of his classical taste. This volume contains a review of the intellectual powers of man. On many important points, Mr. Stewart's views necessarily coincided with those of his illustrious master; but while he treated the opinions of Dr. Reid with all the veneration of a disciple, he never scrupled to examine them with the freedom of an equal, and to advocate opposite opinions, or strike into a new train of thought, into which he had been led by a more profound or a more ingenious investigation. In this, as well as the other two volumes of his work, Mr. Stewart's great aim was to vindicate the principles of human knowledge against the attacks of modern sceptics, and to lay a solid foundation for a rational system of logic.

The first volume of Mr. Stewart's work did not excite that notice to which its own merit and the high reputation of its author unquestionably entitled it. The philosophy of the mind was then a subject of comparatively little interest, and though divested of its usual repulsive aspect, it was not considered, as it is now, a necessary branch of a polite education. The long interval of twenty-one years, which elapsed between the publication of the first and the second volume, and the publication of his volume of Philosophical Essays at an intermediate period, may afford us some reason for believing that Mr. Stewart had abandoned the prosecution of his plan.

The continuity of his studies was, indeed, interrupted by a series of biographical works, which almost necessarily devolved upon him. The first of these was *An Account of the Life and Writings of Dr. Adam Smith*, the celebrated author of the *Wealth of Nations*. This memoir, which occupies 82 quarto pages, was read before the *Royal Society of Edinburgh* on the 28th January and the 18th March 1793, and is published in the third volume of their Transactions. It forms one of the finest examples of biographical composition, and, independent of the value which it derives from its luminous exposition of the principles of Dr. Smith's philosophy, it is rendered interesting by the numerous anecdotes which it contains of the great men which had a short time before adorned the literary history of Scotland.

At the request, we believe, of Dr. Robertson himself, made a short time before his death, Mr. Stewart undertook to draw up an account of the life and writings of that illustrious historian. It was read before the Royal Society of Edinburgh in March 1796, and was afterwards published in a separate volume in 1801. To the memory of Dr. Reid, Mr. Stewart felt it his duty to pay the like homage, and he accordingly completed, in 1802, his account of the life and writings of that eminent metaphysician.

In the year 1796, Mr. Stewart was again induced to receive a few pupils into his house, and at this time the present Earl of Dudley, the Earl of Warwick, the late Lord Ashburton, the son of Mr. Dunning, Lord Palmerston, his brother the Honourable Mr. Temple, and Mr. Sullivan, the present Under Secretary of War, were placed under his care. The Marquis of Lansdown, though not under Mr. Stewart's superintendance, was at this time studying in Edinburgh, and was honoured with Mr. Stewart's particular regard. Their friendship continued unabated, and Mr. Stewart had the happiness of seeing the Marquis of Lansdown, Lord Dudley, and Lord Palmerston, members of the same cabinet. Mr. Brougham and Mr. Horner were at the same time two of the public pupils of Mr Stewart.

Mr. Stewart had been long desirous to deliver a course of lectures on Political Economy, but it was generally understood that he was deterred from carrying this design into effect by the peculiar character of the times in which he lived. In 1800, however, when the effervescence of political speculation had subsided, he gave a course of lectures on Political Economy, but we believe they were not repeated more than once in subsequent sessions.

In 1806, when an accidental circumstance led the English and the French governments into an amicable correspondence, the Earl of Lauderdale was sent to Paris to adjust the preliminaries of a general peace. This nobleman requested Mr. Stewart to accompany him as a friend, and they accordingly spent some time in the French metropolis. Here Mr. Stewart had an opportunity of seeing many of the eminent individuals with whom he had formed an acquaintance previous to the Revolution, and of being introduced to some of the great men who then adorned the science and literature of France.

While individuals of inferior talent, and of much inferior claims, had received the most substantial rewards for their services, it had long been felt that a philosopher like Mr. Stewart, who derived so small an income from his professional occupations, should have been so long overlooked by his country. It fell, therefore, to be the especial duty of the administration of Mr. Fox and Lord Grenville, to correct the oversight of their predecessors. They created for Mr. Stewart the office of Gazette Writer for Scotland, a situation which, as it could be performed by deputy, required no personal labour, and which added largely to his income. The creation, or rather the revival of this office, excited a considerable difference of sentiment. It was agreed on all hands, that the distinguished individual on whom it was conferred, merited the highest recompense; but it was felt by the independent men of all parties, that a liberal pension from the crown would have expressed in a more elegant manner the national gratitude; and would have placed Mr. Stewart's name more conspicuously in the list of those public servants, who are repaid in the evening of life for the devotion of their early days to the honour and interest of their country.

In the year 1808, Mr. Stewart sustained a severe domestic calamity in the loss of his second and youngest son, who was cut off by consumption in the 18th year of his age, while pursuing his academical studies. To divert his thoughts from this deep affliction, Mr. Stewart devoted himself to the composition of his *Philosophical Essays*, a work which appeared in 1810, went through three editions, and added greatly to his reputation. As the first part of this work is a commentary on some elementary and fundamental questions which divided the opinions of philosophers in the eighteenth century, Mr. Stewart regarded it as so far a continuation of his great plan, that he recommends his younger readers to peruse it after they have completed the first volume of his *Philosophy of the Human Mind*. About a year after the death of his son, Mr. Stewart resigned the Moral Philosophy Chair, and was re-appointed joint professor along with Dr. Thomas Brown. By this arrangement, which his appointment from Government allowed him to effect, he was enabled to retire from the duties of active life, and to pursue in retirement those philosophical inquiries, of which he had yet published but a small part. He therefore quitted Edinburgh, and removed with his family to Kinneil House, near Borrostownness, a seat of the Duke of Hamilton, and about twenty miles from Edinburgh.

Although it was on Mr. Stewart's recommendation that Dr. Brown was raised to the Chair of Moral Philosophy, yet the appointment did not prove to him a source of unmixed satisfaction. The fine poetical imagination of Dr. Brown, the quickness of his apprehension, and the acuteness and ingenuity of his argument, were qualities but little suited to that patient and continuous research which the phenomena of the mind so peculiarly demand. He accordingly composed his lectures with the same rapidity that he would have done a poem, and chiefly from the resources of his own highly gifted but excited mind. Difficulties which had appalled the stoutest intellects, yielded to his bold analysis, and, despising the patient formalities of a siege, he entered the temple of pneumatology by storm. When Mr. Stewart was apprised that his own favourite and best founded opinions were controverted from the very chair which he had scarcely quitted; that the doctrines of his revered friend and master (Dr. Reid) were assailed with severe and not very respectful animadversions; and that views even of a doubtful tendency were freely expounded by his ingenious colleague, his feelings were stongly roused; and though they were long suppressed by the peculiar circumstances of his situation, yet he has given them full expression in a very interesting note in the third volume of his Elements, which is alike remarkable for the severity and delicacy of its reproof. Upon the death of Dr. Brown, on the 2d of April 1820, Mr. Stewart resigned the Chair of Moral Philosophy, and was succeeded by Professor Wilson, a man of varied and powerful intellect, admired as a poet, and distinguished as an orator.

In October 1810, our eminent countryman, Mr. James Wardrop, communicated to Mr. Stewart an account of a very remarkable youth, James Mitchell, who was born both blind and deaf, and who consequently derived all his knowledge of external objects from the senses of touch, taste, and smell. Mr. Stewart was delighted with the prospect which this case afforded of establishing the distinction between the original and the acquired perceptions of sight. This expectation was not realized; but Mr. Stewart collected all the facts regarding the remarkable youth, and embodied them in a highly interesting memoir, which was read before the Royal Society of Edinburgh in the beginning of 1812. It is entitled "*Some account of a Boy born Blind and Deaf, collected from authentic sources of information, with a few remarks and comments;*" and was published in the seventh volume of the *Transactions of the Royal Society of Edinburgh.* In consequence of the interest which was excited by this communication, Mr. Stewart was anxious that Mitchell should be brought to Edinburgh, and educated under the superintendance of persons capable of studying the development of his mental powers. He accordingly submitted this idea to the council of the Royal Society, who entered eagerly into the plan, and resolved to apply to Government for a small pension to enable Miss Mitchell and her brother to reside near Edinburgh. Lord Webb Seymour, one of the Vice-Presidents of the Society, transmitted the wishes of the council to the Earl of Liverpool, then first Lord of the Treasury. The Prime Minister of Great

Britain not only refused to science and humanity the small pittance which was craved, but ventured to strengthen the ground of his refusal, by expressing a doubt whether the object which the Society had in view was likely to add to the comfort of the unfortunate object of their patronage. The writer of these lines was one of the five members of council to whom this answer was read, and he will never forget the impression which it made upon the meeting—the suppressed feeling of mortification and shame which was visible on every countenance. The guardian of the British treasury was entitled to refuse the application which had been made to him, but he had no right to question the humanity by which that application was dictated. The character of Mr. Dugald Stewart should have been a sufficient guarantee that the personal comfort and happiness of Mitchell would be the first objects of his solicitude.

In the year 1813, Mr. Stewart published the second volume of his *Elements of the Philosophy of the Human Mind.* This volume relates entirely to *Reason* or *the Understanding, properly so called*, and as the author himself observes, the subjects of which it treats are of necessity peculiarly dry and abstruse; but he regarded them as so important, that he laboured the whole of the materials which compose it with the greatest care and diligence. In the fourth chapter he treats more particularly of the method of inquiry pointed out in the *Novum Organum* of Bacon, and he has directed the attention of his readers chiefly to such questions as are connected with the theory of our intellectual faculties, and the primary sources of experimental knowledge in the laws of the human frame.

In the month of January 1822, Mr. Stewart experienced a stroke of palsy, which considerably impaired his powers of speech, and unfitted him in a great degree for the enjoyment of general society. Unable to take regular exercise, or to use his right hand, he was reduced to a state of great dependence on those round him. The faculties of his mind, however, were in no respect impaired by this severe attack, and with the assistance of his only daughter, who acted as his amanuensis, and who understood his imperfect articulation, he was enabled to prepare his works for publication with an ardour of mind and a freshness of intellect which formed a striking contrast with his bodily weakness.

Although the progress of his great work was interrupted by his Dissertation on the progress of Metaphysical and Ethical Philosophy, which he composed for the *Supplement to the Encyclopedia Britannica*, yet he was able to complete the third volume of his *Philosophy of the Human Mind* in 1827. This volume contains a continuation of the second part, viz. two chapters, one on *Language*, and the other on *the Principles or Law of Sympathetic Imitation;* and also the third part, which consists of two chapters, one *on the Varieties of Intellectual Character*, and the other *a Comparison between the Faculties of Man and those of the Lower Animals.* To this last chapter he has added as an appendix, his account of James Mitchell, with a supplement containing a recent account of the manners and habits of this interesting individual.

In 1827 and 1828, Mr. Stewart was occupied with the fourth volume of his *Philosophy of the Human Mind*, containing his Inquiries into the Active and Moral Powers of Man, and he was fortunately able to complete it a few weeks before his death, and thus to bring to a close that great work, on which he had spent the flower of his youth, and the maturity of his more advanced years.

Mr. Stewart's health had been for some time declining, but when he was on a visit to Edinburgh in the month of April 1828, he experienced a fresh paralytic attack which carried him off on the 11th of June, in the 75th year of his age. His remains, which were accompanied to the grave by the magistrates of the city, and the professors of the university, were interred in the family burying-ground in the Canongate church-yard, already honoured as the burial place of Adam Smith. Mr. Stewart's personal friends and admirers have contributed a large sum, with which a monument will be speedily erected to his memory on some conspicuous spot in our northern metropolis.

Mr. Stewart left behind him a widow and two children, a son and daughter, whom he loved with the tenderest affection. To Mrs. Stewart and his only daughter he owed that sunshine of happiness, which, but with one cloud, Providence shed over his domestic life. They had been the ornaments of his social circle when his public station required him to mix largely with the world; and when they were called to higher duties by the infirmities of his age, they discharged the obligations of conjugal and filial love with that self-devotion and sustained tenderness, which have their residence only in the female heart. His only son, Lieutenant-Colonel Matthew Stewart, already known by an able pamphlet on Indian affairs, and who, we believe, is now occupied in a larger work on the same subject, was fortunately in Scotland at the time of Mr. Stewart's death, and was able to pay the last duties of affection to his venerable parent.

Mr. Stewart was about the middle size, and was particularly distinguished by an expression of benevolence and intelligence, which Sir Henry Raeburn has well preserved in his portrait of him, painted for the late Lord Woodhouselee before he had reached his 55th year.* Mr. Stewart had the remarkable peculiarity of vision which made him insensible to the less refrangible colours of the spectrum.† This affection of the eye was long unknown both to himself and his friends, and was discovered from the accidental circumstance of one of his family directing his attention to the beauty of the fruit of the Siberian crab, when he found himself unable to distinguish the scarlet fruit from the green leaves of the tree.

Mr. Stewart's name honoured the lists of various learned academies. He was one of the members of the Philosophical Society of Edinburgh at its incorporation with the Royal Society in 1783. He was a fellow of the Royal Society of London, an honorary member of the Imperial Academy of Sciences at St. Petersburgh, a member of the Royal Academies of Berlin and Naples, of the American Philosophical

* At a much later period Sir Henry painted another portrait of Mr. Stewart, and Mr. Wilkie still more recently executed a striking likeness of him in black lead. Mr. Joseph has also completed a bust of Mr. Stewart with his usual talent.

† See *The Edinburgh Journal of Science*, No. xix. p. 153.

Societies of Philadelphia and Boston, and honorary member of the Philosophical Society of Cambridge.

Besides the works which we have mentioned in the course of this notice, Mr. Stewart published his *Outlines of Moral Philosophy*, which appeared in 1793, and which he used as a text-book. This work has been recently translated into French; and it has been used as a text-book in several Colleges in America. He was also the author of two eloquent pamphlets on a local controversy now sunk into oblivion. He had laid down the resolution of never publishing any thing anonymously; and we believe he never deviated from so excellent a rule. See Dr. Brewster's *Journal of Science*, No. xx. p. 194, for a fuller account of the philosophy and private character of Mr. Stewart.

STEWART, county of Tennessee, bounded by Montgomery county, Tennessee, NE; Dickson SE; Humphries S; Tennessee river separating it from Henry county, Tennessee, W; and Callaway county, Kentucky, NW; and by Trigg county, Kentucky, N. Length diagonally from SE. to NW. 40; mean breadth 20; and area 800 square miles. Extending in lat. from 36° 14′ to 36° 37′ N.; and in long. from 10° 43′ to 11° 12′ W. from W. C. This county is bounded SW. and W. by Tennessee river, and traversed by Cumberland river, both streams flowing to the northwestward, at a distance apart of from 23 to 8 miles, inclining towards each other as they leave Tennessee and enter Kentucky. The surface moderately hilly, and soil productive. Dover, on the left bank of Cumberland river, is the county town. It is situated about 75 miles by the landroad NW. by W. from Nashville, at N. lat. 36° 28′, and long. 10° 49′ W. from W. C. Beside Dover there are post-offices in this county at Brunsoris, Dover Furnace, Green Tree Grove, Hamlet's and Trougdale. In 1820 Stewart contained a population of 8388.

STEWARTSTOWN, township and post village, Coos county, New Hampshire, situated on Connecticut river, opposite the mouth of Hall's river, by post-road 164 miles N. from Concord. N. lat. 44° 56′, long. 5° 31′ E. from W. C.

STEWARTSVILLE, post-village in the western part of Westmoreland county, Pennsylvania, on the main road from Greensburg to Pittsburg; 13 miles NW. by W. from the former, and 19 SE. from the latter, and by post-road 204 miles NW. by W. from W. C.

STIRIA. See STYRIA.

STIRLING, an ancient town of Scotland, and capital of the county of Stirling, is situated in a plain watered by the Forth, and on the sloping ridge of a rock, on the western and precipitous extremity of which stands Stirling castle. The town is irregular, the street on the crest of the hill is broad, but the other streets are narrow; several new streets containing elegant modern buildings have been erected on the north side of the town. At the south side of the town, several elegant villas extend along each side of the road, and a little farther south is Wellington Place, where several handsome houses have been built.

The principal public buildings are two churches, three hospitals, the town house, the jail, the school house, a public library and reading room, a military hospital and the castle. The east church, erected in 1494, is a fine building, which received some additions from Cardinal Beaton; the west church, said to have been built also in 1494, and to have constituted one building with the east church, is in the rude Gothic style, and has been lately repaired after a plan by Mr. Gillespie; it is now internally one of the most commodious and handsome churches in Scotland. The oldest of the three hospitals, built in 1530, for the support of poor tradesmen, was endowed by Robert Spittal, tailor to James IV.; the second, for twelve decayed guild brethren, was founded in 1639 by John Cowan. It is furnished with a steeple and bell and apartments for the guildry. Its annual revenue is about £3000. The third, for maintaining and educating the children of decayed tradesmen, has a revenue of nearly £500, and was founded by John Allan. The town house is a spacious building, with convenient apartments for the town courts. The jail, which has been recently built on an approved plan, contains an elegant hall for the sheriff and circuit courts. The grammar school, the academy for arithmetic and mathematics, and the English school, are commodious and good buildings. The public library and reading room is a new and elegant building, having a spire 120 feet high. The library contains several thousand volumes. The military hospital occupies Argyll's Lodging, built in 1633, and in which John Duke of Argyll lived in 1715.

The castle is situated at the precipitous extremity of the ridge on which the town stands. It is of very ancient date, and still exhibits marks of royal magnificence. James II. was born here, and the room called Douglas's room is still shown where that cruel monarch stabbed with his own hand his kinsman William Earl of Douglas. A skeleton supposed to be that of the earl was some years ago found in the cleft of the rock directly beneath the window of this room. The hall for the meetings of parliament, built by James III. is now used as a barrack. The chapel royal, built by James VII. for the baptism of Prince Henry, adjoins to the barracks, and is now a storeroom and armoury. The palace is a large building of a square form, enclosing a quadrangular court. A number of grotesque figures on pedestals adorn its exterior. It now forms barrack-wards to the garrison, a house to the governor, and apartments for the inferior officers. The apartments occupied by George Buchanan while tutor to James VI. are still shown. In one of the apartments of this quadrangle, called the king's room, the roof was covered with rich carvings in oak, which have been engraved and described in a work published in 1817, called *Lacunar Strevelinense.* Queen Anne's battery, with bombproof barracks, was erected at the beginning of the last century on the south side of the castle; the rampart is mounted with about 36 guns. On the south side of the castle is a piece of flat enclosed ground which was devoted to tournaments; and a rock whence the ladies observed them is called the Ladies' Rock. No fewer than *twelve* fields of battle are seen from the castle, the prospect from which is universally admired. Towards the east, Edinburgh and the windings of the Forth form one of the most interesting portions of it. The castle rock is basaltic. Around it is an agreeable walk, in many places cut from the solid rock.

Stirling enjoys a considerable inland trade, besides a small trade with the Baltic; vessels of about 70 tons can come up to the quay. Cotton and woollen goods, but particularly carpets, are among its chief manufactures; it has two banks and two weekly papers; it is governed by a provost, four bailies, a dean of guild, treasurer, and fourteen other counsellors; it sends a member to parliament along with Dunfermline, Inverkeithing, Queensferry and Culross. The revenue of the town from the salmon fishing amounts to £2250 per annum. The population of the burgh and parish in 1821 was

STIRLINGSHIRE, a central county of Scotland, bounded on the north by Perthshire and Clackmannanshire; on the east by the Firth of Forth and Linlithgowshire; on the south by Lanarkshire; and on the south-west and west by Dumbartonshire; is about 36 miles in length, and from 12 to 17 in breadth; and contains an extent of about 645 square miles, or 412,800 English acres. The ecclesiastical divisions are, twenty-one parishes, besides portions of other four, parts of which are in the adjacent counties. This county contains one royal borough, viz. Stirling, which is the county town, and two large towns Falkirk and St. Ninians, besides several large and flourishing villages.

The appearance of many parts of Stirlingshire is mountainous to a considerable degree, particularly in the vicinity of Loch Lomond on the north, and in the parishes of Denny, Kilsyth, Kilpatrick, Campsie, and Baldernock on the south. Some parts of the central district are also very hilly. The principal ranges of hills are those of Lennox, Campsie, and Kilpatrick in the southern district. The Lennox hills extend from Dumbartonshire to the vicinity of the town of Stirling, and seldom exceed an elevation of 1500 feet above the level of the sea. The height of the Campsie hills is about 1500, and that of the Kilsyth hills 1368. From the highest of the last mentioned range of hills, there is one of the finest views in Scotland, which has been computed to embrace an extent of more than 12,000 square miles. The highest mountain in the county is Benlomond, in the north, which is 3262 feet high; the next highest is Bencloch in the parish of Alva, which attains the height of 2400 feet. Many of these hills, especially in the southern district, partake more of the lowland than the highland appearance, as their summits, and many parts of their sides, are covered with green sward, which affords excellent pasturage for sheep.

On the north, and especially on the east of the Lennox hills, the elevation of the country above the level of the sea is so low as 162 feet. This district is very rich and fertile, producing excellent crops of grain. The western and southern parts of the county, which are very hilly, for the most part consist of moss, and tracts of heath, and green pastures, interspersed with arable land, which is chiefly confined to the banks of the rivers.

Almost every variety of soil to be met with in Scotland occurs in Stirlingshire; but the most common is the alluvial or coarse land, which occupies an extent of about 40,000 acres on the banks of the Forth, which is the most fertile part of the county. In this soil there are beds of shells, clay, marle and moss. Small patches of rich loam occur in many parts of the county. The soil on the banks of the rivers, in the western and central districts, is chiefly of a light and gravelly description.

Stirlingshire is inferior to few districts of Scotland, in the quantity and variety of its mineral productions; the most abundant of which are coal, ironstone, limestone, and sandstone. The principal coal pits are situated in the southern base of the Lennox hills, and extend from Baldernock on the west, to Denny and St. Ninians on the east. Coal is also found in the eastern district, in the vicinity of the Forth and Clyde Canal. Stirlingshire yields this mineral in such abundance, as not only to be sufficient for home consumption, but, by means of the Union Canal, to supply the inhabitants of the metropolis at a much cheaper rate than they were formerly accustomed to pay. The ironstone, limestone, and sandstone is found in the same district with the coal, one stratum of limestone being often found above, and another below a stratum of coal. Veins of silver were discovered, and wrought about sixty years ago, but the working of them was soon discontinued. Copper, lead, and cobalt, have also been raised at different periods, but not in any considerable quantities.

The Forth is the principal river in Stirlingshire, and though not the largest, has always held the first rank among the rivers of Scotland. It has its origin in a spring near the summit of Benlomond, and after running eight or ten miles under the name of the water of Duchray, and flowing through part of Perthshire, where it is called Avendow, or the Black River, it again enters Stirlingshire, under the denomination of the Forth, and after receiving the Teith, Bannockburn, Ardoch, and Allan, it enters the Carse of Stirling, about six miles to the west of that town; a few miles further on it becomes navigable for vessels of 70 tons. Below Stirling the sinuosity of this river is very remarkable; the distance from the above town to Alloa, which is only seven miles in a direct line, is more than twenty by the course of the river, owing to its numerous windings, which are called the Links of the Forth. A little below Alloa it is joined by the Devon from the north-east, and shortly after expands into that noble estuary called the Frith of Forth, and leaves Stirlingshire a little to the south of Grangemouth. The Carron, which is the next river in size to the Forth, rises in the central district, and after flowing on in an easterly direction, joins the Forth at Grangemouth. This river is navigable for vessels of

200 tons, for about two miles from where it joins the Forth. The smaller rivers are the Bannockburn, celebrated for having been the scene of the battle between the English and the Scotch armies, in which the latter, under Bruce, completely routed the English, and established the independence of Scotland (See BANNOCKBURN), the Avon, the Enrick, the Blane, and the Kelvin, none of which are worthy of particular notice.

The manufactures of Stirlingshire are various. At Stirling there are manufactories of carpets, coarse cloths, and cottons. There are several large establishments for cotton, paper, copperas, alum, Prussian blue, soda, &c. near Campsie. There are many large distilleries in different parts of the county, in which an immense quantity of spirits is made. But the principal manufactory in the shire is one for iron-ware of every description, on the banks of the Carron, which is celebrated over all Europe, and which we have already fully described under our article CARRON WORKS.

The agriculture of Stirlingshire is subject to considerable variation, owing to the great variety of soil and situation. The carse lands which are arable are portioned out into small farms, of from 15 to 100 acres, which sometimes afford a rent of £4 an acre. But the hill farms sometimes extend to near 1000 acres. Large crops of wheat, barley, beans, pease, turnips, potatoes, &c. are raised: the use of artificial grasses has also been very generally adopted in this county. The extensive ranges of moorland, in the upland districts, are exclusively devoted to the feeding of numerous flocks of sheep. There are few cattle reared in Stirlingshire, as the county is very generally supplied by the Highland drovers. The sheep are of the blackfaced or Highland breed.

Stirlingshire, which had in 1828, 129 freeholders, sends one representative to parliament; and the town of Stirling, in conjunction with Culross, Dunfermline, Inverkeithing and Queensferry, elects another.

In this county there are several highly interesting relics of antiquity. There are still some remains of the Roman Wall, called the Wall of Antoninus, which intersected the county. At the scene of the battle of Bannockburn a stone is exhibited, in which the royal standard was pitched. In the eastern part of the county several other battles were fought between the English and Scots.

The population of Stirlingshire was 65,376 in 1821; of which 31,718 were males, and 33,658 females. The number of families employed in agriculture were 2600; and those employed in trade and manufactures, 6641; and of those in neither of the above classes, 4492. See our articles ANTONINUS'S WALL, BANNOCKBURN, CARRON WORKS, FORTH, and SCOTLAND.

STOCKBRIDGE, post village in the western part of Berkshire county, Massachusetts, situated on the Housatonick river, 12 miles S. of Pittsfield, and by post road, 127 miles W. from Boston.] DARBY.

STOCKHOLM, the metropolis of Sweden, is situated on the northern and southern shore of the lake Maelar, and embraces likewise a number of islands lying between them. The greatest part of the town stands on the continent, the part which occupies the southern shore being called Sodermalm, and that on the northern Nordermalm, these being called the suburbs of Stockholm. The city, properly so called, occupies the largest island. It is the busiest part of the town, being in reality a sea-port, having handsome quays, bordered by stately ranges of buildings, where the principal merchants reside. The houses are, however high, the streets narrow, and the general aspect of it gloomy; but it contains what was called the new palace, the great church, or that of St. Nicholas, the bank, the corn-market, the spacious custom-house, and a great number of other elegant buildings. The palace occupies a great part of this island, and towering above all the other buildings of the city, it is visible on all sides, and commands a view of every part of Stockholm. The city is connected by means of a fine granite bridge with the Nordermalm or Norr-malm. This bridge leads at once into the great square, the stately magnificence of which, according to Dr. Clarke, is very imposing, and affords a concentration of almost every thing worth seeing in Stockholm. One entire side of it is adorned with the royal palace, another is occupied with the opera-house, containing the inscription *Musis Suecicis Gustavus* III. and in which that monarch was assassinated. Opposite to the opera-house is the palace of the princess royal, and in the centre of this area, opposite to the granite bridge, is a gigantic equestrian statue of Gustavus Adolphus in armour, facing the royal residence, and having an air of great grandeur. It is of gilt bronze, and stands on a pedestal of finely polished porphyry. The principal street here is Queen's Street, stretching in a straight line for more than a mile from the observatory to the side of the lake. The streets are here at right angles to each other, but several of them are narrow. From the great square a street conducts to a quay, near which stands the Stepholm church. Between the square, the quay, and that of the city, is the port of Stockholm, where all the vessels lie.

The Nordermalm contains likewise the ancient arsenal, now a theatre, the royal gardens, the surveyor's office, the great orphan-house, the free-mason's orphan house, the workhouse on the Sabbath Mountain, the church of St. Clare, the steeple of which commands a fine view, and which has a fine altar-piece, the churches of St. James and Adolphus Frederic, the observatory, the exhibition of models, the institution for widows, the lying-in hospital, and Drotning-house.

The city is connected by a bridge with the Ritterholm towards the west. The Ritterholm contains a spacious square, near which is the church of Ribterholm, a good looking building, and the burial place of the royal family. Here also stands the senate house, and the town house, the last of which contains two halls, one for the citizens, and the other for the peasants at the diets. The old palace, with the regalia, and the chamber of models, and the academy of arts, are also situated in this island. Between the city, the Nordermalm and the Ritterholm is the island of the Holy Ghost, which contains the king's stables, an extensive and splendid building. In the city and the Ritterholm, are the great Swedish school, a synagogue, a German, a

Finlandish, and a French church;—the academy of sciences, with its library and other collections, the mint, and the college of mines, with its fine cabinet of natural history.

The other islands are Admiralty-holm, consisting of naked romantic rocks, and containing the naval arsenal;—Castleholm, containing little more than a small palace on a naked rock;—Beckholm, Langholm, and Rackningsholm, all three of little importance; and Congsholm, part of which is built upon, and the rest occupied with gardens and desert rocks, and containing a church, the glass house, and the royal hospital;—Ladugards-land, containing the Hummel Garden; also Frederickshof, with the arsenal, and a collection of artificial curiosities, the artillery house, the laboratory and the docks; Little Hessinger and Beckholm.

The last portion of Stockholm is Sodermalm, situated to the south of the city. It contains a number of good stone buildings, which gradually fall off into a village bounded with gardens, and an uncultivated country. In the Sodermalm is situated the town house (an object worth visiting), the courts, the senate house, the Greek and Roman Catholic chapels, the churches of St. Mary and St. Catharine, with the schools and work-houses, the hospital, the mad-house, and the house of correction.

The number of bridges in Stockholm amounts to twelve. The houses are founded generally on piles. In the city they are built of stone, and are four or five stories high, but a great portion of the city is composed of mean buildings, constructed of wood, and even of miserable huts, inhabited by the most indigent persons. From this cause, Stockholm is, according to Kuttner, like no other city. After leaving the principal parts of the town, " you arrive," says Kuttner, " at immense naked rocks of granite, between which you meet with gardens, windmills, tobacco plantations, and wretched huts, all of which belong to the town, and are situated within the enclosure by which it is surrounded. In those parts of the town I have met with situations in which I imagined myself among the Alps, where I saw nothing but a few miserable huts scattered among the wildest and most romantic rocks, which conceal the other part of the city so completely, that you imagine yourself in an uninhabited country. If, however, you ascend to the summit of one of these rocks, you enjoy the most romantic, and at the same time the most magnificent views of a splendid metropolis; in a word, you survey with one look, palaces, churches, islands, lakes, harbours crowded with vessels, intermingled with naked rocks. This it is that renders Stockholm perhaps *unique* in its way. I never beheld from one point of view, any thing so beautiful, so magnificent, and so sublime, nor yet any thing so mean, so rude, and so wild, within the circumference of a metropolis."

The principal public building in Stockholm is the royal palace, a large quadrangular structure, with a court in the middle. It is said to be surpassed only by that of Versailles. The lower part of the wall is of polished granite. The upper part is of brick, covered with stucco, and the roof is of copper. It contains, besides the royal apartments, a neat chapel, the hall of the states, a gallery of paintings, the museum, and the King's library. The museum is a collection of antiques, made by Gustavus III. Among the statues is the celebrated Endymion, found in the villa Adriana; it is a figure somewhat larger than life, lying asleep, and quite naked. The royal library comprehended in 1821 above 40,000 volumes, and, among other curiosities, contains the copy of the (Vulgate) Bible, used by Luther, with manuscript notes in his own hand: and also the Latin Prayer Book of the emperor Ferdinand, which in the 30 years' war fell into the hands of Gustavus II.

In Lofin, otherwise called Drotningholm, or the Queen's island, stands the most magnificent palace belonging to the kings of Sweden, exhibiting the elegance, the taste, the luxury, and the magnificence of Versailles. The cabinet of natural history, adjoining the king's private library, is remarkable as having been arranged and described by Linnæus. Among the objects of interest in the capital, is the Fredericshof, or collection of artificial curiosities and armour, otherwise called the arsenal. The clothes and arms of Charles XII. and those of Gustavus III. are carefully preserved in this collection, which contains an immense number of standards and trophies taken chiefly from the Imperialists, Poles, Russians and Danes. Here also is the stuffed skin of the horse which carried Gustavus Adolphus at the battle of Lutzen, and the boat made by Peter the Great, at Sardam in Holland, which was taken by a Swedish vessel as it was conveying by sea to St. Petersburg.

The principal societies and institutions in this Metropolis are, 1st, The Academy of sciences, founded in 1739, divided into nine classes, and comprehending 100 native and 260 foreign members. 2d, The Swedish academy, founded in 1716, consisting of 18 members, whose object is,* the improvement of the Swedish language, poetry, and eloquence. 3d, The academy of painters and statuaries, founded in 1735. 4th, A military academy, established in 1796. 5th, An academy for painting and sculpture. 6th, An academy of music, established in 1761. 8th, A statistical agricultural society, established in 1772. 9th, A medical college. 10th, A saving bank, in which 5000 workmen have deposited money.

The harbour of Stockholm is particularly commodious. It can accommodate with safety a thousand sail of shipping, and the largest can come close to the quay. The entrance, however, to the harbour, is rendered dangerous by the numerous rocks and small islands with which it is beset; the distance of the harbour from the Baltic is more than twenty miles, and in one place the passage is contracted and bounded by high rocks. There is here a regular institution called the company of divers, which is bound to have persons ready to assist at all shipwrecks on the Swedish coast; they are entitled to a proportion of the goods saved as salvage. The number of vessels that enter the harbour annually is from

* It is a curious fact that this society awarded the gold medal to Gustavus III. for the best biographical Essay on Leonard Forstensohn, without knowing who was the author.

900 to 1100, and the trade of Stockholm is equal to two-thirds of that of the whole kingdom. In 1816 Stockholm shipped

	Shippounds.
Iron, - - - - - -	257,950
Copper, - - - - - -	3,350
Lead, - - - - - -	600
Brimstone, Alum, and Vitriol,	4,520

The chief exports are the above articles, also pitch, tar and timber. The annual export of iron is about 400,000 shippounds. The imports are salt and colonial produce, wine, French and British manufactures. The vessels employed in this trade are chiefly Swedish. The inland trade of Stockholm is considerable, and is greatly facilitated by the lake Maelar, which stretches sixty miles into the interior, and by means of the lake Hielmar, which is crossed by an old stone bridge, and the canals of Arboga, it extends from Stroemsholm over the four provinces, and reaches the boundaries of Dalecarlia.

The manufactures of Stockholm are leather, silk, cotton, hats, stockings, earthenware, watches, clocks, and articles of gold and silver. There are here also iron-founderies, glass-works, sugar-refineries. The population of Stockholm has been reckoned as high as 92,000, but very recent accounts make it only 78,000.* The number of Journals published in Stockholm is estimated at thirty. E. Long. of the observatory. 18° 30′ 30″. North Lat. 59° 20′ 31″. For farther information respecting this capital, See Cox's *Travels in Poland, Russia, Sweden*, &c., vol. iv. p. 33; Kuttner's *Travels through Denmark and Sweden*, &c. in 1798 and 1799; Catteau's *Voyage en Allemagne et en Suede*, tom. ii. p. 267, Paris 1810. Dr. Clarke's *Travels*, vol. v. p. 152. Rordanz's *European Commerce*, p. 211. Schubert's *Travels in Sweden*, &c. in 1817, 1818 and 1820, in German.

STOCKING MANUFACTURE, See Chainwork, Vol. V. p. 597. chap. ii. where this subject is fully treated. See chapter on the *Manufacture of Hosiery*. See also England, Vol. VIII. p. 584.

STOCKPORT, a large market and borough town of England in Cheshire. It is situated on the river Mersy, principally on the top and sides of a hill, and the streets are very irregular and steep. The principal public buildings, &c. are the parish church of St. Mary, a large but decayed structure; a Calvinist chapel; a Roman Catholic chapel; various meeting-houses for Presbyterians, Methodists and Quakers; a free school, founded in 1487; a large Dispensary built in 1797: a subscription school erected in 1805; and several Sunday schools, one of which, conducted by the Methodists, educates 3000 children gratuitously.

The cotton trade and the manufacture of silk form the principal employment of the population of this place. In 1810 there were twenty-five large factories for cotton goods, one silk mill, and several establishments for muslin; one of these factories is on a very extended scale, and is driven by the Mersy, which is brought to it by a subterraneous tunnel. Many of the London haberdashers have establishments here. By the canal lately made to Manchester, the trade of the town has been greatly facilitated. Stockport has two annual fairs. It is a place of great antiquity, the Romans having had a camp here, and the Saxons a fortress. The following was the population of the township in 1821.

Inhabited houses, - - -	3605
Number of Families, - -	4542

Males, - - - - -	10,495
Females, - - - - -	11,231
Total Population in 1821, -	21,726

STOCKTON upon Tees, a market and borough town of England in the county of Durham, is situated on the north bank of the Tees, which is crossed by a handsome bridge of five elliptical arches, that cost 8000*l.*, and was built between 1764 and 1771. The centre arch is 72 feet span and 23 high. It is neat and clean, and is reckoned the most handsome town in the north of England, both for the breadth of its principal street, and the general elegance of its buildings. This street, which is formed by the road to Durham and Sunderland, is about half a mile long, and sixty yards broad, with the market place in its centre, continuing nearly as broad to both ends. Several smaller streets branch off in different directions, and there is a spacious square at the north-east side of the town, which contains some good houses, and has been recently enclosed and planted by subscription. The houses are in general built of brick and covered with tiles, and the streets are well paved, flagged, and lighted. One of the principal public buildings is the church. It is a handsome brick building, with the doors and windows faced with stone; its length is 150 feet, and the tower eighty feet high. There is a theological subscription library kept in the vestry. There are also meeting-houses for Presbyterians, Roman Catholics, Quakers and Methodists. The town-hall, which stands in the middle of the principal street, is a large square structure, with a lofty cupola and spire. It is partly used for a tavern, and comprehends an elegant suite of assembly rooms, a court room, a coffee room, and other public apartments, with warehouses, shops, and a piazza underneath. In its vicinity in the market place is a handsome Doric column, thirty-three feet high. The custom-house is a commodious building. Stockton has a neat theatre and several libraries. The charitable institutions are a charity school for twenty boys and twenty girls, to which has been added a national school with about 350 children, a school of industry for girls, two Sunday schools, a dispensary, and almshouses for thirteen poor families. The almshouses occupy an elegant Gothic building, in which is a committee-room, where the affairs of the poor, and those of a savings bank are transacted.

Stockton, from its convenient situation, enjoys a

* See *Rev. Encyclopedique*, Mars. 1828, p. 598.

great trade, which has been much facilitated by a navigable cut made in 1810 for shortening the navigation of the river. The export trade consists of lead, hams, butter, pork, cheese, leather, grain, flour, sail-cloths, huckabucks, tammies, and plain linen. The imports, which are chiefly from the Baltic, Hamburg, Norway, and Holland, consist of hemp, flax, iron, timber, linen, yarn, sheetings, hides, bark, seeds, Geneva, &c. In 1795 the number of vessels belonging to the port was 47, carrying 5733 tons.

The principal manufactures of Stockton, are two of sail-cloth, two breweries, two rope-walks, two ship-yards, two iron founderies, a soap house, also manufactories for damask, diaper, and huckaback, towelling and check linens. There is also here a large dry dock.

The town is divided into two parts, one called the borough, and the other the town. The civil government is vested in a mayor, alderman, and recorder, besides inferior officers. Stockton had once a castle, but the moat is the only remaining vestige of it.

The population of the township in 1821 was

STODDARTSVILLE, post village, on a branch of Lehigh river, and in the southeastern part of Luzerne county, Pennsylvania, 18 miles SE. by E. from Wilkes-barre, 40 miles NW. from Easton, and by post road 239 miles NNW. from Washington city.

STOKES, county of North Carolina, bounded by Rockingham NE.; Guilford SE.; Davidson S.; by Yadkin river, which separates it from Rowan, SW.; and Surry W.; by the northern part of Surry NW.; and by Patrick county, Virginia, N. Length from south to north 38; mean breadth 24, and area 912 square miles. Extending in lat. 36° 02′ to 36° 30′, and in long. from 3° 32′ W. from Washington city. This county is a table land, from which flow Dan river from the northern part; different branches of Haw river from the southeastern; and some confluents of the Yadkin from the southern and southwestern. The soil is excellent. Germantown, the county seat, is situated near the centre of the county, at N. lat. 36° 20′, long. 3° 18′ W. from Washington City, by post road, 355 miles SW. from Washington City, and 127 NW. by W. from Raleigh. Population of the county in 1820 was 14,033.

Besides Germantown, there are post offices at Belew's Creek, Bethenia, Blakely, Boyle's store, Chesnut Ridge, Dobson's Cross Roads, Frost's iron-works, LittleYadkin, Red Shoals, Salem, Waughtown, and Webb's. Darby.

STONE, a town of England, in the county of Stafford, is situated on the northern bank of the Trent. It consists chiefly of one long street, with a new market-place, and several very excellent houses. The church is a neat building. There is a free school, and an endowed almshouse, a considerable manufactory of shoes, and one of patent roller pumps. In 1821, the population of Stone was, houses, 532; families, 555; ditto in trade, 269. Total population, 2855.

[STONE RIVER of Tennessee, interlocking sources with Duck river and with Stoney Fork river, and flowing northwestward, falls into Cumberland river, 6 miles above Nashville. The valley of Stone river and Rutherford county are nearly commensurate. The county from its outline has been evidently laid out with reference to the surface drained by this stream.] Darby.

STONEHAVEN, or Stonehive, a sea-port town of Scotland, in the county of Kincardine, is situated on the east coast at the junction of the waters of Cowie and Carron. The old town lies on the south bank of the Carron, and the other is a peninsula formed by the Coure and Carron. The old town has two considerable streets, and the new town, feued by Mr. Barclay of Urie, has a square in the centre, with broad streets on a regular plan. The harbour is formed by an inland basin defended on the SE. by a high rock, which extends into the sea, and on the N.E. by a commodious quay. As the mouth of the harbour is beset with submerged rocks, it is not very safe, though capable of great improvement. The brown linen manufacture has been for some time established here, and the trade of the place is considerable. The Sheriff Court of Kincardineshire is held here. The public revenue is £.45. The population is about 2000.

STONEHENGE. See Wiltshire.

STONINGTON, post town, borough and sea port, in the southeastern part of New London county, Connecticut, 10 or 11 miles a little S. of E. from New London, and 55 SE. by E. from Hartford. N. lat. 41° 19′, long. 5° 07′ E. from Washington City. Stonington was incorporated as a borough in 1801, and in 1820, contained, independent of the residue of the township, 800 inhabitants, one cotton factory, two woollen factories, an academy, and two or three places of public worship.

STORNOWAY. See Lewis, Vol. XII, p. 17.

STOURBRIDGE, a market town of England, in the county of Worcestershire. It is situated on the river Stour, over which there is a good stone bridge. It consists of several irregular streets on the road to Kidderminster, the chief of which contains many good houses. The church is a plain building. There are also chapels for presbyterians, quakers, and methodists. A theatre was built in 1790. The free grammar school founded by Edward IV. is well endowed, and managed by eight governors. The town is governed by a bailiff, a town clerk, and other officers.

Stourbridge has been long celebrated for its manufactures. The chief one is that of glass, which is carried on in *ten* glass houses, where broad glass, flint glass, and a kind of transparent red glass are made. Owing to the number of iron works in the vicinity, nails, agricultural implements, and other articles of ironmongery are manufactured in the town. Here are also manufactories of crucibles, stovepots, bricks, and tiles. Broad and narrow cloths are likewise manufactured here, and leather from sheep skins. Coal, iron ore, and clay, are found in the neighbourhood. The clay, which is unrivalled, is found at the depth of 150 feet, beneath three different strata of coal. It occupies 200 acres, 48 of which contain clay of a very superior quality, and not less than 1000 tons of it are annually taken up. The Stourbridge canal unites that town with the great lines of inland navigation. The population in 1821 was

Number of houses, -	979
Number of Families, -	1081
Number in trade, -	1034
Total population in 1821, -	5090

STOURPORT, a market town of England, in Worcestershire which has sprung up since 1771 in a barren heath. The town is handsome, and even elegant, and the houses in it are commodious. The streets are full of shops and thronged with people. The principal objects here are a handsome chapel of ease, and the iron bridge over the Severn. It consists of one arch of 150 feet span, and 50 feet above the water. The avenues to this main arch consist on both sides of a long range of smaller ones of brick, extending on the whole between 600 and 700 feet. The toll has been farmed at £ 500 per annum. Population 3000.

STOW MARKET, a town of England, in the county of Suffolk. It is situated on the river Gipping, and is a flourishing place, with several excellent houses. The church is a handsome building, with a wooden spire 120 feet high. The house of industry for the hundred, which is an elegant building, stands about a mile from the town. There is here a manufacture of ropes and sacking. From fifteen to twenty houses are engaged in the malting trade. The population of the town in 1821 was 2250. See INLAND NAVIGATION, Vol. XIV. p. 281, for a notice of the canal to Stow Market.

STRAFFORD, county of New Hampshire, bounded, by Rockingham, S.; Merrimack SW.; Grafton W. and NW; White Mountains separating it from Coos N.; Oxford county, Maine, NE.; and York county, Maine, E. and SE. Length from Great Bay to the White Mountains 70 miles; mean width 21, and area, 1470 square miles. Extending in lat. from 43° 04′ to 44° 03′, and in long. from 5° 13′ to 6° 06′ E. from Washington City. The northern part, along and near the base of White Mountains, gives source to Saco river, which flows eastward into Oxford, Maine; southward of Saco rises Great Ossipea river, also a branch of Saco, and flowing eastward into Maine, separates Oxford and York counties. The northwestern and western border is drained into Merrimac river. The central section is occupied by Winepisseogee lake and its confluents. This curious and irregular sheet of water is about 22 miles long, with a breadth varying from one to eight miles. It is discharged into Merrimac river by Winepisseogee river. The southeastern angle toward Great Bay is drained by some creeks of Piscataqua.

The general declivity of this county is southward. The surface hilly, and rocky, and in part mountainous. Soil productive in grain and pasturage. The courts are held alternately at Dover and Guilford. Dover is situated on Concheco river, by post road 40 miles E. from Concord, the seat of government of the state. Guilford is on the left bank of the Winepisseogee river, 30 miles a little E. of N. from Concord. Besides the two county towns there are 50 other places, each having a post office. This large county in 1820, contained 54,617, or something above 34 to the square mile. DARBY.

STRALSUND, is a sea-port town of Germany, and the capital of a government of the same name belonging to Prussia. It is situated in the strait which separates the island of Rugen from the main land. From the sea it has a good appearance, but upon a nearer approach its aspect is gloomy, from the narrowness of the streets, and the lowness of the brick houses, which are pointed at the top. It contains four Protestant and one Catholic church, two of which, the cathedral and the church of St. Mary, are handsome. In the former the baptismal fonts, the altar, and the lamps, are worthy of notice; and in the latter the paintings and the organ. The principal public buildings are the government house, the governor's house, the town-house, the arsenal, and the mint. The town-house is a singularly beautiful Gothic building, in a very peculiar and remarkable style. There are here an academy, a public library, an orphan house, a poor house, and a lunatic hospital.

The harbour of Stralsund is safe and capacious. Kuttner remarks that he saw more vessels in it than in any of the ports of Sweden or Denmark, excepting Stockholm, Copenhagen, and Gottenburg. Vessels of more than fifteen feet draught of water are obliged to unload in the roads. The chief manufactures are woollen and linen goods, tobacco, soap, glass, and earthenware, with breweries and distilleries. Ship-building is also a considerable branch of trade. The principal article of export is corn, of which about 35,000 quarters are annually exported. It is, however, inferior in quality to that of Mecklenburg. The imports are principally colonial produce and foreign manufactures. From being bounded at one part by the sea, and other places by lakes and marshes, it is accessible only by bridges. Before 1807, it was a well fortified town, but since then the works have been in a manner dismantled. The town is supplied with water by hydraulic machinery, near the Gate of Kuter. The promenades are the Gardens of Westphal, of Richter, of Hagemeister, and of Wolff. Population 10,000, exclusive of the garrison.

STRANGE, SIR ROBERT, an eminent Scottish engraver, was born in the Orkney Isles in 1721. He entered into the rebel army in 1745, and after its discomfiture he went to France. Having returned to England in 1751, he became the head of historical engraving in this country. He died in 1792, leaving behind him the reputation of great talents, and a good character. See ENGRAVING, Vol. VIII. p. 641.

STRANRAER. See WIGTONSHIRE.

STRASBURG, a city of France, and capital of the department of the lower Rhine, is situated at the junction of the Brusche and the Ille, about half a mile from the Rhine. The town occupies a space of a semicircular form, and is intersected by canals crossed with bridges. The houses, built in the German fashion are high, massy, and consist of a soft red stone. The great street, and a few others, are regular and spacious, but the rest are exceedingly narrow: The number of streets are said to be 200. The *Place D'Armes*, a square, surrounded with trees, contains some good buildings. The town is defended by a regular Pentagon, composed of five bastions and five half-moons. Its citadel lies towards the east, and its outworks reach almost to the Rhine. There are six bridges across the Ille, two of stone, and four of wood, and a wooden one 3900 feet long, across the Rhine, supported in the middle by an island on which is a strong castle.

The principal public building is the Gothic cathedral, founded in 1015, and finished in 1275. Its steeple terminating in a pyramid, is 470 feet high; is ascended by a stair of 635 steps, and is the highest in the world, excepting the great pyramid, which exceeds it by about 30 feet. The tower has the openness of lacework. During the revolution many of the ornaments together with its statues were destroyed. The clock which exhibits the movements of the planets, was made in 1571. The church of St. Thomas contains the mausoleum of Marshall Saxe. The other public buildings are the town hall, the episcopal palace, the arsenal, the foundling hospital, the town hospital, the public granaries, the theatre, the observatory, and the monument to General Dessaix.

Strasburg possesses several small manufactories of common cloths, lace, skins, pens, hats, candles, hair powder, artificial flowers, cutlery, paper hangings, vermilion, &c. The articles of export are corn, beef, flax, wine and spirits, likewise linen, blankets, carpets, and hardware, leather, cotton, and tobacco.

The establishments for education, &c. of Strasburg, are the Protestant gymnasium, conducted by ten professors, the central school of the department, the school of medicine, the society of arts and sciences, the free society of agriculture, an anatomical theatre, two public libraries, the physical and natural history cabinets, cabinets of antiquities and mechanics, and a botanic garden. Strasburg is the seat of a bishop, and the capital of the department of the lower Rhine. Population in 1827, 49,708. East Long. 7° 51′ 51″, and North Lat. 48° 31′ 56″.

STRATFORD upon Avon, a market town of England, in Warwickshire, celebrated as the birthplace of Shakspeare. It stands on the west bank of the Avon, which is here crossed by a bridge of thirteen large and six small arches, and 1123 feet long. There are twelve streets, several of which meet in a point like the rays of a star. The chief buildings are the church, and the town hall, the former is the place of Shakspeare's interment, and the latter contains excellent portraits of Shakspeare and Garrick, by Wilson and Gainsborough. The town is governed by a mayor, recorder, high steward, 12 aldermen, and 252 capital burgesses. By means of the Stratford on Avon canal, large quantities of millet and corn are here exported. Population in 1821, 3069. For farther information of Stratford, see Mr. Wheler's *History of Stratford*, 1806, and his *Guide to Stratford*, 1814.

STRATFORD Stony, a town of England, in Buckinghamshire, is situated on the Avon, which is here crossed by a stone bridge. The houses which are of freestone, extend about a mile on each side of the road. The church of St. Giles is neat, and there is a good market town. The principal occupation of the people is that of lace making. The population in 1821 of the west side and east side parishes, was 1449 inhabitants.

STRENGTH OF MATERIALS.

Under the article Carpentry, we have taken a concise view of the strains to which timber and other materials are exposed in buildings and other constructions, and have promised our readers to enter upon the subject again more at large in a subsequent part of our work, a pledge which we propose to redeem in this place. At the time that article was written, we could not but regret the poverty of direct information to be obtained as to the absolute experimental strength of various materials of common application in the arts, and we expressed our hopes that something of this kind would be undertaken by some of our scientific men, in order that the practical mechanic might be furnished with principles on which he might place reliance, and not be left to the mere result of his own experience. Since that time much has been done towards obtaining the data then so much wanted, first by Mr. Barlow of Woolwich, who obtained permission from the navy board to make any selection of timber, and to avail himself of any facilities which the dockyard at that port might furnish for carrying his views into execution. These results, with a pretty general abstract from most preceding experimenters, have been published by him in his "*Essay on the Strength of Timber, &c.*" which contains also a valuable set of experiments made by Thomas Telford Esq., and another by Captain Brown (the ingenious inventor of iron cables) on the direct strength of malleable iron. Mr. Tredgold also in his *Principles of Carpentry*, and in his *Treatise on the Strength of Cast Iron*, has added much important information on these subjects, as has also John Rennie, Esq. in the Philosophical Transactions for 1818, and lastly, Mr. Hodgkinson in volume fourth of the Manchester Memoirs, has given us a detail of various experiments of this kind which cannot fail of being considered highly curious and important. From these sources we shall in the present article endeavour to make such a collection of results as to furnish the practical builder and engineer with data on which he may securely depend, and rules proper for making the requisite computation in any new case that may present itself.

The following divisions are generally made of the various strains to which materials are exposed.

1. They may be drawn asunder by a force acting endwise.

2. They may be compressed and destroyed by a force acting also endwise.

3. A bar of any substance may be strained laterally, one part being supported, and the strain applied immediately at the point of the support, as when a tenon breaks or a rafter fails at the wall. If the material is cast iron or any similar substance, viz. non-fibrous, the direction of the force with respect to the body is important, but in fibrous bodies, as timber, this strain may be considered under two distinct heads; accordingly as the force acts perpendicular to, or parallel with, the direction of the fibres.

4. A bar or beam may be strained transversely, as in the case of a girder or rafter.

5. It may be twisted, as in the axle of mills, &c.

6. It may be strained by any two or more of these forces combined.

7. A material may also be strained by an internal pressure, as in the case of hydraulic cylinders, pieces of ordnance, water pipes, &c.

We shall consider each of these strains in the order in which they are stated above, and make such additions to the results given under the article carpentry, as are supplied by the recent experiments to which we have referred, and as these have generally been made with more precautions, with better means, and on larger specimens, we beg distinctly to state, that where these results differ essentially from the former, there can, in our opinion, be no doubt that the greatest confidence is due to the latter, we shall therefore generally omit all early and doubtful results.

1. *Of the resistance to extension in length arising from the direct cohesion of the fibres or particles of matter.*

As far as the mechanism of this strain is concerned it is the most simple of any of those above enumerated, but it is by no means the easiest to submit to experiment, particularly in timber, because, if the force is not directly opposed to the fixed point, the fibres are liable to be destroyed by a twist or strain different from that we are endeavouring to estimate; it is probably to this circumstance we must attribute the discordance observed in the results obtained by different experimenters; and it is for this reason we have thought it right to inform the reader of the means employed to assure accuracy in this respect in making the following experiments. Referring to Fig. 1. Plate AB represents one of the pieces whose strength is to be determined, its whole length being twelve inches: the length of each square three and a half inches, and the side of the square one and a half inches: the intermediate part, five inches, was turned in an excellent lathe and by a good workman, and brought down in the centre to one-third or one fourth of an inch in diameter, its exact diameter being ascertained by winding a piece of silk ten times round the circumference, which length divided by ten, gave the circumference, and hence the diameter was computed. The other cylindrical parts were each three-fourths of an inch in diameter. CC, DD, Fig. 2, represent two strong iron bars brought to the form shown in the drawing, GG, are two screws which are passed through the holes HH, in the bar DD, and are there screwed fast by the nuts II; EE are two semicircular collars rivetted, one to each bar, which, when the two are screwed together, form a circular plate, as represented in Fig. 4. The circular hollow parts *ee*, are three-fourths of an inch in diameter, so as to fit exactly the larger part of the cylinder shown in Fig. 1. These bars, after being screwed together, were rested on the supports as in Fig. 4, and then *brought out of winding* and accurately adjusted to a horizontal position by a spirit level.

The two iron boxes, MNO, M'N'O', Fig. 3, were made exactly to fit the square head B of Fig. 1, having also two semi-circular holes at the top correctly fitted to the larger part of the cylinder: these were shut by passing the bolts M'N' through the holes NM, and were thus secured by the shears shown in Fig. 4. In making the experiments, the head A of Fig. 1, was placed above the collars EE, Fig. 2, the upper larger cylindrical part of Fig. 1 being placed in the hollow parts *ee* of Fig. 2, when the two parts were securely fixed together by the nuts and screws IG, IG. In the same manner, the lower end of Fig. 1, was enclosed in the two iron boxes MNO, M'N'O' Fig. 3, and fastened in that position by means of the bolts M'N', and the shears above described. The whole were then rested on the props Fig. 4, and the hook of the seals being inserted in the circular hole formed by OO' Fig. 3, the whole was ready for the experiment as shown at large in the former figure.

Every thing being thus prepared, the wedges shown in the plate were introduced under the scale to keep it steady, while the larger weights were put in. The wedges were then removed, and smaller weights added in succession till the fracture took place. As a small vibration in the scale might cause a fracture in the small cylinder submitted to the operation of the weight, four small braces were made use of, one at each corner of the scale, to prevent any such motion; and every other possible precaution was had recourse to in order to ensure accuracy in the results, which in this case was the more necessary, as these were afterwards to be introduced in order to examine some of the more complicated strains and resistances. The following are the principal results obtained in these experiments, the smaller cylinders being reduced to what they would have been on square inch bars: it being assumed that the strength or resistance is proportional to the section of fracture, of which, it is presumed, no doubt can be entertained, it should be observed that these were select specimens of timber which had been a long time in store and perfectly dry.

These experiments were made, as is above stated, upon select specimens, and, therefore, exceed the general strength of wood of their respective descriptions; but, on the other hand, they were made with great care, and the general uniformity in the strengths of the similar specimens shows, that we may place great reliance on the results. These strengths, in the nearest round numbers, may be stated as below.

Box,	20,000	lbs. per square inch.
Ash,	17,000	
Teak,	15,000	
Fir,	12,000	
Beech,	15,000	lbs. per square inch.
Oak,	10,000	
Pear,	9,000	
Mahogany,	8,000	

The results, and the description of the apparatus, are taken from Barlow's *Essay on the Strength of Timber*, and they may, it is conceived, be considered perfectly satisfactory; therefore, where former results differ widely from these, they will be best omitted; for it is difficult to say whether furnishing a practical man with no information on this subject, or giving him a variety of discordant results, is most injurious? For this reason, in the following table we have omitted all those experiments given by Emerson and by Anderson, commonly found in our books: they are both clearly very inaccurate, unless they are meant to indicate the strain that may be safely borne, and not the ultimate strength, which probably is the case. In ascertaining the direct cohesive power of metals, much less delicacy of operation is required, because they are not so liable to rupture from a want of direct application of the power; but, on the other hand, they are generally made on specimens which require great force to break, and some inaccuracies are thus introduced into the results. A remarkable case of this kind occurs in the experiments reported in the preceding work, made by Mr. Telford, at Brunton's cable manufactory, and those made at Captain Brown's manufactory; the specimens of iron were the same, yet the results differed in about the ratio of 29 to 25. Mr. Barlow has shown the discrepance is most probably due to the two machines: In Brunton's experiments the machine employed was an hydraulic press, and the power exhibited by the small valve was opposed both to the friction of the piston, and to the bar, whereas it is supposed to be opposed only to the latter; this machine, therefore, overrates the power. Captain Brown's, on the contrary, was constructed on the principle of the weigh bridges, and, consequently, all the inertia was to be overcome before the exhibition took place in the register; we have, therefore, assumed the mean effect 27 as the truth, and have, accordingly, diminished the several results in Telford's experiments 7 per cent. and increased those of Brown's 8 per cent. They will thus be found to accord very nearly with some other experiments on which we have great reason to place reliance.

This being premised, the following tabulated results, will, it is presumed, be found highly valuable, and for which we are principally indebted to Mr. Tredgold, who has collected and arranged most of them in his edition of Buchanan's *Practical Essay on Mill Work*, and in his *Elementary Principles of Carpentry*.

In addition to the above table of the cohesive powers of different simple materials, we may add the following on the strength of iron and hemp, when manufactured into chain and rope.

Table of Experiments on the strength of chain made of various descriptions of re-manufactured iron (Foreign and British.) By Capt. S. Brown, R. N. from Barlow's Essay.*

Diameter of bolt.	Description of iron.	Breaking weight increased 8 per cent.†	
inch.		*tons.*	*cwt.*
$1\frac{1}{2}$	Old sable $1\frac{1}{2}$ inch square bar cut into two feet pieces, piled, and rolled into bolts,	82	14
$1\frac{1}{2}$	Ditto do.	90	0
$1\frac{1}{2}$	Gurcoft new sable, do.	79	17
$1\frac{1}{2}$	Keiolsken archangel inch square bars, cut and rolled as above,	79	17
$1\frac{1}{2}$	Old bolt taken promiscuously, piled and faggotted by hand hammers,	80	9
full $1\frac{1}{2}$	English bars piled and rolled,	96	15
bare $1\frac{1}{2}$	Ditto do.	90	0
$1\frac{1}{2}$	Old Dutch bolts faggotted by hand hammers,	79	17
$1\frac{1}{2}$	No. 1, 5-8 inch Welsh iron, hammered into bloom, and rolled into bolts at King and Queen works,	88	16
$1\frac{1}{2}$	No. 2, $\frac{3}{4}$ inch Welsh iron, manufactured as above,	82	8
$1\frac{1}{2}$	No. 4, Welsh iron faggotted and hammered at Captain Brown's works,	99	11
$1\frac{1}{2}$	No. 6, 5-8 ditto rolled but not hammered, at King and Queen works.	85	10
$1\frac{1}{2}$	King and Queen scrap iron,	90	6

The mean of these experiments give about $85\frac{1}{4}$ tons for the strength of a double bolt of $1\frac{1}{2}$ inch diameter, which is about $24\frac{1}{3}$ tons per square inch, whereas from a mean of the experiments at Messrs. Brunton's and at Capt Brown's manufactory, the strength in the simple bars is about $27\frac{1}{4}$ tons per square inch, hence the strength of iron manufactured into chain without stays to the link is to that in the simple bolt at $24\frac{1}{3}$ to $27\frac{1}{4}$, viz. it loses about 11 per cent of its strength; but when protected by stays, the loss is scarcely two per cent.

Table showing the different kinds of best bower cables at present employed in the British Navy, with the corresponding Iron Cables, their respective strengths, and Rope of different dimensions.

The above are, we believe, the most extensive and best authenticated results relative to the strength of the direct cohesive powers of materials any where collected, and will, we are persuaded, be highly useful to persons having occasion for any reference of this kind, for by a general comparison of all that has hitherto been given on this subject, we have been enabled to detect the erroneous results, (generally arising out of the employment of too small specimens) and have not introduced them into the tables.

It will of course be seen, that in this simple strain the resistance is proportional to the area of section, and that the strength of any sized rod of any material given in the table may be found by multiplying the area of section in inches by the strength per square inch, as given in the table.

Of the Resistance of Materials to Compression, or to a Crushing Force.

The exciting force in this case acts directly the reverse of that in the preceding section, but its effect is by no means so simple and defined. There are, in fact, here two cases to be separately considered, one when the body acted upon is too short to bend, and the other when it is of considerable length with regard to its other dimensions. In the former case, the mate-

* The links of these chains were of an oval form: greatest interior diameter six inches.

† The machine underrates itself 8 per cent, see p. 497.

rial is destroyed by actual pressure; but in the latter, it generally bends in one or more directions, and is ultimately broken by a force similar to that exerted by a transverse strain; it will be better therefore to reserve the latter case till we have treated of the transverse strain, and confine ourselves here merely to the crushing force, on which subject the following valuable table of experiments have been published by John Rennie, Esq. in the Philosophical Transactions for 1818.

The above experiments, although they will certainly be found useful in many inquiries, are not so valuable to an engineer as those given in our first section, because we cannot in the same way establish a general rule to derive from them the resisting power of similar materials in similar blocks. In the former case, there can be no doubt that the strength varies directly as the section, but in this it varies in a much higher ratio, and we are unable from theoretical considerations alone to ascertain what that ratio is. It is obvious, that as we increase the base of our specimens, the interior particles in granulated substances, and the fibres in fibrous bodies, are protected from yielding by the lateral resistance of the exterior ones; and to what extent this proceeds as we increase our dimensions, it is impossible to estimate, because so much depends upon the internal structure of the body. By comparing the first set of Mr. Rennie's experiments on cast iron with his third, fourth, or fifth, it would appear that the resistance is as the cube of the side; but we can by no means lay this down as a general law.

When wood is submitted to this strain, its destruction takes place by separating the fibres from each other, the lateral adhesions being altogether destroyed, (the pressure being endways of the grain.) Mr. Smart, the ingenious inventor of the hollow masts, and the patentee for the compression of wood in the formation of casks, canteens, saddle-trees, &c. has several curious specimens of compressed wood, in which the fibres are reduced nearly to the state of a painter's brush, by the separation of them as above stated.

Of the Cohesive Powers of Wood resisting a force acting Perpendicular to the Direction of the Fibre.

On this subject very little new matter can be collected to add to that given under the article carpentry; for although numerous experiments have been made since that article was written, on most of the other strains to which materials are exposed, this has been almost wholly neglected. We know of nothing that has been done, except two or three experiments by Mr. Tredgold, and one by Mr. Barlow, which latter, however, was on the lateral adhesion of the fibres, but those of the former were made on their transverse strength; these are as below.

	Kind of Wood.	Resistance on a square inch.	
	Oak	2316 lbs.	Tredgold.
	Poplar	1782 lbs.	
	Larch	from 979 to 1700.	
Lateral adhesion of	Fir	600	Barlow.

If we allowed ourselves to form any general estimate from these few experiments, we might say that the resistance to the strain across the fibres is about double that of the direct cohesion, but that the lateral adhesion is only about one half of the direct strength. We cannot, however, state this as correct in all cases, nor even as approximative; a few experiments on this subject would be highly interesting.

On the Resistance of Timber and other Materials to a Transverse Strain.

We have entered at some length upon this subject, under the article Carpentry, having there examined the result of all the most common strains of this kind to which materials may be exposed; but as in the preceding cases we had not then the means of furnishing satisfactory experimental data for computing the amount of the resistance, the dimensions of the timber being given, or for computing the dimensions requisite to resist any proposed strain or load, we shall therefore principally confine ourselves in this place to laying before our readers such experimental results, as will enable them to submit the principles laid down in the article quoted to practical cases, with such few additional rules as may appear necessary.

It is shown, article Carpentry, p. 502, that the strength of a rectangular beam to resist a transverse strain varies directly as the breadth and square of the depth, and inversely as the length; consequently, if from a series of well-conducted experiments we have been enabled to determine the breaking weight on a piece of timber, of any given species and of given dimensions, we may thence compute the weight necessary to break a piece of timber of the same kind, loaded in a similar way, and of any dimensions whatever.

It has also been demonstrated in the same article, that the strains upon a beam fixed at one end in a wall, and loaded at the other, is four times greater than when the same weight is hung upon the middle of the same beam, and the latter supported at its two extremities.

It has also been shown experimentally that when a beam is fixed at both its extremities in a wall, and loaded in the middle, its strength is to that, when only supported at its two ends, as 3 to 2.

And lastly, that when a weight is uniformly distributed over a beam, its mechanical action to produce fracture is only one half of what it is when collected in the middle.

It follows, therefore, that from a series of experiments made on the resisting power of timber or other material, in any one of these cases, the resistance in any other may be found, or rather perhaps we ought to say, that the resistance in all of them is the same, it being merely the strain that is altered by the different modes of fixing and loading. Let l = the length, b the breadth, and d the depth of any rectangular piece of timber, all in inches, and W the weight in pounds, requisite to break it. Let also S be the weight requisite to break a piece of similar timber, whose length, breadth, and depth, are each one inch, then form our first rule.

$$\text{As } \frac{bd^2}{l} : 1 :: W : \frac{lW}{bd^2} = S$$

Which S will be a constant number of reference for computing the strength of any piece of timber of the same kind, under all variety of dimensions and modes of fixing and loading.

Suppose, for example, this constant is formed for the case in which the beam is fixed at one end and loaded at the other, and the weight W were required that would break any given beam, under any of the circumstances stated above, then we should have

1. Beam fixed at one end, and loaded at the other

$$W = \frac{S\,b\,d^2}{l}$$

2. Beam fixed at one end and loaded uniformly throughout $W = \frac{2\,S\,b\,d^2}{l}$

3. Beam supported at each end and loaded in the middle $W = \frac{4\,S\,bd^2}{l}$

4. Beam supported as above and loaded uniformly

$$W = \frac{8\,S\,bd^2}{l}$$

5. Beam fixed at each end and loaded in the middle

$$W = \frac{6\,S\,bd^2}{l}$$

6. Beam fixed as above and loaded uniformly

$$W = \frac{12\,S\,bd^2}{l}$$

And in the third and fourth cases, if the load be applied in any other point than the middle, then calling m and n the distance from the ends. The above results are to be respectively divided by $\frac{4\,mn}{l^2}$ for the resistance in these cases, which thus become

$$W = \frac{S\,l\,b\,d^2}{m\,n} \text{ and } W = \frac{3\,S\,l\,b\,d^2}{2\,m\,n}$$

It has been explained under Carpentry that we ought to proceed correctly to introduce into these formula the cosine of the beam's deflections, but this leads to considerable intricacy, and is of little value, because we do not generally require to know the actual but relative resisting power, and in all practical cases the deflection is too inconsiderable to be regarded. Indeed it has been asserted that our inquiry ought not to be directed to the ultimate strength; we think, however, that it is desirable in all cases to know what this is, and we may then keep as much within the limits as we please, or as the case seems to require.

The following table, containing the value of S, deduced from a variety of well conducted experiments, is taken from Tredgold's "Elementary Principles of Carpentry." We have only multiplied that author's constant by 3, to make it correspond with our constant denoted above by S, and added a few other results from Barlow's Essay on the Strength of Timber, &c.

Table exhibiting the experimental strength of various species of Timber opposed to a transverse strain.

Comparing the relative strength of oak and cast iron to resist a transverse strain, it appears that the latter is about five times that of the former, while its direct cohesive power is not more than one and a half times, and its weight is about eight or nine times greater than an equal bar of oak.

The application of the numbers given in the above tables to the formula preceding them, is so obvious as to require very little further illustration, we shall therefore confine ourselves to a single example.

To find the weight which, (applied at the centre of a rectangular beam supported at both ends, and of given dimensions,) is necessary to produce fracture.

The rule, in words, is here obviously as follows: Multiply the breadth by the square of the depth, and again by four times the constant value S of the particular material given in the table. Then divide the product by the length, in inches, for the weight required.

Example. What weight would it require suspended as above, to break a teak beam twenty feet long six inches broad and ten deep.

Here $\frac{4\times6\times10^2\times2151}{240}=21510$ lbs.

If the beam were fixed at one end, and loaded at the other, then the co-efficient 4 is omitted, and the weight is $\frac{6\times10^2\times2151}{240}=5377$ lbs.

If, in the former case, the beam is loaded uniformly throughout, then by the formula the weight required is $\frac{4\times6\times10^2\times2151}{240}\times2=43020$ lbs.

Of the Stiffness of Beams in Resisting a Transverse Strain.

In the preceding section our inquiry has been directed to the ultimate strength of materials, viz. the greatest weight they will support, or rather, perhaps, the least weight that will destroy the beam; but this in general is not the information a practical man most requires, although, it is obvious, if he knows the ultimate strength, he may keep as much within those limits as his case may seem to require, and thus far the tables and rules laid down in the preceding pages will be found highly useful, but commonly it is not the strength but the stiffness of his beams and rafters, that is of greatest consequence to an architect or engineer for a certain deflection, in many cases, is nearly as dangerous or injurious as an actual fracture, we should therefore leave this subject incomplete, if we did not also furnish such experimental data connected with it, as have been obtained from the sources already referred to since our article CARPENTRY was published.

When a beam is supported at its two ends, and loaded either at its middle point or uniformly throughout, the centre of the beam will sink below the horizontal line, and this sinking measured where it is greatest, is called the *deflection*.

The *stiffness* of a beam is the proportion between its length and deflection, the weight and all other things being the same, therefore, when the length is different, and the stiffness the same, the deflection must be proportional to the length. Now, it has been found from numerous experiments, as well as from theoretical investigation, (see CARPENTRY *and Barlow's Essay*,) that the deflection of beams of the same material similarly loaded, varies as the weight and cube of the length directly, and as the breadth and cube of the depth inversely, or d varies as $\frac{l^3 \times W}{bd^3}$, but the stiffness is as the length, divided by the deflection, this therefore varies as $\frac{bd^3}{l^2 W}$. Let now d be an experimental deflection found to be due to a given length l, depth d, breadth b, and weight W and d', any proposed deflection with the same beam, to find the corresponding weight w that will produce it; this is found by the simple proportion $d : d' :: W : \frac{Wd'}{d} = w$. Then this value of w being substituted in the formula $\frac{bd^3}{l^2 W}$, (instead of W,) ought to produce a constant quantity $= a$, d, being always taken proportional to the length, and from this constant the proper dimensions in any other case may be computed.

Mr. Tredgold has computed the value of the constant a, when the deflection is 1-40th of an inch to a foot, or 1-480th of the length, from the experiments reported in the following tables, consequently his constant is obtained by the formula $a = \frac{40bd^3\delta}{l^3 W}$.

The application of the results contained in the preceding table is sufficiently obvious, at least while the deflection is intended to be $\frac{1}{480}$th of the length, and if in any case a greater deflection be admissible, or a less be requisite, it is only necessary to find a new value of a from the tabular one, by saying, as the proposed deflection, divided by the length, is to $\frac{1}{480}$, so is the tabular value of a to the value sought; with which proceed according to the following rules or formula:

When the length, breadth, and weight are given, to find the depth then

$$d = \sqrt[3]{\frac{a\,l^2 W}{b}}$$

When the length, depth, and weight are given, to find the breadth $$b = \frac{a\,l^2 W}{d^3}$$

These are the only cases which arise in practice, and the numerical operations are sufficiently evident without any numerical examples.

On the Resistance of Columns to a Vertical Pressure.

We have already given a detail of various experiments on the force requisite to crush certain materials, but in the case here to be considered the material is not destroyed by the actual crush, but by a flexure which always takes place, and after which the mechanism of the operation resembles that already considered, under the denomination of the transverse strain. The results, however, from actual experiment, are, in this case, by no means so uniform as in the former; and theory, it must be acknowledged, can assist us but very little, because theory always supposes an uniformity of result in practical cases, where all the conditions are the same, but here with two trees, of the same wood, the same specific gravity, and the same dimensions, owing to some internal and hidden cause, will give results very wide of each other; the bending will take place in different parts and in different directions, and the fracture produced by different weights. It is therefore only within certain limits that practical rules can be laid down in these cases. In pieces of timber submitted to a transverse strain, the effect of the weight is greatest in a certain and determinate point, and if the material be sound at that place, a defect in another part is seldom of any consequence; but when the whole piece is submitted to pressure endwise, every defective part has an influence in the operation; and to this cause may be principally attributed the irregular nature of results obtained in experiments of this description. Therefore, in stating the following principles of computation, the reader will be aware that the same security cannot be placed in them as in those which have preceded, and that they are only applicable when the timber is uniformly sound throughout. They may be stated as follows, viz.

The resistance to flexure varies directly as the breadth into the cube of the depth, or as the least dimension into the cube of the greater;

And the strain varies as the square of the length into the weight;

Consequently, if we have a series of experiments, showing the flexure which has been produced by certain weights in beams of given dimensions, we may hence compute the weight that would produce any other given flexure, and hence again the length and weight, in any other case, being given, we may compute the requisite breadth and depth, these being either equal, or bearing any given proportion to each other.

The two following tables are of this description, the one extracted from "Construction des Ponts, &c." of M. Gauthey, and the second from the "Traité Analytique de la Resistance des Solides," by M. Girard, as they are given by Mr. Tredgold in his Elementary Principles of Carpentry. The elasticity e, however, as deduced from these experiments, the latter author considers too strong for general practice, and he recommends in practical cases to use the mean value $e=$ for oak, and this being assumed, he has computed the mean value for the other woods stated in a preceding table for the transverse strain; this table we have also given. And since, acccording to the preceding analogies, it appears that $\frac{b\,d^3}{l^2 W} = e$ or constant quantity, we shall have at once for computing the depth or least thickness of beams (all the rest being given),

$$d = \sqrt[3]{\frac{l^2 W e}{b}} \quad \text{or} \quad b = \delta \frac{l^2 W e}{d^3}$$

when d is given, and b the greater side is sought.

It appears also to have been determined that a column or cylinder has a less power of resistance than a rectangular beam (in which $b\,d^3 = D^4$, D being the diameter of a circle) in the ratio 1: 1.7, therefore for a cylinder, the formula for the diameter is

$$D = \sqrt[4]{(l^2 W \times 1.7\,e)}$$

also a rectangular beam is said to be weakest in the direction of its diagonal, and when square to require the multiplier 4, so that in a square beam

$d' = \sqrt[4]{l^2 W \times 4\,e}$, where d′ is the diagonal.

We have, in compliance with general practice, given these rules, the investigation of some of which may be seen in Tredgold's work above quoted, and in Dr. Young's Lectures on Natural Philosophy; but we have already stated our opinion of their inadequacy, that is, they would be true provided we could assume an uniformity of texture throughout, but this is seldom to be expected in practice. The tables, however, are computed on the lowest possible resisting powers, so that the dimensions determinable by the rules will never fail in point of strength, unless the timber be very deflective, and it is much better to have our dimensions in excess than our strength in defect. For the reasons stated in the preceding section, the numerical application of these tables and formula are omitted.

On the Resistance to Torsion.

Mr. Tredgold, in his Practical Essay on the Strength of Cast Iron, has the following illustration of the nature of this strain. If a rectangular plate be supported at the corner A and B, Fig. 5, and a weight be suspended from each of the other corners C, D, then the strains produced by loading it in that manner will be similar to the twisting strains which occur in shafts. In a cast iron plate, the fracture would take place in the directions AB, and CD, at the same time; but before the fracture, the ore of the strains will serve as a fulcrum for the other; and the resistance to the forces at C and D will be sensibly the same as if the plate were supported upon a continued fulcrum in the direction AB.

Hence, the strains may be considered as a transverse strain of the same kind as that already treated of with the leverage a D, or c C, acting at D or C, the breadth of the strained section being AB.

To find the breadth of the section of fracture, and the leverage in terms of the length and breadth of the plate, we have AB the breadth, and by similar triangles $\frac{AD \times BD}{AB} = D\,a$ the leverage. These values of the leverage and breadth being substituted in the equation, expressing the transverse strain, becomes

$$W \times \frac{b^6\, d}{b\, l} = \frac{f\, d^2 \times AB \times AB}{6 \times AD \times BD}$$

Or since $AB^2 = BD^2 \times AD^2$

$$W = \frac{f\, d^2}{6} \times \frac{BD^2 \times AD^2}{AD^2 \times BD}$$

But when a force acts upon a shaft, it is commonly at the circumference of a wheel, and if R be the radius of the wheel, then $\frac{2\, RW}{BD}$ = force collected at the surface of the shaft; substituting therefore this instead of W in the above equation, we have

$$\frac{2\, RW}{DB} = \frac{f\, d^2}{6} \times \frac{BD^2 \times AD^2}{AD \times BD}$$

$$\text{Or} \quad W = \frac{f\, d}{12\, R} \times \frac{BD^2 \times AD^2}{AD}$$

Experiments relating to Torsion.

The following experiments were made by Mr. George Rennie, and published in the Philosophical Transactions for 1818. The apparatus consisted of a wrought iron lever, two feet long, having an arched head of about 60°, and four feet diameter, of which the lever represented the radius: the centre round which it moved had a square hole made to receive the end of the bar to be twisted. The lever was balanced, and a scale hung on the arched head; the other end of the bar being fixed in a square hole, in a piece of iron, and that again in a vice. The following are the results of these experiments:—

It will of course be understood that these experiments give only the relative resistance to torsion, and not the actual resistance.

On the Resistance of Cylinders to Internal Pressure.

With respect to internal pressure, such as that sustained by water pipes, hydraulic cylinders, &c. we know of no actual experiments, but the amount of resistance is so directly dependent on the resistance to tension, that no experiments are in this case necessary. If we examine the force which tends to produce the rupture in this case, it will be seen immediately that it varies as the longitudinal section of the cylinder; or which is the same, the circumferential strain on any given point of the interior of the cylinder, is equal to the pressure on a square inch multiplied by the number of inches in the radius. That is, the force tending to rend the cylinder along any line parallel to its axis, is equal to a pressure on a section between the circumference and axis.

Hence it would appear at first sight that the determination of the thickness to resist this pressure would be simply to determine the sectional area of the metal requisite for this purpose, on the supposition of every part bearing an equal torsion: this, however, is not sufficient, and practice has pointed out that in presses and pipes, it is always necessary to increase the thickness in a higher ratio than the pressure. This subject has been investigated by Mr. Barlow, and the following is the result of his inquiries. If we imagine, as we ought to do, that the metal, in consequence of the internal pressure, suffers a certain degree of extension, it will be found that the external circumference participates less in this extension than the internal, and as the resistance is proportional to the extension divided by the length, it follows that the interior circumference, and every successive circular lamina from the exterior to the interior surface, offers a less and less resistance to the interior strain. The law of which it is our object to investigate.

In the first place, it is obvious that whatever extension the cylinders or ring may undergo, there will be still the same quantity of surface, independently of the small change due to compression, in the section of the ring, which area is always proportional to the difference of the squares of the two diameters.

Let D be the interior diameter before pressure, and $D + d$ its diameter when extended by the pressure.

Let also D' be the exterior diameter before pressure, and $D' + d'$, its diameter when extended by pressure.

Then from what is stated above we have

$$D'^2 - D^2 = (D' + d')^2 - (D + d)^2$$
$$\text{Or } 2\,D'd' + d'^2 = 2\,D\,d + d^2$$
$$\text{Whence } 2\,D' + d' : 2\,D + d :: d : d'$$

Or considering d' and d as very small in comparison with $2\,D'$ and $2\,D$, this becomes

$$D' : D :: d : d'$$

That is, the extension of the exterior surface is to that of the interior, as the interior diameter to the exterior,

But the resistance is as the extension divided by the length, therefore, the resistance of the exterior surface is to that of the interior, as $\frac{D}{D'} : \frac{D'}{D'^2}$ Or $D^2 : D'^2$.

That is, the resistance offered by each successive lamina is inversely as the square of its diameter, or inversely as the square of its distance from the centre; by means of which law the actual resistance due to any thickness is readily ascertained.

Let r be the interior radius of any cylinder, p the pressure per square inch on the fluid, t the whole thickness of the metal, and x any variable distance from the interior surface. Let also s represent the strain exerted, or the resistance sustained, by the interior lamina, then by the law last deduced

$(r + x)^2 : r^2 : s : \frac{r^2\ s}{(r+x)^2}$, the strain at the distance, a from the interior surface, consequently,

$$\int \frac{r^2\ s\ d\ x}{(r + x)} + cor. = \text{sum of all the strains.}$$

This, when $x = t$ becomes

$$R = r^2\ s\ \left(\frac{t}{r} - \frac{t}{r+t}\right) = \frac{s\ r\ t}{r+t}$$

That is, the sum of all the variable strains or resistances on the whole thickness t, is equal to the resistance that would be due to the thickness $\frac{r\ t}{r+t}$ acting uniformly with a resistance s.

Let us now suppose (the above law being established) the radius r, and the pressure p per square inch on the fluid, to be given, to find the thickness necessary to resist it, or such that the strain and resistance may be in equilibrio, the cohesive power of the metal being also given. Let x represent the thickness required, and c the cohesive power of the metal per square inch; then, the greatest strain the area $\frac{r\ x}{r+x}$ can sustain, is $\frac{r\ x\ c}{r+x}$, and that which it has to sustain is $p\ r$; hence, when these are equal we shall have

$$r\,p = \frac{r\ x}{r+x}\ c, \text{ or } p\ r + p\ x = x\ c$$

$$\text{Whence} \quad x = \frac{p\ r}{c - p}.$$

Hence the following rule in words at length.

To find the thickness of Metal.—Multiply the pressure per square inch by the radius of the cylinder, and divide the product by the difference between the cohesive power of the metal per square inch, and the pressure per square inch, and the quotient will be the thickness sought.

As an example, let it be required to determine the thickness of metal in two presses, each 12 inches in diameter, in one of which the pressure is $1\frac{1}{2}$ tons, and in the other, 3 tons per circular inch: the cohesive strength of cast iron being 18,000lbs. per square inch. Here $1\frac{1}{2}$ tons per circular inch = 4278 lbs. per sq. inch.
3 tons = 8556

Hence by the rule

$$\text{First } \frac{4278 \times 6}{1800 - 4278} = 1.87 \text{ inches thickness.}$$

$$\text{And } \frac{8556 \times 6}{1800 - 8556} = 543 \text{ inches thickness.}$$

It appears, therefore, that in this second case, although the pressure is only double the former, the metal requires to be nearly three times the thickness.

STROMA, see CAITHNESS, Vol. V. p. 132.

STROMBOLI, the most northerly of the Lipari Isles. It is about ten miles in circuit. The population of the island, amounting to about 1000 persons, are lodged in an irregular collection of cottages and fishermen's huts. A small portion of the island is cultivated, and the inhabitants are chiefly occupied in fishing. Rabbits are here abundant.

The island consists of a single conical mountain, having on one side of it several small craters, one of which is in ceaseless activity, having in all probability continued so during the last 2000 years. The mountain rises at an angle of nearly 40°. The crater is placed upon the slope of the precipice. The gaseous fluids escape from the volcano in successive explosions, the greater ones at intervals of about seven minutes, and the lesser ones almost continually. The lava is thrown out only as projected scoriæ, and is seldom or never discharged in any quantity. The inhabitants assured Mr. P. Scrope that in the storms of winter the side of the cone occasionally split, and discharged into the sea a current of lava which destroyed the fish.

Dr. Daubeny found that that part of the island not in the immediate vicinity of the volcano, was chiefly composed of a tuff. In one place the cavities were lined with very minute laminæ of specular iron. The tuff is in some places penetrated by dykes of a cellular description of rock approaching to trachyte.

According to Mr. Scrope, the lavas of Stromboli have a high degree of fluidity, as their cellular nature shows, and also an extremely high specific gravity, being solely augitic. East Long. 15° 55'; North Lat. 38° 58'. See Spallanzani's *Tracts*, vol. ii. and iv. Mr. Scrope's *Considerations on Volcanoes*. Lond. 1825, p. 6, 56. Dr. Daubeny's *Description of Volcanoes*. Lond. 1826, p. 183-186.

STROMNESS. See ORKNEY, Vol. XV. p. 78.

STRONSAY. See ORKNEY, Vol. XV. p. 81.

STRONTIAN, a small village in Argyleshire, situated on Loch Sunart, celebrated for its lead mines, and for having given its name to the new earth of Strontites, first analysed by Dr. Hope. The minerals found at this place will be learned from the list of Scottish minerals given in our article SCOTLAND, Vol. XVI. p. 697. See also Dr. Brewster's *Journal of Science*, Vol. I. p. 225, and CHEMISTRY, Vol. V. p. 685—706.

STROUD, a town of England, in Gloucestershire, situated near the junction of the Frome and Stroud Water. The houses stand irregularly on the bank of the river. The Church of St. Lawrence consists of a nave, chancel and side aisles, with a tower and spire. There are also chapels for the Wesleyan Methodists and Independents, a free school, and several charity schools. Stroud is the centre of an extensive trade in fine cloth, most of which is in grained colours, particularly scarlet, the water of the river being supposed particularly fitted for such purposes. All the surrounding vallies are covered with houses and villages, inhabited by those engaged in the manufacture. The Thames and Severn Canal gives great facility to the trade of the place. Population of the parish in 1821; 1419 inhabited houses; 1493 families; 1144 families employed in trade; and 7097 inhabitants.

STRUENSEE, John F. See Denmark, Vol. VII. p. 491.

STRYCHNIA, the name of a new alkali, which has been obtained from the fruit of the *Strychnos ignatia*, the *Strychnos nux vomica*, and from the *Upas*. It was discovered in 1818 by MM. Pelletier and Caventou.

The following process for obtaining it is recommended by M. Carriol. The solution of *nux vomica*, treated with successive portions of cold water, is evaporated to a syrup, and the gum precipitated by alcohol. The alcoholic solution is then evaporated to an extract by the heat of a water bath. This extract, which is the *Igasurate* of *Strychnia*, when deprived of a little fatty matter by solution in cold water, is heated and the strychnia precipitated by a slight excess of lime water, and then dissolved by boiling alcohol. By evaporating the spirit, the alkali is obtained nearly pure. It occurs in four-sided prisms. It is highly soluble in boiling alcohol, but almost insoluble in water, requiring 6000 parts of cold, or 2500 of boiling water. It is intolerably bitter, and water containing only one 600,000th part of the weight of strychnia, tastes bitter. It is united in the nux vomica with igasuric acid, the existence of which, as a separate acid, is still doubtful. This alkali affords a red colour with strong nitric acid.

It is a most virulent poison. Half a grain blown into the throat of a rabbit kills it in five minutes. It is composed of 78·22 carbon, 6·38 oxygen, 6·54 hydrogen, and 8·92 nitrogen. For farther information see Dr. Turner's *Elements of Chemistry*, 2d edition, 1829, p. 651. *Mem. de Chim.* vol. x. and xxvi. and *Journal de Pharmacie*, 1825, p. 492.

STUTTGARD, the capital of the kingdom of Wirtemberg, is situated in a valley on the banks of the Nisselbach, about two miles from the Neckar. It consists of the city, two well built suburbs adjacent to each other, and the insulated suburb of Esslingen. Some of the streets are broad, and others very narrow. The houses, which are chiefly of wood, are tolerably good. The principal public buildings are the palace, which is a splendid building, near an extensive park. It contains a fine library and collection of paintings. The library consists of above 100,000 volumes, among which is a very interesting collection of battles, and a collection of plans and military charts. Near the palace is a commodious opera house, a theatre, a museum of natural history, and an academy of paintings, sculpture and architecture. There is also at Stuttgard a gymnasium, a college, a society of physicians and lovers of natural history, founded in 1804. The collection of the old university still exists, and the natural history cabinet of Roesler now belongs to the gymnasium. The other public buildings are the old palace, the collegiate church, the hotel de ville, the barracks, the town library, the mint and the royal stables. In the environs of Stuttgard are the *Solitude*, the Hirschbad, and the palace of Ludwigsburg, with its fine collection of pictures, the park of Hohenheim, the Roman baths, the house for the orphans of soldiers, the prison and the porcelain manufactory. The chief manufactories are cotton, silk, hats, leather and snuff. Population, 18,000.

STYRIA, a large province of the Austrian empire, is bounded on the north by Austria, on the east by Hungary, on the south by Carniola, and on the west by Carinthia. It extends about 110 miles from east to west, and from 25 to 45 from north to south, and contains about 8500 square miles. It is subdivided into Upper and Lower Styria.

Upper Styria.	Lower Styria.
Circle of Iudenburgh.	Circle of Gratz.
Bruck.	Marburg.
	Cilley.

A branch of the Alps, rising in different parts to the height of 6000, 7000, 8000 or 9000 feet, extends through Upper Styria from west to east, part of them being covered with perpetual snow. The ramifications which are sent out into Lower Styria, gradually decline into small elevations. The principal rivers are the Drave, the Save, the Enns, and the Muhr. In Upper Styria, the climate is very cold, though the air is pure. The winter lasts from November till May, and as cottages are inhabited at very great heights in the mountains, the people are kept prisoners for several months when there are falls of snow. The steep declivities of these elevated regions are cultivated by the plough, and produce a fine species of wheat, which they are able even to export. The Styrians have large herds of cattle, on which they bestow much care, and they are well shaped and of a middle size. Sheep are not yet brought to great perfection, and the horses are fit chiefly for draught. There are here wild fowl, game, and the chamois, with abundance of fine fish in the mountain lakes.

In Lower Styria, wheat, barley, oats, rye, and potatoes, and, in warm exposures, maize, are cultivated. In some of the warm vallies very fine corn is successfully cultivated.

Styria abounds in valuable mines. Gold, silver, and copper occur in small quantities, but lead is scarce. Coal is wrought in some places, but not with the spirit which it deserves. The mountain of Erzeberg is a solid mass of iron ore, and yields annually 13,000 tons. The total produce of Styria in iron is from 16,000 to 20,000 tons. There are good salt works at Aussee, and mineral springs are numerous. Cobalt, arsenic, and molybdena, are found in this province.

There are in Styria 200 forges, and 30 manufactories, where about 300,000 sickles and some scythes are annually made. The other articles of manufacture are nitre, alum, gunpowder, and sulphur. Earthenware is also made, and some coarse linen. The imports are woollen and linen goods, silk, oil, tobacco, and colonial produce. The exports are iron, steel, sickles, scythes, corn, wine, flax, olive oil, and cattle. There are nearly 120 towns or little villages in the province, and 500 citadels, many of which stand on the highest summit of the rocks. Iudenburgh is the capital of Upper, and Gratz of Lower Styria. The people are principally Roman Catholics. About 15 inches of rain fall annually. Population about 840,000. See Gratz,

STYLE. See CHRONOLOGY, Vol VI. p. 252.

SUABIA. See SWABIA.

SUAKIN, or SUAKEM, a Turkish sea port town, and Island of Nubia, anciently *Theon Soter*. The town has an imposing appearance at a distance, from the effect of two minarets, but it is mean when seen nearer. The harbour is capable of holding 200 large vessels. Water and provisions are good. The town carries on a small trade with the coast of Africa, Arabia, and Egypt. East. Long. 37° 35. N. Lat. 19° 48.

SUBTRACTION. See ARITHMETIC, Vol. II. p. 357; and ALGEBRA, Vol. I. p. 403.

SUDBURY, a borough of England, in Suffolk, situated on the river Stow, which is crossed with a stone bridge, and occupying several irregular streets.

The principal buildings are the three parish churches of St. Gregory's, St. Peter's and All Saints, which are handsome, besides an ancient market house. The town has a considerable manufacture of toys, perpetuanas, buntings, and crape, and as the Stow is now navigable to Manningtree, an active trade is carried on in the produce of the neighbourhood. The town returns two members to parliament by the votes of 725 freemen. Part of the priory of St. Augustine, converted into a house, still exists.

The population of the borough in 1821.

Houses,	819.
Families,	955.
Do. in Trade,	671.
Population,	3950.

See the *Beauties of England*, vol. xiv. p. 147.

SUDERMANIA, or SUDERMANLAND, one of the middle provinces of Sweden, is about 100 miles long and about 55 broad, containing 3470 square miles. The mountainous part contains mines of lead, copper, iron and cobalt. There is much arable land, which is fertile and well cultivated. The principal lakes are the Maelar, which bounds it on the north, the Hielmar and Bawer, and many smaller ones, which abound in fish. Nykioping is the capital of the province. Population 156,000. See SWEDEN.

SUDEROE. See FAROE.

SUETONIUS, TRANQUILLUS CAIUS, a celebrated Roman author, was born A.D. 117. He was secretary to Adrian, but was banished from the court in consequence of disrespect to the empress. He enjoyed in seclusion the friendship of Pliny, and composed various works; the only one of which extant is his Lives of the Twelve Cæsars, with some fragments of his Catalogue of Famous Grammarians. One of the best editions of his work is that of Ernestus, Lips. 1775.

SUEZ, a town of Egypt, situated on the Red Sea, on the isthmus of the same name. It was the ancient Arsinoe. The town is supposed to have been built within the last 300 years. In the time of Niebhur it was as prosperous as Cairo, but it has since greatly declined, the French having destroyed one half of its houses, which then amounted only to 900. Vessels cannot approach nearer than about two and a half miles of the town. The country around is a desert; but there is still some trade with Gaza, Joppa, and Jerusalem, by caravans which bring soap, oil, and tobacco. Coffee, tea, pickled ginger and tamarinds are the chief exports. East Long. 32° 28′, and North Lat. 30° 1′.

SUFFOLK, a maritime county of England, is bounded on the east by the German Ocean, on the south by Essex, on the north by Norfolk, and on the south by the county of Cambridge. It is about 47 miles long and 27 broad, and contains 1,512 square statute miles, or 967,680 statute acres. The rental of land is £694,078 + £117,405 of tithe, and the annual value of a square mile is £537. In 1806 it paid £1,731,763 of property tax.

Suffolk is politically divided into the franchise or liberty of Bury St. Edmunds and the Geldable land; and though there is only one assize for the county, yet two grand juries are always appointed, one for the Geldable land, and the other for the liberty of Bury St. Edmunds. These are subdivided into 21 hundreds and 523 parishes. The county pays 20 parts of the land-tax, furnishes 960 militiamen, and returns 16 members to parliament, two for the county, and two for each of the towns of Aldborough, Dunwich, Eye, Ipswich, Orford, Sudbury, and Bury St. Edmunds.

The county is governed ecclesiastically by the bishop of Norwich, aided by the archdeacons of Sudbury and Suffolk. In 1803 the money levied for the poor was £149,666, or 4*s*. 10½*d*. per pound of annual rate.

Suffolk in general presents a level surface, diversified with but few eminences of any considerable height. The great chalk ridge extends from Haverhill to Thetford in the county of Norfolk.

Suffolk is bounded on the south and west by navigable rivers, and is intersected by numerous streams. The navigable rivers are the Lark which joins the Great Ouse near Mildenhall. The Waveny, which, after approaching the very sea-shore, is driven back abruptly by a rising ground, and runs due north to the Yar, the Deben, which passes Woodbridge and falls into the sea; the Gipping, which receives the name of the Orwell below Ipswich, to which it is navigable, and joins the Stour opposite to Harwich; the Blythe, which runs near Saxfield, and is navigable to Framlingham; and the Stour, which separates the county from Essex, falls into the sea, between Harwich and Landguard fort. The other rivers are the Little Ouse and the Alde. The only canal in Suffolk runs from Ipswich to Stowmarket.

The soil of Suffolk embraces almost every variety from the lightest sand to the heaviest clay; the former occurs principally in the northwest of the county, which is a dreary barren district, sustaining upon its patches of heath a few sheep and rabbits. Even here, however, by means of the free use of clay, much valuable land has been reclaimed. The interior of the county is a strong fertile loam, which rewards the skill with which it is managed by most abundant crops. The portion called High Suffolk has a very stiff and retentive soil, but yields fine wheat, oats, beans, hemp, and cabbage. The bean crops are highly productive. Turnips and carrots are extensively cultivated. Every garden rears a small portion of hemp, and a few hops are grown near Stowmarket. The seaward district is generally sandy, but it bears excellent barley when enriched with shell marl, which occurs in vast beds near Woodbridge. A small part of the county is fenny, and peat bog is in some cases found from one to six feet beneath the surface.

The farming stock of this county is highly valuable.

Suffolk furnishes an excellent breed of draught horses, which are strong, active, and capable of great exertion. The cows, which have no horns, are excellent milkers, yielding from five to eight gallons a day. The dairy district is extensive, and the quantity of butter sent annually to London is about 40,000 firkins. The sheep, which are very numerous, are chiefly of the Norfolk breed. Within the last 40 years the breed has been nearly changed by the introduction of the South Down breed, which was effected by Arthur Young. Hogs, poultry, and pigeons are numerous.

There are many rabbit warrens; one near Brandon yields 40,000 rabbits annually.

Suffolk has almost no manufactures, the woollen manufacture occupying in 1785 about 37,600 persons, having been chiefly transferred to Yorkshire. At Stowmarket coarse linen is made, at Sudbury, says, &c. (See SUDBURY) some bone lace near Eye, and at Lavenham some calimancoes. The principal exports are corn and malt. Woodbridge has a share of the coasting trade and makes some fine salt, and lime from fossil shells. Lowestoff and Southwold have a mackarel and herring fishery in which many vessels are engaged.

One of the principal objects of antiquity in Suffolk is the Roman castle of Burgh situated on an eminence near the confluence of the Yare and Waveney. It is supposed by Camden and others to be the *Garianonum* of the Romans, erected in the reign of Claudius by Scapula who conquered the Iceni. It forms three sides of a parallelogram with rounded angles. The north and south sides are each 321 feet long, and the east side 642 feet long; the walls are sixteen feet high and nine feet thick, enclosing five and a half acres, including the walls: The chief entrance was on the east side. There is a circular moat at the south-west corner. A little to the north are the remains of a monastery, built by an Irish monk. The monasteries of Bury St. Edmunds and Framlington, and several old churches are among the most remarkable of the Saxon antiquities.

The following was the population of the county in 1821:

Number of houses	42,773
Families	55,069
Families in trade	17,418
Total population	270,542

The population of the chief towns are as follows:—

Ipswich, burgh of,	17,186
Bury St. Edmunds, burgh of,	10,000
Woodbridge town and parish	4,060
Sudbury, burgh of,	3,950
Lowestoff town and parish	3,675
Beccles town and parish	3,473
Bungay town and two parishes	3,270
Mildenhall town and parish	2,974
Hadley town and parish	2,929
Framlington town and parish	2,327
Stowmarket town and parish	2,252
Halesworth town and parish	2,166
Eye burgh and parish	1,882

For farther information respecting this county, see the *Beauties of England and Wales*, Vol. xiv. Young's *Agriculture of Suffolk*, and Kirby's *Suffolk Traveller*.

SUFFOLK, county of, Massachusetts, containing only the townships of Boston and Chelsea. See BOSTON. Including the city of Boston, this county in 1820 contained 43,941 inhabitants; and in 1830, 62,162, or above 41½ per cent.

SUFFOLK, a county in the state of New York, comprising the eastern part of Long Island, bounded by Queen's county W.; Long Island sound N.; and the Atlantic Ocean northeast and east. Length from W. to E. 80 miles. The width varies from one to near eighteen miles, but is at a mean of about eight; area 640 square miles. Extending in lat. from 40° 25′ to 41° 25′ N.; and in long. from 3° 33′ to 5° 8′ E. from W. C. The general range of this part of Long Island is from NNE. to SSW., and composed of a ridge extending in a similar direction with the island, and a slope falling from the ridge towards the Atlantic Ocean. The ridge rises rather abruptly from Long Island Sound, to from one hundred to in some places three hundred feet elevation. The eastern declivity near the base of the ridge also falls rather rapidly, and thence slopes by a more gradual descent to the level of tide water. This plain is followed by a chain of shallow and narrow sounds, which are again succeeded by a series of low, long, and narrow sand islets. The sounds are from two or three miles to a quarter of a mile wide, and in no place admitting vessels of more than two or three feet draught. The eastern extremity of the island and county is broken into two long points, with an intervening intricate bay. The southern promontory is terminated by Mortaug Point, and the northern by Oyster Pond Point. The northern, and relatively to the continent, the interior peninsula is about 30 miles long, and is evidently a continuation of the central ridge, and is continued in Plumb Island, Gull Island, Fisher's Island, and Stonington Point, outside the bay of Pawcatuck. On the whole the surface of Suffolk county on Long island may be regarded as level. Soil rather sterile, and much of it wooded with pine timber. The climate is, however, more mild and agreeable than that of the continent opposite; and such are the other advantages of position, that as early as 1820 the distributive population was 38 to the square mile, nearly the whole county having an aggregate of 24,272.

Though along the Atlantic side of the island the depth of water and want of harbors is very unfavourable for shipping, that is not so much the case on the eastern and western sides. The gulf which penetrates between Mortaug and Oyster Pond points, called Gardner's to the eastward, and Peconic bay still farther down the island, affords, beside some of lesser note, the haven and town of Sagg Harbor. This is indeed a very prosperous port of entry, and had in 1820 about 150 dwelling houses, 6000 tons of shipping, two extensive rope walks, three salt works, and 1296 inhabitants. N. lat. 41°; long. 4° 38′ E. of W. C. By post road 108 miles a little N. of E. from the city of New York, and 26 miles a little W. of S. from New London in Connecticut. Beside Sagg Harbour, and Suffolk, the seat of justice, there are thirty other post offices in Suffolk county.

SUFFOLK, post town and seat of justice, Nansamond county, Virginia, situated on the right or eastern bank of Nansamond river, 28 miles SW. by W. from Norfolk, and by post road 224 miles a little E. of S. from W. C., and 102 miles SE. from Richmond. N. lat. 36° 42′; long. 0° 26′ E. of W. C. Vessels of considerable tonnage ascend Nansamond river to Suffolk. Population about 400. DARBY.

SUGAR, the name of a well known vegetable product, of the general and chemical nature of which we have given a pretty full account in our article CHEMISTRY, Vol. V. p. 747.

The art of refining sugar, however, which is not described in that article, and which has been brought in this country to great perfection, still remains to be considered.

In the common method of refining sugar, the ordinary Muscovado sugar is boiled with fresh bullocks' blood and lime water, and the scum or impurities produced by the successive additions of the bullocks' blood, is continually removed, till the sugar casts up only a clean milky froth, which indicates the removal of impurities. In order to heighten the whiteness, a little of the finest indigo is added. In this operation the heat of the fire is applied directly to the pan containing the sugar.

The next process is that of evaporating the pure saccharine solution: This is effected by a moderate fire, and the boiling is continued till the sugar has the proper degree of viscidity or ropiness, which is easily ascertained by what is called the proof stick.

When the evaporation is completed, the hot sugar liquor is removed out of the pans into coolers, and it is here gently stirred to prevent the formation of a crust. It is then granulated by an oar, the violent motion of which continued for several minutes, destroys the viscousness of the sugar, and completes the granulation. The beauty of the sugar depends on the perfection of this process.

The next step is to fill the moulds, which are earthen vessels like inverted cones, the apex of which is undermost. The clarified concentrated juice is then poured in by three different pourings. In order to prevent adhesion to the moulds, and to lay the grain of the mass even and regular throughout, the sugar is scraped from the sides of the cone by a wainscoat knife, the fluid is allowed to rest a few minutes till it has got some firmness. The moulds are then stirred round three or four times, and the process is finished.

The above is the process for single loaves, or sugar once refined. The double loaves, or those doubly refined, are made by a process in which the clarification is effected by the whites of about 200 eggs for each pan, and with fresh water in place of lime water.

The scums taken off during these processes are employed to yield an inferior sugar by methods of purification, which are not interesting to the general reader.

We had left the sugar in the conical moulds. These moulds are now placed above pots, and the stopper or rag at the bottom or apex of the moulds having been previously taken out, and a punch made with an awl, there will exude from this aperture a syrup or molasses, which in twenty-four hours will fill one half of the pot. This syrup is then removed, and the pot replaced under the apexes of the moulds. A small ladleful of wet clay is then poured on the face or base of each loaf or cone of sugar, which, after drying into a cake, in five or six days is removed and laid by for future use. On the day following the loaves are clayed a second time, and the cake when dry, is removed like the first. Each loaf is now drawn out of its mould, and irregularities and impurities brushed off. They are next left some days in the moulds to acquire hardness of surface. They are then turned out upon paper, freed from all little specks, and then dried on a stove for five, six, or seven days, when they are fit for sale.

In the preceding method of refining sugar, between twenty and thirty-five per cent. of molasses are found in the pots, and it is supposed that about two-thirds of this are produced by the intensity of the heat employed for concentrating the syrup. To remedy this evil various ingenious methods have been devised and successfully put in execution.

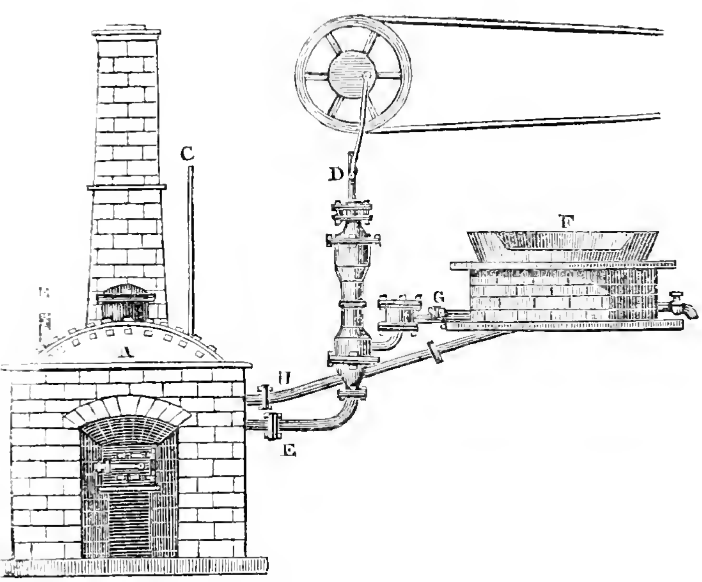
The first of these was invented by Edward Charles Howard, Esq. and was secured by patent in 1812. He brings the sugar liquor to a temperature of from 190° to 200° of Fahrenheit, by surrounding the pan with boiling water or steam, under the common pressure of the atmosphere.

A second method consists of covering the pan or boiler at top, and by creating a vacuum within the pan, to favour ebullition and rapid evaporation, at moderate heats. In these very ingenious processes Mr. Howard dispensed with the use of bullocks' blood, and he effected the clarification of the liquor by a system of ingenious canvas filters, assisted by a small quantity of pasty gypsum and alumina, formed by a saturated solution of alum in quick-lime. In the last purification, in place of covering the base of the sugar loaves with a stratum of wet clay, he covers them with a stratum of very fine saturated syrup.

In 1815, Messrs. P. and J. Martineau took out a patent for an improved method of refining sugar. It consists in employing animal charcoal, such as ivory black, bone ash or bone black, aluminous earths, ochres and lamp black. They prefer, however, the animal charcoal, and they use from two to five pounds of it for every cwt. of sugar to be refined. The usual finings of eggs, blood, or other albuminous matter, are used also in larger quantities than formerly, in order to combine the charcoal, &c. with the dirt in the sugar. The rest of the processes are the same as in common use; but the sugar thus produced has a high degree of purity and whiteness.

The most recent process for purifying sugar, and one which, from an accidental circumstance, has acquired great notoriety, is that of Mr. Daniel Wilson, who conceived the ingenious idea of boiling sugar by means of heated oil, passing through a worm or coil of copper pipe, fixed within the pan containing the sugar.

A view of this apparatus is annexed.



In the preceding elevation A is a wrought iron vessel for heating the oil, similar to the boiler of a steam engine. It is set in brick work, with a fire under it of a moderate size, and without any flues round the sides, so that the whole action of the fire is upon the bottom. It is made of an oblong form, and its length should exceed its breadth as much as the situation it is to be placed in will allow. The size depends upon the quantity of oil to be heated, or the liquor which is to be evaporated; and it is observable, that the more the surface presented to the fire exceeds the evaporating surface, the greater will be the economy of fuel. Whale oil, free from sediment, is found to answer better than any other for this purpose, and the quantity necessary to be employed is merely sufficient to cover the bottom of the vessel, to the depth of six or eight inches.

B is a thermometer for ascertaining the heat of the oil.

C is a small tube, opening at the lower end into the oil vessel, while the upper extremity passes into a long flue, called a steam vent, and communicating with the atmosphere. This pipe serves three different purposes: the first is, that before the pump begins to work in the morning, there is a quantity of air contained in it, and it is necessary there should be a vent for this when the pump is set to work, in order to prevent any compression in the inside of the vessel. The next is, that with a common suction-pump it is necessary there should be a communication with the atmosphere. Thirdly, it is designed to carry off the aqueous vapour from the fresh oil, which has a very bad smell, and such vapours would injure the sugars, if they got abroad in the sugar-house.

D is a cast iron pump, with a spring metallic piston communicating with the oil vessel A, by means of its suction-pipe E. It is set in motion in the usual manner, by some mechanical power.

F is a copper vessel, the bottom of which is covered in the inside by a coil or pipe, communicating at one of its ends with the pump at G, and at the other end with the oil vessel through the pipe H. Through this coil of pipe the heated oil circulates, and being surrounded on all sides by the liquid in the pan F, it gives out about 100° of heat in its passage, and returns to the oil vessel to obtain a fresh increase of temperature. This pan is surrounded by brick or wood work, to prevent cooling. Of course it has no fire under it.

This ingenious apparatus was erected in August 1819, by Messrs. Severn, King and Company, and one of the pans was wrought with great satisfaction and profit for nearly three months, when in Nov. 1819, a fire broke out and occasioned a loss of L. 80,000. On the ground that this new mode was more dangerous than the other one, the insurance offices refused to make good the above loss, and that celebrated trial took place in which half of the London chemists gave evidence the reverse of the other half. The point was decided against the insurance offices.

Mr. Wilson's process differed also in other respects from the common one. For every cwt. of sugar a solution of sulphate of zinc, in as small a quantity of water as possible, is added to the melted sugar in the pan. The oxide of zinc combines with the extractive matter, tannin and gallic acid, and renders them insoluble, while the sulphuric acid combined with the lime is insoluble also. When a strong grain is required, and the raw sugar contains much acid, a mixture of lime, consisting of an oz. of powdered lime in water is added about five minutes after the sulphate of zinc solution has been added. This method is used along with the patent filtering apparatus invented by Mr. J. Sutherland.

It is well known that sugar can be obtained from many vegetable substances, but particularly from the root of White Beet. In consequence of the destruction of the sugar plantations of St. Domingo, and the resolution of Bonaparte to exclude the colonial produce of Great Britain from the continent, he exerted all his means to supply the place of colonial produce by articles of indigenous growth. Chaptal, Dombasle and others, seconded his views; the Institute reported on the subject in 1800, 1810; and in 1812, the manufacture was extending rapidly. The events of the war put an end to such operations, but in 1819 they were again in considerable activity, and in 1825, there were 100 manufacturers who furnished altogether about 4 or 5 millions of lbs. of raw sugar (from 2000 to 2500 tons), which was not the twentieth part of the consumption of the kingdom.

The following table from M. Dubrunfaut shows the expense of growing the beet in ten different estates in France and Flanders, and the quantity produced in each for every hectare ($2\frac{1}{4}$ acres). The expense in the last column includes that of labour, &c

	No. of kilogrammes. Of Beet per hectare.		Expense of 500 kilogrammes.	
1	12,500	-	14 francs	56 centimes
2	30,000	-	9 —	20
3	25,000	-	7 —	50
4	30,000	-	6 —	65
5	25,000	-	8 —	40
6	16,390	-	9 —	—
7	16,500	-	8 —	66
8	18,000	-	7 —	95
9	26,625	-	6 —	25
10	37,500	-	10 —	—
Total,	237,515	Total,	88	5
Average,	23,751	Average,	8	80

According to our author about 4000 tons of roots (4,114,200 kilogrammes), cost £5600, or 136,082 francs, when manufactured into sugar.

The produce of this quantity of roots he estimates thus:—

As 70 per cent. of juice is extracted, this would leave 30 per cent. pulp, worth 15 francs per 1000 kilogrammes (12 francs per ton), or 18,514 francs.

Raw Sugar 4½ per cent. on the weight of the roots, or 185,139 kilogrammes, - - - - - - -	222,167
Molasses, 153,960 litres=201,600 kil. fit only for distillation, 10 francs per 100 kilogrammes, - - -	20,160
	260,841
Deduct cost above mentioned,	136,082
	124,759

and deducting for the expenses 135,082, and the sum of 38,674 francs, for the value of the pulp and pure molasses, we find a balance of 97,408, which, divided by the weight of the sugar, 185,138 kilogrammes, gives 58 centimes, per kilogramme, or 2½d. per lb. At the manufactory of M. Crespel, near Arras, the cost is 3½d. per lb.

Several very remarkable views and facts respecting the formation of sugar, have been lately brought to light. M. Kirchoff, a Russian chemist discovered that starch may be converted into sugar, by being boiled for some time in very dilute sulphuric acid. M. Theod. Saussure found that *one hundred* parts of starch yielded *one hundred and ten* parts of sugar, and he concluded that sugar is merely a compound of water and starch. Thus,

	STARCH.		SUGAR OF GRAPES.
Oxygen	55.87	- - - - -	56.51
Carbon	37.19	- - - - -	36.72
Hydrogen	6.84	- - - - -	6.78
	100.00		100.00

According to the analysis of M. Berzelius, starch and common sugar are thus composed:

		Starch.		Common Sugar.
Oxygen	-	49.6	- -	49.856
Carbon	-	43.5	- -	43.265
Hydrogen	-	7.0	- -	6.879
		100.0		100.000

Hence the abstraction of a little hydrogen and carbon would convert starch into sugar.

The most remarkable discovery, however, relative to sugar, is that made by M. Braconnot relative to the formation of sugar from the sawings of wood, old rags, and paper, of which a brief account will be found in our article SCIENCE, *Amusements in*, Vol. XVI. p. 610.

SULLIVAN, county of, New Hampshire, formed recently from the northern or upper towns of Cheshire county. Sullivan is bounded N. by Grafton; E. by Merrimac; SE. by Hillsborough; S. by Cheshire; and by Connecticut river separating it from Windham county, Vermont, SW.; and from Windsor county, Vermont, W. and NW. Length from S. to N. 32; mean width 18; and area 576 square miles. Extending in lat. from 43° 10′ to 43° 37′ N.; and in long. from 4° 30′ to 5° 5′ E. from W. C. This county lies entirely in the basin of Connecticut river, and has its declivity eastward from a range of hills separating the basins of Merrimac and Connecticut; and is drained by the sources of Ashmelot, and by Cold river, Sugar river, and some smaller streams. Surface very broken, but soil excellent for grasses of all kinds.

Beside Newport, the seat of justice, there are sixteen post-offices in Sullivan; the principal villages in which these offices exist are Charlestown, Claremont, Croyden, Goshen, Lempster, Plainfield, Springfield, Unity, and Washington.

Newport, the seat of justice, stands a small distance west of Sunapee lake, on Sugar river. N. lat. 43° 20′; long. 4° 52′ E. from W. C. by post road; 40 miles NW. by W. from Concord, and 467 miles NE. from W. C.

SULLIVAN, county of, New York, bounded by Delaware county of the same state, NW.; Ulster N. and NE.; Orange SE. and S.; and by Delaware river, separating it from Pike county of Pennsylvania, SW.; and from Wayne county of Pennsylvania, W. The longest line that can be drawn in this county is one very nearly due N. and S., from the southern angle at the mouth of Mongarep creek, to the most northern angle, 39 miles; and the area being within a small fraction of 819 square miles; the mean breadth is about 21 miles. Extending in lat. from 41° 26′ to 42° N.; and in long. from 1° 55′ to 2° 38′ E. from that meridian of Washington city.

The surface of this county is elevated, broken by hills, and in part mountainous, and nearly the whole drained by creeks flowing into Delaware river. The northern part has a western declivity, and gives source to Beaver Kill, a confluent of the Popachton branch of Delaware river. The central and southern part of the county declines southwardly, and is also drained into Delaware river by the Mongaret, Nevesink, and other creeks. By the levels taken on the Hudson and Delaware canal, the lowest part of Sullivan county must exceed 455 feet above the ocean level; and of consequence, from its mountainous aspect and position, the arable soil must lie between 500 and at least

1000 feet of such relative height. It is probable that the mean height of the farms exceeds 800 feet, or an equivalent to two degrees of Fahrenheit in the mean temperature of the climate. This difference is distinctly seen in the advance of spring and autumn in Sullivan, and in similar latitude on Hudson river.

The southeastern and lower part of Sullivan county has gained public importance and local advantage from affording a part of the route of Hudson and Delaware canal. This canal leaves the Delaware river at Carpenter's Point, at the mouth of Nevesink river, and in the western part of Orange county, and passes thence in a northeastern direction along the valleys of the Nevesink, Rondont, and Waalkill, to the Hudson at Eddyville, nearly opposite Rhinebeck, and passes by the villages of Essopus, or Kingston, Marbletown, Mombacus, Warwassing, &c. The rise from tide water in Hudson 535 feet, and fall from the summit level to Delaware river 80 feet.

By the post lists publishing at this time (May 1831), there are beside Monticello the seat of justice, post towns Bethel, Bloomingburgh, Cochecton, Fallsburgh, Forrestburgh, Grahamsville, Liberty, Nevesink, Philipsport, Rockland, Searsville, Thompsonville, West Brookville, White Lake, Woodbourne, and Warsborough. In 1820 the population amounted to 8900.

SULLIVAN, county of, East Tennessee, bounded by Carter's mountain separating it from Carter county, E. and SE.; by Washington county S.; Hawkins W.; Scott county of Virginia NW.; and Washington county of Virginia NE. This county lies in a near approach to a right angled triangle, longest side on Carter and Washington counties in the same state 45 miles; the perpendicular south from the Virginia line 18 miles, but a southern curve of the longest side increases the area to about 500 square miles. Extending in lat. from 36° 22′ to 36° 35′, and in long. from 4° 58′ to 5° 30′ W. from the meridian of Washington city. The entire declivity is to the southwest, and the far greatest part of the area included in the valley of the main branch of Holston river. This stream rising in Wythe county of Virginia traverses Washington county in that state, and entering Sullivan county in Tennessee, receives the Watanga from Carter county, and flowing a few miles farther to the SW. curves abruptly to NW., and receives the north branch on the boundary between Holston and Hawkins counties. The surface is elevated and mountainous, but with much good soil. In the post list of 1831 there are enumerated in Sullivan county, Tennessee, five post towns, beside Blounsville, the county seat; these are Hilton, Kingsport, Pactolus, Paperville, and Rockhold's Store. The population in 1820 amounted to 7015.

SULLIVAN, county of, Indiana, bounded by Vigo county in the same state, N.; Clay NE.; Greene E. and SE.; and Wabash river, separating it from Crawford county of Illinois SW., and Clark county, of Illinois NW. Length from S. to N. 28, mean width 20, and area 560 square miles. Extending in lat. from 38° 53′ to 39° 17′, and in long. from 10° 16′ to 11° 42′ W. from W. C. The slope is to the southwestward obliquely towards Wabash river. Surface moderately hilly, and soil excellent. In the beginning of 1831 there were but three post offices in this county; these were situated at Merom, the seat of justice, Carlisle, and Yurman's creek. Population in 1820, 3498. DARBY.

SULLY, MAXIMILIAN BELLEVUE, Duke of, was born at Rosni in 1559, and was descended from an illustrious Protestant family of the counts of Flanders. At the age of eleven, when he was in Paris, he escaped from the massacre of St. Bartholomew in 1572, by being concealed for three days. The leading events of his public life and his character will be found in our article FRANCE, Vol. IX. p. 301—307. He died in 1641, at the age of 82. The *Œconomies Royales*, or the Memoirs of Sully, written by himself, are much esteemed for the simplicity of the style, and the interesting anecdotes they contain.

SUMACH. See FRANCE, Vol. IX. p. 414.

[SUMASINTA, river of the republic of Mexico, as laid down on Tanner's Mexico, rises in the mountains of Guatemala, N. lat. 15°, and 15° W. long. from W. C.; and in the extreme southern part of Chiapa; flows thence northwardly, first separating Yucatan from Chiapa, and then from Tabasco, is finally lost in the Gulf Terminos, after a comparative course of about 220 miles. The gulf or bay at the mouth is shallow, admitting only small vessels.] DARBY.

SUMATRA, a large island in the Eastern Sea, and the most westerly of the Sunda Islands. It extends about six degrees on each side of the equator, and is about 1050 miles long, and 165 broad. A chain of mountains in double and treble ranges, extends through the island. Mount Ophir, under the equator, rises 13,842 feet, but snow has never been seen on its summit; or on that of any of the rest. Between the ridges of these mountains there are extensive plains of great elevation, where the inhabitants principally reside on spots cleared of the woods which clothe every part of the island. These plains abound with large lakes, from which issue rivers and streams, the largest of which is the Siak, the Indragiri, the Jambi, and the Palembang, flow to the eastern coast, while the small ones in great number discharge themselves into the western sea. The most important of these are the Kataun, the Indrapura, the Tabuyong, and the Sinkel.

The mean temperature of Sumatra is, we are persuaded, not above 81°, the average measure of the equatorial heat. According to Mr. Marsden, the thermometer fluctuates between 82° and 85° in the most sultry heats. At Fort Marlborough, he never saw it higher than 86° in the shade; though at Natal, in north lat. 0° 34′, it is not unfrequently at 87° and 88°. Now, at sunrise, it is usually as low as 70°; so that 81° will be found a full measure of the average mean temperature. Beyond the first range of hills the people light fires in the mornings. The southeast monsoon, or dry season, is between May and September inclusive, and the northwest monsoon begins about November; and the hard rains cease in March. There are a number of volcanic mountains; and earthquakes frequently occur. Thunder and lightning are also frequent.

The soil of Sumatra is generally a reddish stiff clay, burned nearly to a state of brick with the sun, but covered with a stratum of black mould. The principal article of produce is rice of various kinds, which, in some cases, gives a return of 140 for 1, though in general it is only 30 for 1. The cocoa nut, the sago tree, the sugar cane, are also cultivated, but very little sugar is made. Maize, chilly pepper, turmeric, ginger, coriander and cumin seed, are reared in gardens. Hemp is cultivated in order to obtain bang, which is smoked in pipes along with tobacco, which is also cultivated.

The principal fruits of Sumatra are the mangosteen, the pine apple, oranges, the white and red shaddock, limes and lemons, the bread fruit, the jack fruit, the mango, the papaw, the pomegranate, the tamarind, nuts and almonds, wild grapes. Among the medicinal and useful trees may be enumerated the castor-oil plant, the caoutchouc tree, the camphor tree, the coffee tree, the indigo tree, and the upas tree, which is not injurious to those who come near it.

Sumatra is rich in mineral productions. There are mines of copper, iron, and tin. Sulphur and nitre are also plentiful. Yellow arsenic is also found. Coal, washed down by the floods, is procured in many parts. There are mineral and hot springs, and springs of petroleum. Yellow, red, and white ochres, are abundant.

Gold, which is found chiefly in the interior, occurs imbedded in the rock, forming veins in quartz. The mines are generally at the foot of the mountains, and are wrought by horizontal shafts from 50 to 150 feet long. The gold is also found in smooth masses like gravel, one of which seen by Marsden weighed 9 oz. 15 grains. There are no fewer than 1200 gold mines in the dominions of Menancabow. It is said that 11,000 ounces have been annually received at Padang, 2000 at Nalaboo, 800 at Natal, and 600 at Mocomoco.

Among the articles exported from Sumatra may be enumerated the edible birds nest, the Biche de Mer, bees wax, gum Lac, ivory, pepper, cassia, aloes, gum dammer, benzoin, camphor, dragons' blood, salted roes. The imports are, from Coromandel, cotton goods, blue and white long cloth, chintz and coloured handkerchiefs, and salt; from Bengal, muslins, cotton goods, taffetas and opium; from Malabar, coarse cottons; from China, porcelain, iron-pans, tobacco, gold thread, &c.; from Celebes, the rough striped cotton which forms the dress of the natives, krises, hats, small pieces of brass ordnance, spices; and from Europe, silver, iron, steel, lead, cutlery, hardware, brass wire, and broad cloth, particularly scarlet.

The inhabitants of Sumatra have made but little progress in the useful arts. Fire arms, nails, adzes, axes, hoes are made in different parts. They are good carvers in wood and ivory; they make good cane and basket work. Silk and cotton cloths, gold and silver embroidery, earthenware, gunpowder, salt, gold and silver filagree work, are the chief objects of their industry.

The *doosoons*, or villages, are generally situated upon an eminence, on the banks of a river or a lake The houses form a quadrangle, with lanes between. The balii or town-hall stands in the centre of the square. It is a room from ninety to a hundred feet long, and from twenty to thirty feet wide, and open at the sides, unless when it is hung with mats or chintz. The houses consist of a wooden frame, lashed with split bamboos, and generally roofed with the leaf of the Neepal's palm. To secure themselves from wild beasts, the inhabitants raise their houses to different elevations, and they ascend to them by a piece of timber or stout bamboo cut in notches. The better class of houses are ornamented externally with uncouth carved ornaments: they have neither tables nor chairs, nor knives or forks. In cooking they employ an iron vessel.

Sumatra is chiefly occupied by the empire of Menancabow, and the Malays; by that of the Acheenese; the Battas, the Rejangs, and that of Lampong. The Malay language is universally spoken along the coast. It prevails also in the inland territory of Menancabow, and is understood almost throughout the island. Their written character is the Arabic. Many other languages prevail in the island, but of these the Rejang and the Batta are the chief.

Sumatra abounds with wild animals, the tiger, the elephant, the hippopotamus, the rhinoceros, the bear, deer of various kinds, sloths, squirrels, monkeys, the gigantic orang-outang,* civet-cats, tiger-cats, porcupines, hedgehogs, alligators, boa-constrictors, guanas, chameleons, flying lizards, tortoises, and turtle. Among the domestic animals are the buffalo, which affords milk, beef and broth, the cow, the horse, the sheep, the goat, the hog, the otter, the cat, the dog and the rat. Among the birds are the beautiful Sumatra pheasant, eagles, vultures, peacocks, kites, crows, &c. The island swarms with insects.

For farther information respecting this island, see *Beschreibung der insel Sumatra*, besonders in *Ansehung des Handels*, &c. von Adolph. Eschelskron, Hamb. 1781. Marsden's *History of Sumatra*, Lond. 1783. Shelbeare's *History of Sumatra*, Lond. 1787. Van Schirak's *Description of the Commerce of Sumatra*, in Dutch, Harlen, 1789: and the *Asiatic Researches*, vol. x. See also our article Acheen.

SUMNER, one of the northern counties of Ten-

* See Dr. Brewster's *Journal of Science*, No. VIII. p. 193. No. XIII. p. 162. No. XVII. p. 1. and *New Series*, No. II

nessee, bounded by Smith county in the same state E.; by Cumberland river separating it from Wilson county S.; by Manpoes creek separating it from Davidson SW.; by Robertson county NW.; and by Simpson and Allen counties in Kentucky N. This county reaches in lat. from 36° 12′ to 36° 37′; and in long. from 9° 8′ to 9° 42′ W. from W. C. The separating summit level between the vallies of Cumberland and Greene rivers traverses Sumner from E. to W., dividing it into two inclined planes. The northern and least extensive slopes to the NNW., and gives source to creeks flowing into Big Beaver branch of Green river. The largest or more extensive declivity falls southwardly, and is drained by creeks falling into Cumberland river. Surface waving rather than hilly, with an excellent soil. In the beginning of 1831 there were post offices in Sumner, at Bracken's, Cairo, Fountain Head, Gallatin, Green Garden, Hartsville, Hendersonville, Long Hollow, Montgomery, and Tyree Springs.

Gallatin, the seat of justice, is situated near the middle of the county, from east to west; but, towards the southern border, on Cumberland river, 27 miles NE. from Nashville, and as stated in the recent post office list, 699 miles from Washington city.

Cairo is on Cumberland river, five miles a little E. of S. from Gallatin. Hartsville is also situated on Cumberland river, in the extreme southeastern angle of the county, and by post road 41 miles above, and NE. by E. from Nashville.

This county is in length from east to west 38; mean width 17; and area 646 square miles.

SUMPTER, district of, South Carolina; bounded NW, by Kershaw; NE. by Lynches river separating it from Darlington; E. and SE. by Williamsburg; S. by Santee river separating it from Charleston district; SW. by Santee separating it from Orangeburg; and W. by Wateree separating it from Richland. Greatest length from the extreme southern part on Santee river to the extreme northern on Lynch's creek, 62 miles; mean width 20; and area 1240 square miles. Extending in lat. from 33° 23′ to 34° 17′, and in long. from 2° 51′ to 3° 38′ W. from Washington city. General declivity SSE. It is bounded on two sides by navigable rivers, whilst the central parts are drained by Black river, branch of Winyaw.

Sumpterville, the seat of justice, stands on a small branch of Black river, near the centre of the district, 93 miles a little W. of N. from Charleston; 44 miles a little S. of E. from Columbia; and by post road 481 miles SSW. from the city of Washington. N. lat. 33° 53′, long. 3° 22′ W. from W. C.

Beside at Sumpterville, there are post offices in this district at Bishopville, Bradford Springs, Bradleyville, Friendship, Fulton, Jacksonville, Jamesville, Manchester, Mill Grove, Mount Clio, Salem, Statesburg, and Willow Grove.

In 1790 Sumpter contained a population of 6940; in 1800, 13,103; in 1810 it contained 19,054; and in 1820, 25,369. For the population in 1830 see the general table of the counties under the head of United States.

SUNBURY, post town, borough, and seat of justice, Northumberland county, Pennsylvania, situated on the left bank of Susquehanna river, on the point immediately above the mouth of Shamokin creek, two miles below the junction of the two main branches of Susquehanna river, and a similar distance below the borough of Northumberland, with the breadth of the east branch superadded; 52 miles above and N. from Harrisburg, and by post road 162 miles a very little E. of N. from Washington city.

From Philadelphia there are two roads to Sunbury. The most direct is by Reading and Orwigsburg, 123 miles; the second by Lancaster and Harrisburg, 148 miles. Population about 1000.

SUNBURY, post town and sea port, Liberty county, Georgia, situated at the head of St. Catharine's sound, and mouth of the small river Medway, 10 miles E. from Riceborough, the county seat; 34 miles SSW. from Savannah; and by post road 212 miles a little S. of SE. by E. from Milledgeville. Lat. 31° 45′ N. Long. 4° 22′ W. from W. C.

The harbour is open to the sound, distant about eight miles from the Atlantic ocean; but the northern projection of St. Catharines island contributes to shelter vessels from southern and south-eastern winds. DARBY.

SUN. See ASTRONOMY, *Index*.

SUNDERLAND, a borough and sea-port town of England, in the county of Durham, is situated on the southwest bank of the Wear. It is united to Monk Wearmouth by the celebrated iron bridge, of which we have already given a full description and drawing, (see BRIDGE, Vol. IV., p. 479, and Plates XCI. and XCIII.) so as to form altogether a town about one and a half mile long, and one mile broad. It consists of one principal street, called the High Street, formed by the road to Durham, which contains many handsome houses. Several of the other streets, which branch off from it, are narrow and dirty. Lately, however, great improvements have been made in widening, lighting and repairing the streets. The church is large and handsome, having a light and elegant east front. A spacious and elegant chapel of ease was erected in 1767, and there are also excellent places of worship for the Presbyterians, Independents, Baptists, Quakers, Methodists and Unitarians. The Methodist chapel is a handsome building, which holds 1500 persons. The other public buildings and institutions are the exchange, a handsome edifice, a theatre, assembly room, an excellent subscription library, a dispensary, a humane society, a charity for decayed seamen and their widows, a girls' school, a blue-coat school, besides two charity-schools, one on Lancaster's plan, and the other on Bell's plan, at Bishops Wearmouth. On the moor to the east of the town, are commodious barracks capable of accommodating 1800 men.

The harbour is inclosed by two piers, one on each side of the river. The south pier is old, but the north one has been erected since 1788, and gives great security to the shipping. The tide now flows sixteen feet, and admits vessels of 300 and 400 tons burthen. An elegant circular lighthouse has been erected near the end of the northern pier.

The trade of Sunderland has been long progressively increasing. The principal imports are corn, flour, wines, spirituous liquors, timber, tar, deals, flax, iron, &c. The exports are coal, lime, glass, glass bottles, grindstones and copperas. The coal trade employs about 500 vessels, besides 492 *keels*, or flat-bottomed craft; which convey the coal from the staiths to the ships. The coal is chiefly sent to London, but also to the Baltic, France, Holland, &c. The quantity annually exported was reckoned at 315,000 Newcastle chaldrons; but in 1820 it amounted to 421,061 chaldrons. The persons employed in the coal trade on the river Wear only amounted to 26,000. The lime is sent chiefly to the coasts of Scotland and Yorkshire.

The principal manufactures here are those of cordage, bottles, flint glass, broad glass, white and brown earthenware and copperas, tar, &c. Shipbuilding is carried on to a great extent. In 1814, 8000 vessels cleared out of Sunderland harbour. The town is governed by a vestry or association of the inhabitants, having freehold estates, at the annual value of £10. They continue in office three years. A little to the south of Sunderland, on the edge of the sea, is a chalybeate spring, nearly as strong as that of Harrowgate. The following was the population of the town in 1821:

Houses	1,618
Families	4,064
Do. in Trade	949
Total population	14,725

See the *Beauties of England*, vol. v. p. 135.

SUPERIOR, LAKE. See CANADA, Vol. V. p. 233.

This greatest sheet of fresh water on the earth is itself a reservoir for a circular band of territory around it varying in width from 40 to 80 miles, and measured at about mid-distance from the lake equals in length 15 degrees of a great circle, equal to 1042 statute miles. Including the whole valley, or the lake and land surface drained into it, we find a physical section in the form of a vast triangle; base from east to west passing through St. Mary's strait to the height of ground between St. Louis and Rum rivers 500 miles. Perpendicular 350 miles. These elements give an area of 87.500 square miles. Of this expanse, lake Superior itself occupies a triangular surface; base 350 miles from the outlet of St Mary's river to the mouth of St Louis's river 350 miles. Greatest width 160 miles, but mean width about 86 miles as the area is by careful admeasurement on numerous maps, within a small fraction of 30,000 square miles. The valley of Superior lies, according to Tanner's United States, and his North America between N. lat. 46° and 51°, and between Long. 7° and 17° W. from the meridian of Washington city.

The present is a favourable opportunity to correct a prevalent error. Lake Superior has been called the American Caspian, and very frequently stated to be equal or even more extensive than the Caspian. But these comparisons are very erroneous; the Caspian is 690 miles from south to north, and the mean width at least 180 miles, giving an area of 124,200 square miles; or upwards of four fold more extensive than is lake Superior. In reality the whole five great lakes of Canada, and all the intermediate land taken together, but little exceeds the surface of the Caspian; and the actual water surface of the five Canadian lakes is to that of the Caspian as one to three very nearly.

The surface of lake Superior is elevated above the Atlantic tides 641 feet, but the utmost depth sinks below the ocean level, and of course if a strait level with the ocean connected it with the lake, the latter would still exist as an inland sea.

The immense depth of the Canadian lakes, except Erie, is indeed amongst the most extraordinary facts in their natural history. Lake Superior is perhaps the deepest of the three higher lakes, but each admits the navigation of the largest vessels. Similar to the Caspian, the lakes of Canada have shores very deficient in harbours; and lake Superior in particular has immense walls of rock stretching along much of its border.

The enormous mass of water from Superior passes over what has been very erroneously called the falls of St. Mary, but which is in reality not a very steep cataract, and is passable with boats. The entire fall determined by general Gratiot is 22 feet 10 inches. The strait of St. Mary if measured from the lower end of St. Joseph's island into the open water of lake Superior, is about seventy miles in direct length. The real narrows at the cataract, where Fort Brady now stands, is at N. lat. 46° 31'. Long. 7° 18' W. from the meridian of Washington city.

From the geographical position and the long and intense frosts so near the eastern side of a large continent, the upper lakes of Canada would be annually frozen in winter, if that phenomenon was not prevented by their prodigious depth. Their bays and rivers are annually frozen, in fact; but the great mass and depth of the open lakes prevent the formation of solid, compact, and passable fields of ice. DARBY.

SURAT, a large city of Hindostan, in the province of Guzerat, situated in a fertile plain on the south bank of the Tappi or Taptee. It is defended on one side by the river, and elsewhere by a brick rampart about twenty feet high, and a ditch, having a strong citadel, with an esplanade. The squares of Surat are spacious, but the streets are generally narrow, irregular and unpaved. Every street has its own gates, which are shut in cases of alarm. The citadel, which is the principal building, is a large quadrangular building, of hewn stone, with a circular and spacious bastion at each angle, mounted with three tiers of guns, the lowest being 36 pounders, the second 24, and the upper 18 and 12 pounders. In all, there are 200 cannon mounted, besides 24 at the saluting battery. The houses for the officers are elegant. The durban palace is about two hundred paces distant. The mint is a large pile of building, encircled with a lofty wall. There are two caravanserahs in Surat, and numerous bazaars or market places. Some of its mosques are handsome. There are here some fine water tanks.

As the Hindoos never willingly deprive any thing of life, they have here a large hospital for maimed or diseased animals, with an annual revenue of 6000 rupees, and occupying an extent of twenty-five acres. It is full of decrepid cows, sheep, rabbits, hens, pigeons, &c. who are attended by a physician. Niebuhr saw here a blind tortoise, said to be 125 years old.

The trade of Surat, once very great, has declined rapidly, both from the badness of its harbour, and the rise of Bombay. The river is full of sandbanks, and all large vessels are obliged to remain at its mouth, called Swallow roads, where there is good anchorage, but no shelter. Nearly two-thirds of the distance between the anchorage and the town, a distance of nearly twenty miles, is a continued chain of banks, with narrow channels between them. In the burial places of the Europeans in the suburbs, are many large and handsome tombs, worthy of being visited. Shipbuilding used to be carried on to a considerable extent, but much of it has been transferred to Bombay and Damaun.

From 1794 to 1796 the trade of Surat amounted annually to about 600,000 rupees, half of it being carried on with the Arabian, and half with the Persian gulf. In the year 1811 and 1812, the total imports amounted to 4,881,410 rupees, and the total exports to 3,966,523 rupees. This trade was carried on by fifty-seven vessels, whose tonnage amounted to 5318.

In 1796 the population of Surat was estimated at 800,000 souls, and by others at 600,000. It has been stated also at 400,000, and lately so low as 70,000, composed of persons of all nations and religions. East long. 73° 3′ north lat. 21° 13′. See Milburn's *Oriental Commerce*, vol. i. Hamilton's *East India Gazeteer*, and our article India, *passim.*

SURDS. See Algebra, Vol. I. p. 423 425.

SURGERY.

Surgery is that branch of the medical profession wherein manual operations form part of the occupation of the practitioner, and during certain periods of its history constituted the exclusive department of the individual who professed it; being derived from χειρ, a hand, and εργον, a work, whence it was termed chirurgery. This, however, will be better understood after we have detailed the history of surgery from the earliest ages.

History of Surgery.

Although there cannot be a shadow of doubt that surgery was coeval, if not prior to medicine, yet there is no account of any surgical operations before the siege of Troy, when that eventful strife immortalized in song the chirurgical deeds of Podalirius and Machaon, the godlike sons of Æsculapius, together with those of Patroclus, for in that memorable war, princes were as much renowned for their exploits in surgery as for those in battle.

Æsculapius lived about the beginning of the Trojan war, and was instructed in medicine and surgery by Apollo, and Chiron the Thessalian, named also the centaur. According to Diodorus Siculus, he was the inventor of medicine and surgery, which were in great repute during the Trojan war; and he carried botany to perfection as well as the use of medicines and operative surgery; at the dawn of medicine, all the departments of the medical profession were prastised by one individual, and that person frequently either a prince or a deified king.

It is supposed that the temples dedicated to Æsculapius were chiefly for his skill in surgery; and Podalirius and Machaon according to Celsus, confined themselves to the chirurgical part of physic, being the most ancient branch, as medicine, in the era of Æsculapius, 1263, before Christ, was chiefly practised by consulting the oracle at Pergamus. When we consider the restless spirit of man in the earliest ages, it is presumptive that wounds, fractures, and luxations must have existed from the creation, and that consequently many surgical remedies would originate nearly at the same period with man, for surgery and medicine must have been coeval with injuries and diseases inflicted on the human frame.

From the fall of Troy until the Peloponesian war, an interval of 700 years, and 431 before the Christian era, we have no accurate account of surgery; it is only known that the Asclepiades, descendants of Æsculapius, exercised the art. The great Hippocrates, also a lineal descendant of Æsculapius, appeared at that time, and has handed down to us works not less celebrated in surgery than in medicine. His writings, however, are more devoted to medicine than to surgery, having only composed chapters on fractures, diseases of the joints, ulcers, fistulas, hemorrhoids, wounds of the head and midwifery, the genuineness of some of which are questioned by his commentators; indeed, if we believe the singular oath which he administered to his pupils, he despised operative surgery, for in that extraordinary document he ordains, that "cutting for the stone I will not meddle with, but will leave to the operators in that way. He however used the lancet, the scarificator, the actual cautery, and the crotchet, and practised as a physician, a surgeon, an accoucheur, an apothecary and even a nurse. He is also exceedingly bold in his directions to "operators in that way," for in calculus of the kidney he thus observes, "when however there is tumefaction in the region of the kidney, an incision ought to be made, and the calculus carefully extracted; for if this operation be not performed, there are no hopes of a cure, and the disease will prove fatal." The reason, says Meibomius, why Hippocrates would not allow physicians to treat calculus in the bladder, was simply because it was too difficult.

The surgery of Hippocrates has, to the misery of the sufferers, been implicitly followed by nearly all succeeding authors; for as the great Bacon observes, authors have written, not that their works should stand as consuls, to give advice, but as dictators; and as John Bell justly states, "most unfortunately for science, Hippocrates wrote with such truth and brevity, with so sound and discerning a spirit of observation, and recited so carefully the signs of danger in all kinds of wounds and injuries, that he has been held in continual reverence, and holds an influence over the profession even to the present hour." His directions for the treatment of fractures are very unscientific, and even cruel, when we consider his extension and machines; his treatment of injuries of the head may be said to be both inert and cruel, inert as regards active blood-letting, and cruel in trephining for every fissure or crack of the skull.

In Egypt, according to Herodotus, lib. ii. c. 129, surgeons were divided, as in the present day, into oculists, capitists, dentists, &c.; and in Persia, A. M. 3483, according to the same historian, the surgeons of Egypt were held in high reputation. Democedes is mentioned as having become the principal favourite of Darius, of being loaded with honours and riches, merely for having succeeded in reducing one of his ankle-joints which was dislocated. Xenophon states, that Cyrus had an excellently appointed medical staff to his armies. In Egypt and Babylon, according to Herodotus and Strabo, the sick were exposed on the roads, in order that those passengers who had been similarly affected might give them their advice. The Egyptians considered the god Hermes the inventor of physic. About 500 years before the Christian era, the celebrated medical school of Alexandria flourished, at which Herophilus and Erasistratus had the boldness to introduce the study of human anatomy, the source of all its renown; but in consequence of the destruction of the Alexandrian library, we possess few of the writings of these great men; they were founders of particular sects; and Galen and Cœlius Aurelianus have collected all the scattered remains of their works, together with those of the other successors of Hippocrates, down to Celsus, a period of four centuries. It is presumptive that surgery was far advanced in perfection during the zenith of the Alexandrian school, when we consider the advantages then derived from a knowledge of dissection, and the many opportunities of practice which must have occurred in the celebrated campaigns of Alexander and his successors.

In Greece, during the time of Herophilus, there were dietetic, pharmaceutic, and surgical practitioners; the surgeon was restricted to the use of the knife, and was not permitted even to treat wounds, ulcers, or tumours. In this age also reigned the famous sects of empirics, dogmatists, methodists, &c.

Arcagathus, a Greek, was the first who practised surgery at Rome, U. C. 535, but he operated so frequently and rashly, and it may be presumed unscientifically, as he received the opprobrious appellation of hangman. Celsus, who lived during the reigns of Augustus and Tiberius, about the beginning of the Christian era, greatly advanced both medicine and surgery, and condensed all that was then known in one small volume; he has the merit of being the inventor of the ligature on wounded arteries, of union by the first intention or adhesive inflammation, of amputation in gangrene from external causes, of a scientific mode of performing amputation, of the operation of couching for cataract, and of performing lithotomy on the gripe, now termed the Celsian mode or operation, operations of the utmost importance in surgery, and improvements in operative surgery of the most vital consequence. It appears doubtful, however, whether Celsus really is entitled to the merit of being the inventor or discoverer of these important facts and operations, for he describes them not as his own invention, but as the practice of the day. Thus, under lithotomy he observes, "multi hic quoque scalpello usi sunt." We entertain the same opinion with Richerand concerning these ancient authors; thus, with regard to Hippocrates, he says, "Hippocrate n'est point le pere de la medicine, elle est la fille du temps et de l'experience. Ses ouvrages doivent étre regardés comme une sorte d'encyclopedie medicale." Celsus talks of Philoxenus, Gorgias, Sostratus, the two Herons, the two Apollonii, and Ammonius Alexandrinus of Egypt, having made discoveries in surgery; and of Tryphonius, Euelpistus, and Meges having made considerable additions to this art. It has been questioned whether Celsus practised as a physician and surgeon, but of this there can be no doubt, after an attentive perusal of his writings; no one who had not practised surgery could describe the operation and treatment of lithotomy as he has done; besides, he occasionally employs the first person singular. His qualifications for an operator are, "that he must be young or middle aged, have a strong and steady hand, never subject to tremble; to be ambidexter, to have a quick and clear sight, to be bold; and so far void of pity, that he may have only in view the cure of him whom he has taken in hand, and not in compassion to cries, either make more haste than the case requires, or make his cut less than is necessary, but to do all as if he was not moved by the shrieks of his patient." There is much truth in this sentence, but Celsus does not appear to be aware, that the greater part of these can be acquired, as was the case with Cheselden, who had a natural repugnance to operations; and hence also we presume does Richerand consider the firmness of mind requisite for a surgeon to be a gift of nature. Haller also confesses he could never summon up resolution or fortitude to operate. Bichat considered two things essential to form a great surgeon, genius and experience; and in his eulogium upon Desault, he thus observes, "La nécessité de l'anatomie en avoit fait naitre le goût. Son étude précède celle de notre art, ses vérités ajoutent à l'intelligence des siennes: et telle est depuis un siècle l'opinion publique, qu'elle ne sourit aux efforts du chirurgien, qu' apres avoir couronné ceux de l'anatomiste. Fabrice honora le théâtre de Padua, avant de s'immortaliser par ses œuvres chirurgicales. La science longuement méditée de nos organes, traça au lithotome de Raw et de Chesselden, la route methodique qu'ils semèrent de tant de succès. Petit, Hunter, furent applaudis dans leurs amphithéâtres, avant de briller sur la scène éspineuse de la pratique; et dans ces premières pages consacrées aux premiers travaux de Desault, je n' aurai à retracer que ceux qui firent sa reputation en anatomie." Our own opinion is, that daily dissection of the dead, combined with occasional operations on the living, is alone required for a scientific and dexterous operator; for, as John Bell observes, what are our great operations, but careful dissections on the living body. It is the habit of dissecting, with address, that fits a man for operating. An operator should be in the meridian of life, and ought to have begun his career early, both as a dissector and an operator, and must continue daily to prosecute dissection, that he may be familiarized with every part of the human body on every emergency.

Galen was the last author of distinction that practised physic and surgery at Rome, A.D. 160; he was educated at the Alexandrian school, and would have done deeds of wonder, had dissection been permitted in Rome, but being confined to the anatomy of monkeys, and the other lower animals, he was only able to add to the surgery of his day, a Treatise on Bandages; his works upon Anatomy rank high. He has entered more minutely into the different species of ruptures than his predecessors, but throughout his writings he is a contemptible dictator.

The compilation of Oribasius, who lived about the end of the fourth century, may be passed over in silence in its relation to surgery, but not so that of Ætius of Amida, who studied at the Alexandrian school, A.D. 500, in which are many observations on surgical operations, and some on the effects of the Guinea worm.

Paulus Ægineta, who lived in 640, and practised at Alexandria and Rome, wrote an excellent work on Surgery, containing all the improvements of his day; he invented some operations, of which tracheotomy was one, and improved others, particularly lithotomy. He also improved the doctrine of, and operation for aneurism, and is the first who treats of fracture of the patella; he was bold and decisive in his practice, opening the temporal or occipital artery, or external jugular vein in affections of the eyes or head, and relieving strangulated hernia by an operation.

Nothing but a chaos presents itself from this period to the beginning of the tenth century. Torrents of northern barbarians inundated the Roman empire, and swept man and civilization from the fairest provinces of Europe; and, almost in immediate succession, the hosts of Saracens, under Amrou, viceroy of Egypt, set fire to the noblest monument of antiquity, the Alexandrian library. Thus nearly three centuries were buried in oblivion, with respect to the sciences, literature, and the arts; while war, and all its attendant horrors, raged from the Euxine to the Atlantic.

The Arabians, at last contented with their conquests, requested, in 820, the Greek Emperor at Constantinople, to give them some of their best literary and scientific works; among those sent were Galen's, translated into the Syrian language, in which astrology and superstition were mingled with medicine. In the works of Rhazes, Halyabbas, and Avicenna, we have no facts or remarks concerning surgery, which are not to be found in Galen, excepting those relating to spina ventosa.

Avenzoar wrote on surgery, but apologizes for condescending to write on a subject so contemptible, for in his days, surgery was practised in Arabia by the servants of the physicians, while all operations on the female sex were performed by women.

Albucasis ranks highest of the Arabian surgeons; he has given a long list of surgical operations, and an equally formidable catalogue of instruments and machines, fit to terrify the operator himself, much more the patient. At this period they plunged amputated stumps into boiling pitch. In an Arabian work, by Abi Osbia, we have a catalogue of 300 medical writers, who have justly merited oblivion, being mutilated translations of the Greeks, adulterated with the magic and astrological fables of the Arabians.

In consequence of the tyranny and aristocratic despotism which reigned over Europe, the sciences, literature, and the arts remained in obscurity, and even in Greece, theological controversies absorbed all other kinds of literature or science until the middle of the fifteenth century, when they again began slowly to revive. The revival of literature and science is probably solely to be attributed to the crusades. In England, it was actually near the end of the fifteenth century before medicine was cultivated at Oxford as a regular science, and even at the medical schools on the Continent, the diploma of surgery was conferred after one year's study of anatomy. At the famous school of Salernum, where this law existed, and where there was compiled a system of medicine, entitled "Schola Salernitana," only one chapter is devoted to surgery, and that on fistulas. The degrees of bachelor and doctor had no doubt been conferred at Paris during the reign of Charlemagne, in 1231, but generally on the clergy and monks, who practised physic at this epoch, and who were, in consequence of the barbarous anathema pronounced by the Council of Tours, in 1163, prohibited from performing any surgical operations; in consequence of this, surgery was again formally separated from medicine, and practised only by the most illiterate of the laity. The *Ecclesia Abhorret à Sanguine* continued long a satisfactory cloak for preventing the study either of anatomy or the practice of surgery. Gilbertus Anglicus is the first who wrote on surgery in England, which was about the year 1300; he copied chiefly Rhazes. Bernardus Gordon, a native of Scotland, and John of Arden, are said to have flourished at this period; the latter wrote a work, entitled the Chirurgery. From the 11th to the middle of the 15th century, numerous works were published, but all mere compilations, or extracts from Arabian authors; from this mass we ought to except a treatise on Surgery, written by Guido de Cauliaco, or Guy de Chauliac, professor at Montpelier, who lived at Avignon in 1363, which continued for many years the sole classical work in France. For from this period until the day of the great Paré, surgery was degraded to the lowest possible degree. Paré, in his first editions of his works, styles himself 'Barbier chirurgien.' There were then bitter civil wars carried on between the clerical physicians and these unfortunate barber surgeons. Vidus Vidius, however, published a splendid Latin edition of Greek surgery in 1544. The great Paré, enlightened by the labours of Vesalius, Fallopius, and Eustachius, gave birth to an able work on surgery, founded on anatomy, in 1585, which had been previously published in separate treatises. He has been considered by some the inventor of the ligature on wounded arteries, but as that merit clearly belonged to Celsus, he must be viewed merely as the reviver of that important surgical means of stopping hemorrhage; for in the dark ages the ligature had fallen into disuse, and the boiling pitch, cautery, escharotics, and astringents had succeeded in their place; he is entitled however to the merit of discovering the curved needle. Paré, who was a military surgeon during the reigns of Henry the II., Francis the II., Charles the IX., and Henry the III. of France, is the first surgeon who gives a scientific account of gun-shot wounds, which treatise is truly valuable in consequence of its simplicity. In 1560 Botallus published a treatise "De Curandis Vulneribus Sclopetorum;" and in 1561, Pierre Franco, a celebrated lithotomist, published "Traité des heries, de la pierre, de la cataracte et autres maladies des yeux," a work of considerable merit.

In Italy, there were several surgical authors. In 1563 Fallopius, an excellent anatomist, wrote a treatise "De Ulceribus et de Tumoribus præter Naturam," and in 1597, Caspar Tagliacotius wrote his remarkable work "De Curtorum Insitione per Chirurgiam." Marcus Aurelius Severinus wrote several surgical treatises in 1613, and in the same year, Fabricius ab Aquapendente, a profound anatomist and physiologist, wrote a system of surgery. In 1616, Cæsar Magatus wrote a treatise on wounds, Felix Platerus, in 1614, published his "Observationes in Hominum Affectibus Plerisque," a work of considerable merit; he is the first who treats of the malignant nature of carcinoma. In 1644 T. Bartholimus wrote a work on aneurism.

In Germany and Switzerland, surgery was in the hands of quacks until 1641, when Fabricius Hildanus and Scultetus flourished. The former produced a voluminous work, entitled, "Opera observationum et curationum Medico-chirurgicarum," and the latter an able work, styled "Armamentarium Chirurgicum."

In Holland, the same empiricism reigned until the days of Tulpius, in 1641; J. V. Horne, in 1644, and Ruysch, in 1691. In England the College of Physicians was not founded until the reign of Henry the VIII., in the beginning of the sixteenth century, but anatomy, the foundation of both medicine and surgery, was not taught until two centuries after this. Prior to this period, the bishop of London and the dean of St. Paul's sold licenses and diplomas to the clergy, laity, and empirics, to practise physic and surgery. Bartholomew's hospital was not erected until Henry's reign. Surgery was held in contempt, and practised indiscriminately by barbers, farriers, and sow gelders. Both in Paris and London, in the sixteenth and even the beginning of the seventeenth centuries, the barbers and surgeons' companies were incorporated. In 1676 Wiseman redeemed surgery, by publishing the result of his valuable observations during the civil wars, in his work, termed "Several Chirurgical Treatises."

In France and other countries, many insulated works were published about this period; in 1640 Covillard's "Traité Methodique des principales operations de Chirurgie." In 1681 F. Tolet's Traité de la Lithotomie." Lambert of Marseilles wrote an able work on diseases of the bones, also "Commentaires et Œuvres Chirurgicales," in 1656 and 1677.

The eighteenth century opens with an era of intelligence truly astonishing when compared with the preceding. In France there were Mery, Dionis, Duverney, J. L. Petit, F. Petit, Le Dran, Garengeot, La Faye, Lecat, La Motte, Louis, Maitre, Jean, David, Frere Cosme, Portal, Ravaton, La Peyronie, Quesnay, Faure, Morand, Sabatier, Pouteau, Moreau, Deschamps, and Desault. France has just cause to boast, for having given birth to so many able men.

J. L. Petit communicated his observations on surgery to the Memoirs of the Royal Academy of Surgery in Paris, a truly valuable journal; his communications rank very high, especially that upon the diseases of the bones, and he has the honour of being the inventor of the screwed tourniquet, a most useful instrument; for "the ancients," says a historian, "previous to amputation, only made a tight ligature round the member, from which defect, amputation of a large member was too frequently fatal." Petit was the first who operated for fistula lacrymalis by an incision of the lacrymal sac, and is the inventor of the eighteen tailed bandage.

Le Dran contributed a few papers to the Memoirs of the Academy of Surgery, and published several separate treatises, "Parallele des differentes Maniers de tirer la pierre." "Supplément au parallele." "Observations de Chirurgie." "Traité ou reflexions tirées de la pratique sur les playes d'armes à feu." "Traité des Operations de Chirurgie." "Consultations sur la plupart des Maladies qui sont de resort de la Chirurgie." Some of these are translated into different languages; and his observations and consultations are translated into English, the latter of which are interesting and at the same time amusing, and the operations are well drawn out; his works throughout are replete with many valuable facts and cases.

Sabatier's medicine operatoire is considered so complete on this department of surgery, that additions have been published by Dupuytren, Sanson and Begin. The edition published in 1822, contains every modern improvement in French operative surgery, and in this light is a valuable work; he also communicated some papers to the Academy of Surgery.

Pouteau's Melanges de Chirurgie, and les Œuvres Posthumes, are consulted at the present day, as they contain many valuable facts and observations. The Melanges are translated into German.

The works of Desault deservedly stand very high in reputation. He was the first in Paris who taught surgical anatomy and gave clinical lectures on surgery, one of the most important modes of instruction. He was not less profound as an anatomist than a surgeon, and infused an ardent zeal for both sciences into his pupils, among whom were Dubois, Boyer, and Bichat, who have equalled their preceptor in reputation. He invented several ingenious apparatus for fractures, some of which retain his name, and modified the common amputating knife, converting it from the ancient curved shape to a straight one; he also improved Hawkin's gorget. He renewed the use of the immediate ligature on arteries, which had again fallen into disuse after the demise of Paré, and has the merit of proposing that scientific mode of securing arteries beyond or distant to the aneurismal tumour, in cases where the reverse is impracticable, an operation now perfectly established by the success of Mr. Wardrop and others. He is stated to have been a scientific and dexterous operator, and was the first who attempted to cure an artificial anus formed after strangulated hernia; and also the first who treated scientifically schirrous tubercles of the rectum. In France he is as much esteemed as an authority as John Hunter is in England.

In Italy there were Bertrandi, Mollinella and Moscati.

In Germany and the north of Europe, there were F. Hoffman, Heister, Platner, Bidloo, Bilguer, Callisen, Richter, Ruysch, Trew, Meckel primus, Schneider, Schmucker, and Haller.

Heister wrote an able system of surgery, which is deservedly quoted at the present day; it is a work of extensive practical experience. He appears to have been an able anatomist, a sound pathologist, and a bold operator. Callisen's Systema Chirurgiæ Hodiernæ is an excellent compilation of the day, written by a vigorous mind.

Richter's Medical and Surgical observations are deservedly valued.

Schmucker ranks high as a military surgeon; many of his observations on injuries of the head are quoted by his successors. He published an excellent work in 1774, termed "Chirurgisch Wahrnehmungen," and another entitled "Vermischte, Chirurgisch," Schriften in 1785.

Haller's Disputationes Chirurgieæ, like the other works of this great man, are extensive and elaborate dissertations on surgery.

Great Britain, during this century, produced Chesselden, Douglas, Monro, primus et secundus, Sharp, Cowper, Pott, Allanson, John Hunter, Hill, Warner, Ford, White, Broomfield, Ranby, Gooch, Park, O'Halloran, Dease, Latta, Benjamin Bell, John Bell, and a number of others.

Chesselden's great celebrity consisted in performing the lateral operation of lithotomy so scientifically, that he is said seldom to have exceeded 24 seconds in its performance, he was the greatest operator of his day, and a most profound anatomist. He published a work on the anatomy of the human body in 1713, in which several of the operations of surgery are described, and in 1733 some splendid plates on the healthy and diseased structure of the bones; also a treatise on the high operation for the stone, in 1723.

Monro primus has contributed largely to the pathology of surgery, as, for example, that of luxation of the inferior maxillary bone, of fistula parotidea, of aneurism, of the lacrymal canals, of cataract, of the knee-joint, of caries, of cancer of the mamma, and of the ovarium. He improved the operations of paracentecis abdominis, and amputation.

Monro secundus was a man of great learning, a profound anatomist, physiologist, pathologist, and a most scientific consulting physician and surgeon.

Sharp wrote an excellent treatise on the operations of surgery. Gooch's cases and practical remarks on surgery, and his practical treatise on wounds and other chirurgical subjects are extremely valuable.

Pott's chirurgical works continue the standard of reference, although the doctrine of injuries of the head, hernia, and hydrocele have undergone some modification and improvement since his time.

John Hunter's works continue the admiration and boast of English surgeons. His treatise on the venereal disease, pathological doctrines of the blood, union by the first intention, inflammation and gunshot wounds, are creations of a great and inventive mind.

John Bell's principles of surgery is a work of great merit; his observations on aneurism, especially that by anastomosis, are valuable; he has proved more than the great Haller, that the largest arteries of the human body may be freely secured, without any fear of the collateral circulation not being carried on. It is much to be regretted, that he has written in so diffuse a style, and in so elaborate a manner, as to render the work too voluminous for general reading; again, the style and manner are so peculiarly his own as not to admit of being curtailed. He was a good anatomist, an elegant scholar, and a dexterous operator. He has written on the healthy structure of the bones, ligaments, muscles, heart and arteries; and his work on gunshot wounds is highly prized by the profession. His lectures on anatomy were probably the most eloquent ever delivered in Edinburgh.

We shall now conclude this brief historical sketch, as it will be better to advert to living authors, in the accounts of the different surgical subjects concerning which they have written. We have to refer the reader who wishes further information on this interesting subject to the able article Medicine, in a preceding part of this work; also to the following treatises,—Meibomius; Hippocratis jusjurandum commentariis illustratum, 1643; Le Clerc histoire de la Medicine, 1702; Friend's history of Physic, 1725; Histoire de la Chirurgie par Peyrihle, H. Boerhavii Methodus discendi artem medicam; Halleri Boerhavii Methodus discendi artem medicam; Haller Bibliotheca Chirurgica, 1774; Keisneri Bibliotheca medica; Recherches historiques, et critiques sur l'origine, les divers états et les progres de la chirurgie en France, par Quesnay. Gesner de chirurgia scriptores optimos veterum et recentiorum. Black's historical sketch of Medicine and Surgery, 1782; Gooch's practical treatise on wounds and other chirurgical subjects, together with a short historical account of the rise and progress of surgery and anatomy, 1767; Portal, histoire de l'anatomie et de la chirurgie, 1770; Richerand Nosographie chirurgicale; Prolegomènes histoire abrégée de la chirurgie; also, Histoire des progrès récens de la chirurgie; Sprengel histoire de la Medicine, 1815.

Before concluding, it becomes necessary to make a few observations on the changes or revolutions which have taken place in the practice of the profession. At the beginning of medicine, all its departments were practised by one individual, and it is evident that it was from Hippocrates's universal knowledge he so excelled, and it could have been only from a conscientious feeling of the difficulties attendant on lithotomy, that he separated it from the surgery he wrote upon and practised. Surgery appears then to have been first partially separated from medicine, which circumstance must have contributed to degrade it, as the physicians retained whatever was scientific. It appears to have continued in the most degraded condition until the time of Celsus, who, from his writings, embracing both departments, and evidently practising both, and since he was the companion of the first men in Rome, he must undoubtedly have raised surgery to a high rank in the estimation of the public. In consequence of surgery having no natural foundation at Rome, dissection of the human body being proscribed, it gradually degenerated, and particularly after the suppression of the Alexandria school, when it was again separated from medicine. It is presumptive from the scattered fragments collected by Galen and Cœlius Aurelianus, that surgery must have arrived at great perfection, and been held in high estimation during the flourishing state of that school, when dissection was publicly sanctioned by the government. It is evident from the history of surgery, that it has only flourished according as it has been founded on anatomy, and enriched with medicine or pathological doctrines. At its dawn it was combined with medicine, and in the days of Celsus, Herophilus, Erasistratus, and Galen, it was also united with medicine and founded upon anatomy. After this period, when anatomy could only be prosecuted by stealth, surgery continued in a truly degraded and insulated condition, and in the 11th century was stigmatized by the council of Tours. In the 12th century, the school of Salernum, and also that of Naples, required only one year's study of anatomy for the diploma of a surgeon. In the 15th century we find the great Paré still a barber surgeon, and controlled frequently by the physicians. At Oxford and Edinburgh, the two first universities in Great Britain, anatomical chairs were not established until the last century, and at neither school was dissection prosecuted until this century, and that only at Edinburgh; and even yet throughout Great Britain, the study of anatomy is only prosecuted by stealth; in many schools on the continent, however, its study is sanctioned by the governments, so that it has only been at the dawn of medicine, and in the present era, that surgery has been blended with physic and rendered a respectable profession; and it is much to be regretted there exists any separation, since it only tends to degrade each department; as physicians must be occasionally consulted in accidents, the province of the surgeon; and the surgeon, again, must be acquainted with the treatment of fever occurring from operations. All, therefore, ought to have the same elementary education, and be able to practise every department. The operating surgeon ought to dissect daily. Lately the college of physicians of Edinburgh have wisely rescinded a law, which prohibited their fellows from using the lancet or the scalpel. "Etenim omnes artes," says Cicero, "quæ ad humanitatem pertinent, habent quasi vinculum communem."

Arrangement.

The arrangement of the different surgical affections nosologically, is not so essentially necessary in this place, as it has been already done under the article Medicine, for surgery ought not to be separated from Physic. "La science de l'homme malade constitue un tout indivisible."

The classification, according to the textures affected, is objectionable, on the ground that one disease affects many structures, and frequently proceeds from the one to the other, it has been founded on the healthy division of the textures which has been carried to an extreme, and such has been the baneful influence of Bichat's divisions, that his followers in the treatment of disease have conferred as many lives upon man as the vulgar attribute to the cat. The arrangements adopted by Bell, Boyer, Richerand and Allan are all arbitrary.

As Pathology, and even the doctrines of inflammation have been elaborately detailed under the article Medicine, it is unnecessary to describe them here, particularly when we take into consideration the narrow limits allowed us to include so comprehensive a system as that of surgery. The chief object which shall be kept in view shall be a practical detail of surgery, the grand aim to which all our attention ought to be directed.

We shall first treat of inflammation, a disease which more or less follows all the operations of surgery. Inflammation is a term familiar in common language, and is derived from *inflammo*, to burn or inflame, an expression applicable enough, when we consider the kind of pain excited by a very violent degree of it, and the ideas formerly entertained of the temperaments of our bodies. Inflammation is evinced by pain, increased heat, redness, and swelling, which are caused by a morbidly increased action of the nerves, arteries and veins; and in poisoned wounds, the lymphatics are also involved. The nerves are first thrown into action, which instantly excite the contiguous arteries and veins, and as inflammation increases, the excitement extends to the brain and heart. The pain and heat are more dependent upon nervous than arterial action; in very slight degrees of inflammation, arising from some trifling injury, a sensation of warmth is only felt, in which case it is not completely established, since the phenomenon resembles more an increased healthy action. When inflammation is fully developed from a more severe injury, there is a thrilling pain and intolerable sensation of heat at the moment of receiving it. And if the inflammation be so severe as to threaten mortification, the pain is insufferable. The degree of pain seems proportionate to the distribution of the nerves, and to the density or unyielding nature of the structure affected, which prevents the expansion of the nerves, as is evidenced in toothache, diseases of the bones, &c. To prove that increase of heat is also consequent chiefly on nervous action, a sensation of warmth is experienced instantly after the infliction of the pain, and if a severe blow or wound be received, the sensation of heat is intolerable at the moment of the injury; and not until the inflammation has lasted for some time, does the increased quantity of blood contribute to form the increased heat. The redness is caused by the arteries carrying red blood becoming enlarged in their calibre, and conveying more, for the contractility of the arteries is soon enfeebled by over action, and also by those arteries which previously conducted pale blood or lymph, becoming enlarged and transmitting coloured blood. The capillaries, and communicating vessels between the arteries and veins, and even the commencements of the veins themselves, are similarly dilated. The blood flows with increased velocity, which is caused by that part of the artery which is immediately contiguous, or leading to the inflamed or dilated portion, being morbidly excited.

The artery of an inflamed part therefore is at first smaller than during health, in consequence of the spasmodic action of the nerves, and the distention of the vasa vasorum, diminishing the calibre of the vessel, but it very soon becomes enlarged, from the nerves being partially exhausted and the vessel over distended with blood; while the portion leading to the inflamed part is contracted in diameter. The swelling is first caused by the increased quantity of blood circulating in the blood-vessels affected, and secondly, by a deposition or effusion of coagulable lymph, which appears to occur very early in inflammation. In what is termed the phlegmonous inflammation, of which a common whitlow is a good example, there is generally more or less throbbing present, which is solely caused by the pulsation of the inflamed arteries.

In severe inflammation, the nervous system, the heart, and the whole circulating system, are involved, and constitute inflammatory fever; sometimes the quickened pulse precedes the appearance of the inflammation, while at other times it follows. In the former, the increased circulation, from whatever cause, so excites the nerves and arteries, that they are incapable of returning to their wonted quiescence, and the inflammation may be either partial or general, according as any part of the body is feebler than another. In the latter, the nervous system, together with the heart and arteries, are excited by the diseased action of the nerves of the part affected being transmitted along the nerves to the brain and heart. Our narrow limits will not permit us to examine the humoral theories of Hippocrates, Galen and Boerhaave; the alchemical theory of Paracelsus; the spasmodic theory of Hoffman, Staahl, and Cullen; the excitability and excitement of Brown; the irritation, sensation, volition, and association of Darwin; the materia vitæ conservata, chordæ internunciæ, and materia vitæ diffusa of John Hunter; the debility of the capillaries followed by increased action of the larger vessels, or an inequality in the distribution of the blood, according to Vacca Berlinghieri of Pisa, Drs. Lubboch, Allen, W. Phillip, and Hastings; the increased action of the vessels in moderate degrees of inflammation according to Drs. Thomson, Parry, and James. For further information the reader is referred to the article MEDICINE; to the *Edinburgh Med. and Surg. Journal*, No. 60., and to Lizars's *Anatomical Plates*, part 9, Physiological and Pathological Observations. The great subject of dispute in these theories, is, whether obstruction to the circulation of the blood actually exists in inflammation. That this is the case in well formed inflammation there cannot be the least doubt: but in mild cases, especially erysipelas, there appears no ground whatever for such an obstruction.

Inflammation has been divided in a variety of ways by Hunter, Kirkland, Pearson, C. Smith, Pinel, Bichat, Burns, Thomson, and James. From these great authorities, a very simple arrangement may be formed; for inflammation, whether acute, sub-acute, chronic, phlegmonous or erysipelatous, must be identically the same. Phlegmon and erysipelas are only varieties of inflammation, while the acute and chronic are merely different stages of it. The adhesive, suppurative, ulcerative and gangrenous, are its terminations. Healthy inflammation comes under phlegmon; unhealthy, under phlegmon, erysipelas, and chronic; specific, which embraces scrofula, syphilis, cancer and fungus hæmatodes, evidently involves two diseases in each of these peculiar constitutions; thus inflammation occurring in either the scrofulous, or syphilitic constitution, may be either phlegmonous or erysipelatous, acute or chronic.

Acute inflammation, whether phlegmonous or erysipelatous, is mild or violent according to a variety of circumstances. In a healthy, temperate constitution, with a placid mind, and residing in a salubrious situation and temperature, it is natural to expect the attack will be mild, and more likely phlegmonous than erysipelatous; on the contrary, in a diseased, debauched constitution, with a fretful unhappy mind, and living in a confined filthy abode, we have every reason to expect the attack will be violent, and more probably erysipelatous than phlegmonous. We find, however, phlegmonous and erysipelatous inflammation occurring occasionally in both of these habits. Chronic frequently supervenes after the acute, as for instance, in opthalmia, and in advanced life is occasionally an idiopathic disease. It is ascertained that, according as the part affected is more or less vascular, the progress of the inflammation is more or less favourable. The phenomena of general inflammation are evidenced in acute, or chronic, whether phlegmonous or erysipelatous; and when these symptoms are confined to a small space they are said to be local, and when they extend to, or involve the nervous and circulating systems, the affection becomes general, or constitutes inflammatory fever.

The treatment of local inflammation depends much on the part affected; if a finger, it requires less promptitude than if seated in the eye; generally speaking, local blood-letting, anodyne fomentations or poultices, perfect rest, attention to the bowels, and abstemious diet, are all that is requisite. The treatment of general inflammation is by abstracting blood from the system, both locally and generally, by active purging, tobacco enemata, the warm bath, low diet, perfect quiescence, and confinement in a darkened apartment. By a diligent exercise of these remedies, the inflamed part, or inflamed constitution, may be restored to its wonted state of health; and when local, the vessels gradually become more and more quiescent, until they return to their former healthy condition; but if the inflammatory action has been so severe that the capillary arteries have effused coagulable lymph, then the absorbents are excited to remove this superabundant fluid, and the affected part is longer of returning to health. In the case of the constitution being involved, or a general inflammatory action of the system, the nervous and circulating systems progressively decrease in their excitement, until they at last resume their natural course. Either of these favourable results is termed resolution, but this name is more applicable to the local than the general affection.

A phlegmon, which is derived from φλεγω, *to burn*, is distinguished by the colour being of a dark purple hue, by the inflammation being circumscribed, by tumefaction, and by an intense pain, which soon becomes throbbing; when this tumour is pressed upon with the finger, the purple colour disappears for a moment. In the treatment of a phlegmon, leeches, anodyne fomentations or poultices, gentle laxatives, mild diet, and rest should be ordered; and after suppuration, treated as an acute abscess: it is very liable to suppurate, and when occurring in the axilla or groin is styled a bubo. When these phlegmons occur on the face or scalp, they excite the whole system, and then require the treatment recommended for general inflammation, combined with blisters to the nape of the neck.

The manner of applying leeches is familiar to all. When few leeches can be procured, it has been proposed to cut of the tail while the animal is sucking, that the blood may flow out as fast as it enters; or to incise the inflamed surface with a lancet or bistoury. In order to encourage the bleeding afterwards, the part should be fomented or poulticed, or a cupping glass applied. Leeches are preferable to cupping, in affections of the eyelids and other parts of the face, of the forepart of the neck, the scrotum, the penis, the pudenda and the anus.

Fomentations and poultices are preferable to cold saturnine lotions, in all instances of acute inflammation; heat being more natural and manageable than cold. Caloric subdues the action of the nervous and circulating systems by relaxation and exhaustion, and can be procured either in cold or hot weather; while cold does it by causing torpidity, but not until it is reduced to a very low temperature, and then it is liable to produce mortification. Many authors consider that hot and cold applications should be regulated by the feelings of the patient, but these ought never to influence the practice of the surgeon; for the reason why cold at one time, and heat at another, is more agreeable to their feelings, depends entirely upon the time or stage of the inflammatory action. Thus, for example, cold applied during the incipient stage, will be more liable to produce pain, than when applied in the chronic; again, heat in the chronic stage, is more apt to produce pain than in the acute; and whenever suppuration is established, or the inflammation becomes chronic, heat invariably increases the pain, and should be discontinued, cold then being the better remedy. When heat is employed, it must be kept constantly up by renewing the poultices and fomentations whenever they become cool. Poultices are made of turnip, carrot, linseed, barley-meal, onions, oatmeal, and bread and milk, &c., but their virtues depend more on the heat and moisture, than on the materials of which they are composed; the best probably is one made of oatmeal, in a solution of opium with acetate of lead: they ought always to be so large as to cover a great extent of the contiguous healthy surface. The best fomentation is a decoction of poppy heads and chamomile flowers, with a little opium added. Poultices and fomentations will never promote suppuration, they only appear to do so by moderating the increased action, which, if not attended to, might terminate in mortification; when applied, therefore, in inflammation, before the vessels have advanced to suppuration, they will favour resolution; but if not until the vessels are on the verge of suppurating, they merely moderate the increased action, and hence appear to promote suppuration. The practice of applying alternately cold saturnine lotions the one day, and warm poultices the next, must seem absurd to the most superficial observer.

We have already stated that this variety of inflammation has a more diffused character, and is then termed phlegmonous inflammation, which includes Paronychia, Opthalmia, Cynanchetonsillaris, Pleuritis, Pneumonia, Carditis, Peritonitis, Gastritis, Enteritis, Hepatitis, &c. The treatment of these diseases may be said to be the same as that of phlegmon, or general inflammation, and requires to be combined with external irritants, such as rubefacients, blisters, and moxas.

The causes of phlegmonous inflammation are very various, but they may be classed into mechanical and chemical. Fevers frequently give rise to it. An individual phlegmon is sometimes produced by the irritation of extracting one of the bulbs of the hair. The alternations of temperature is a very common cause, especially when the constitution is not in a healthy condition, either from irregularity of the bowels, intemperance, or distress of mind. The operation of cold on the system in producing inflammation has long been an interesting investigation. When an intense degree of cold is applied for a short period to a part of the surface of the body, it paralyses or arrests the action of the nerves for a time, and also constringes the blood-vessels, which causes a reaction of the contiguous nerves and arteries to overcome this torpidity and obstruction, and produces an effusion of the serous part of the blood between the cutis vera and cuticle. When this intense degree of cold is sustained for a length of time, both nerves and blood-vessels are so overpowered, the former rendered so torpid, and the latter so constringed, that too often they are unable to recover their vitality; and in some instances, even life is destroyed, when congelation of all the structures of the body is the result. According, therefore, to the continuance of so severe a degree of cold, will either inflammation, with recovery of the frost-bitten part be the result, or inflammation with mortification of the part; consequently, on the same principle will a more moderate degree of cold only produce inflammation. In the last case, the nerves are merely chilled or impeded in their functions, while the arteries are constringed, so that reaction is the result, or inflammation is produced. Inflammation of the throat, chest, or belly, arising from wet feet, appears to depend on those cavities being more delicate, sensitive, and vascular in their structure, cæteris paribus, than the rest of the body, or from one of these parts having been formerly attacked with inflammation; for it is a singular fact, that when any part has once suffered from inflammation, it is liable to a relapse from every exposure to cold; erysipelas of the face is probably the most familiar example. The cold must be transmitted from the feet to these organs through the medium of the nerves, and must at first produce such a commotion in the nervous and vascular systems as to threaten general fever, for it is more than probable, if inflammation of these organs did not take place, fever would ensue. This effect of cold must occur more readily when there is any irregularity of the constitution.

Phlegmonous inflammation is said to have its seat in the cellular membrane, but this is evidently incorrect, unless this texture be allowed to form the substratum of all the other structures of the body. This phlegmonous variety generally terminates in suppuration; sometimes, however, in resolution, but seldom or never in mortification.

It has already been mentioned, that phlegmonous inflammation is often so diffused as to involve both the nervous and circulating systems, and constitute inflammatory fever, or synocha, or cauma. See Article Medicine.

Its treatment consists in local and general blood-letting, active purging, tobacco enemata, warm bath, low diet, perfect rest, and the apartment kept darkened. Blood is to be abstracted from the system by the lancet, which may be employed either to open a vein or artery, and the blood should be allowed to flow until fainting ensues, or a marked effect is produced on the constitution; a check must be given to the increased action of the nervous and circulating systems; for it is of no avail in an active disease such as this, to bleed without producing a decided effect on the system. Whenever the constitution has rallied from the effects of the first bleeding, which generally happens in four or six hours, if the violent symptoms are not very materially subdued, a second bleeding should be repeated and carried also to syncope; but much depends on the period of the fever at which blood-letting was first adopted, for it is a law in acute diseases, to modify venesection according to the duration of the disease; further bleeding may be even necessary, but the quantity required then to produce fainting, will generally be very small. Syncope takes place more quickly in the erect than in the horizontal posture, but if the fever be severe, the patient is unable to be raised, even to the sitting attitude.

Besides venesection from the general system, it is generally requisite to abstract blood locally; when the head, for instance, is much affected, leeches or cupping glasses ought to be applied to the temples or nape of the neck. Immediately after the first bleeding, a brisk cathartic of calomel and jalap should be given, and if this does not operate in five hours, a tobacco enema of 15 grains to the pint of water should be administered, and afterwards a dose of the sulphate of magnesia. When the nausea of the cathartics has subsided, the patient should be immersed in a warm bath between 90° and 100° of Fahrenheit, and remain until nausea, syncope, or perspiration occurs. Effervescent draughts may be given every two or three hours. Acidulated drinks may also be allowed, and low diet, consisting of plain boiled vegetables, ripe fruits, farinaceous substances, weak tea with a little milk, and toast water. If the local injury will not admit the patient to be removed into a warm bath, a vapour one may be used while he remains in bed.

In idiopathic inflammatory fever, when all increased action has been subdued, the diet should be gradually and carefully rendered more nutritious; but in the symptomatic, it may generally be increased more quickly, particularly if suppuration has commenced.

Venesection acts upon the system by diminishing the sensibility of the heart, first by removing a portion of the stimulus to the brain, and secondly by lessening the quantity of the stimulus to the heart itself; but this does not always occur in proportion to the quantity abstracted, for some faint from the loss of a very small portion, while others are able to bear the removal of a much larger quantity, and this difference seems to depend on the firmness or flabbiness of the fabric of the individual. In the lean frame, pressure seems to be kept up between the different structures of the system; while in the loose and flabby individual, pressure or support is deficient, in consequence of which, fainting takes place sooner than when the patient is of a firm habit of body; upon the same principle, a person faints sooner from being bled in the erect, than in the horizontal posture; the blood cannot be propelled so quickly and easily to the brain, which organ being deprived of its wonted support or pressure, and also of its stimulus, is unable to perform its functions, and fainting consequently is the result; but apparently more from the want of support than stimulus, a fact which is corroborated by the phenomena in paracentesis abdominis for dropsy of that cavity, and also by leaping suddenly out of bed in the morning, or in raising a patient too quickly after fever, or long continuance in the horizontal posture.

The heart contracts or palpitates more quickly by twelve beats in the erect than in the horizontal attitude, but this varies in different constitutions, particularly in the native of a cold climate, who has resided long in a tropical one. In feeble people it is greater, and in all after eating, drinking, or exercise.

Cupping is performed with a scarificator. See Plate DXV. Fig. 1. glass cups and spirit lamp or syringe. Some art is requisite in the performance of this little operation, for the scarificator must be promptly raised during the transition of the lancets from the one side to the other, to allow them to move freely round; and they should never be set to strike too deep, as they then completely divide the skin, and reach the cellular tissue, the blood-vessels of which are not so large and numerous, and when wounded pour their contents into the cells. In some cases it is requisite to strike twice with the scarificator, crossing the wounds that were formerly made; and in other instances, the cups are applied before the scarificator, in order to determine the blood to the part. Cupping is a most valuable remedy in many diseases, being preferable to leeches in affections of the spine and joints, without being a painful remedy.

Of the two modes of abstracting blood, viz. generally and locally, the latter is on all occasions preferable to the former, as we abstract blood more directly from the diseased part, and in all complaints, even in fever, one organ is more affected than another, consequently general and local blood-letting ought to be combined almost on all occasions.

In the treatment of disease much reliance is placed on the nature and colour of the blood abstracted, and many experiments have been performed to elucidate this interesting point. The spontaneous change of the blood, in passing from the liquid to the solid state, or its coagulation, has also been frequently the object of experiment and investigation. The coagulum appears to form merely from the blood being allowed to remain at rest; and happens in the living body whenever it flows out of its natural channel, or whenever that channel is so enlarged as not to be able to circulate it with its accustomed rapidity and keep it fluid, as illustrated in aneurism, in varicose veins of the leg, and when an artery is secured either for aneurism or amputation. The nature and appearance of the coagulum or clot vary very much according to the state of the constitution, when the blood is abstracted; sometimes it is of a natural purple colour, at other times of a yellow or buff tinge, while at other times again, it is of a milky hue. The buff-coloured blood, named also sizy and inflammatory crust, is occasionally turned up at its edges, and is then termed cupped buffy blood, and not unfrequently presents an oleaginous appearance; this buff colour is in consequence of the red particles falling to the bottom of the coagulum, and leaving the fibrin pure on its surface. To convince us that these peculiarities of the coagulum of the blood, even the buffy coat, ought never to direct us in our diagnosis of disease, or influence us in the slightest degree in our practice, we have only to refer to the experiments performed by Mr. Vines, detailed in the 195, 272, and 284 Numbers of the Lancet. From these it is evident, that the conclusions hitherto drawn respecting the blood of man in disease, are incorrect. Many causes producing sudden death prevent the coagulation of the blood. During pregnancy the blood continues buffy from conception until parturition. In pneumonia, the blood, in proportion to the quantity abstracted, becomes more buffy; in many cases where only two cupfuls are taken, the last is occasionally more buffy than the first; and in some instances, when four or five are abstracted, each cupful presents a different appearance; the first has a natural purple colour, the second a buff, the third cupped and buffy, while the fourth and fifth are again purple. The buffy appearance has been attributed to the magnitude of the orifice of the vein, but this is incorrect; the cupped appearance is certainly a better test of the existence of inflammation than the buff colour, but no weight should be given to either; the milky colour is generally present in diabetic, bilious, and dyspeptic habits. For the chemical composition of the blood, See Chemistry.

In the inflammatory fever, when the head is more affected than any other part of the body, the external jugular vein, the temporal, or the occipital artery, should be opened, as the relief is greater the nearer the blood-vessel is to the affected organ; again, as arterial blood affects the system more quickly and for a longer period than venous, the temporal or occipital artery ought to be preferred to the external jugular vein, as in general one half the quantity of arterial, compared with venous blood, produces fainting.

The operation of opening an artery is termed Arteriotomy, and is now almost exclusively confined to the temporal, in consequence of its being more easily reached, although the occipital, which was preferred by the ancients, would be the most beneficial, from its direct inosculation with the vertebral artery. In the days of Galen the arteries of the hand were frequently opened. In the Medico-Chir. Trans. of Edinburgh, vol. i., a case is mentioned, where the radial artery was opened by Mr. Rhind, surgeon in India. When the temporal artery is to be opened, the patient should be in the horizontal position, with his head resting on a pillow; the operator then feeling the course of the trunk of the artery, as it runs over the zygoma, or one of its branches as it ascends along the temple, places the fore and middle fingers of his left hand on the vessel, in order to render it steady, the one above or distad, the other below or proximad, of the artery, while with his right hand he makes an oblique incision, about half an inch in length, through the integuments down to the artery, with a lancet, cutting as if it were a scalpel. When the artery is distinctly seen traversing this little wound, the surgeon is to make a similar oblique incision of the vessel, cutting it in a contrary direction, or picking it from below upwards, as if he were opening a vein of the arm. See Plate DXVII. Fig. 6. When the necessary quantity of blood has been taken, the lips of the wound are to be approximated, a firm compress made of a roller of calico, about one inch in diameter, as delineated in Fig. 12, applied over it, and a double-headed roller to encircle the head, crossing as often as possible over the compress. See Fig. 8. The wound should be dressed on the third day, either with adhesive plaster, or simple cerate, according to its appearance, and the compress and bandage reapplied. Afterwards it ought to be dressed daily, and the compress and bandage worn for at least a month, as aneurism is very liable to supervene to this little operation. Arteriotomy is preferred to phlebotomy, in inflammation of the brain or eye, especially Iritis.

The opening of a vein is termed Phlebotomy, from φλεψ *a vein*, and τεμνω *to cut*, also venesection or bleeding. Venesection is commonly applied to blood-letting at the bend of the arm, although we sometimes select the external jugular, or one of the veins on the back of the hand, foot, or ankle. It is sometimes performed on the veins of the scrotum; it has been done in the veins under the tongue and on the forehead, but these last are now abandoned. The external jugular is preferred in apoplexy and croup; the veins at the bend of the arm, in general inflammatory diseases and after accidents; those on the back of the hand, foot, and ankle, in very fat people, when a vein at the bend of the arm or external jugular can neither be seen nor felt. In many individuals, the veins at the bend of the arm can only be felt; and in such cases the surgeon should be experienced, and most careful, as a nerve, the artery, or the tendon of the biceps, might be mistaken.

When the hand or foot is selected, it should be immersed in hot water, and retained there during the flow of the blood; and the same should be done when the scrotum is the part affected, and the patient may stand before the fire, as he should be in the erect position.

The manner of opening the external jugular vein, is to place the head of the patient on a pillow, while his body reclines in the horizontal posture; then press with the thumb of the left hand on the vein after it has crossed the sterno-mastoid muscle, and when it becomes turgid, place the fore and middle fingers of the same hand above and below the point to be wounded, which should be in the region of the sterno-mastoid muscle; then with the lancet in the right hand an incision is to be made obliquely across the integuments from above downwards, using the lancet as a scalpel, and when the vein is distinctly seen, it is to be cut upwards as at the bend of the arm. See Fig. 7, Plate DXVII. Whenever the blood has begun to flow, the middle fingers of the left hand are to be removed, but the thumb is to remain until the quantity required has been abstracted, and the wound closed with adhesive plaster, as air may enter in by the wound of the vein and prove fatal; a case of which is detailed in the Lancet, No. 259. No compress or bandage is to be used, for it would check the cutaneous venous circulation of the head.

When the vein at the bend of the arm is the vessel selected, the patient should stand, sit, or lie, according to the effects to be produced. If the intention of the surgeon is to produce fainting at the least expense of blood, as in luxation or rupture, the patient should be held in the erect position, and a large orifice made in the vein in order to remove the fluid quickly. In inflammation of the bowels, the object should be to abstract as much blood as to cause syncope, but not hurriedly, the patient therefore should be placed in the sitting or horizontal attitude, and a large wound of the vein made. During pregnancy we occasionally abstract blood, in order to relieve congestion, and have then to guard particularly against producing syncope or any uterine irritation; we therefore place the patient in the horizontal posture, and make a very small wound.

When a vein at the bend of the arm is to be opened, as represented in Fig. 4 of Plate DXVII, the patient must hold it on the stretch, and have something to grasp in his hand, to keep his fingers in motion, to promote the flow of the blood. The skin must be firmly stretched upwards along the vein, in order to prevent the wounds made in the skin and vein from shifting; and this is generally done with a fillet or bandage, which should encircle the arm twice, as close as possible to the point to be wounded, and be tied with a slipping knot on the outside of the arm. The surgeon then places the fore and middle fingers of his left hand as in arteriotomy, in order to keep the vessel steady, and with his right hand holding the lancet somewhat like a writing pen, he wounds or pricks the skin and vein at once, and gradually cuts obliquely upwards; making the wound in the skin somewhat larger than that of the vein. The blood should flow at the side of the lancet before it is withdrawn; and when the necessary quantity has been removed, the fillet should be unbound, and the vein compressed beneath or distad to the wound with the thumb of the left hand, the arm washed with tepid water, the lips of the wound neatly approximated, and a square compress of linen applied, and then bound up with a bandage rolled round the elbow joint in the figure of 8. The wound should not be dressed sooner than the third day, and then treated according to appearances, either with a new compress and bandage, adhesive plaster, or simple ointment. It not frequently happens, that although the vein is compressed distad to the wound, the blood still flows, which arises from an inosculation with one of the deep-seated veins.

However simple this elegant little operation of venesection at the bend of the arm may appear, yet there are instances of individuals losing their lives, even in skilful hands, in consequence of a high division of the brachial artery into the radial and ulnar, one of which sometimes runs immediately beneath the skin, between it and the fascia of the biceps, and is thus liable to be wounded. A careless operator may transfix the vein and wound the fascia of the biceps or the brachial artery, and thus varicose and false aneurism may be produced: or extensive inflammation of the fascia of the arm, together with suppuration beneath it. Besides these formidable diseases, there are ecchymosis, inflammation of the vein, of the skin, of the cellular substance, of the lymphatics, and the wound of a nerve, which may all occur after venesection at the bend of the arm.

Ecchymosis, from εκχυω, *to pour out*, is an effusion of the blood into the cellular tissue, contiguous to the wound in the vein, occasioned by the wound in the skin not corresponding with that in the vein, or the wound of the one not being kept in apposition to that of the other during the flow of the blood, or from the integuments overlapping the wound in the vein, the skin not having been braced with sufficient firmness by the bandage ; or lastly, by not making the wound in the skin a trifle larger than that in the vein. When the blood forms a circumscribed tumour, it is termed a thrombus, from θρομβος, *coagulated blood.* The one, therefore, is a circumscribed tumour, and the other a diffused effusion of blood; they both require the same treatment, and unless the quantity of blood be profuse, either effusion is of little consequence, and requires no attention. If however the effusion be extensive and produce pain or inflammation, poultices should be applied and continued until all inflammatory tendency has subsided. The inflammation induced, seldom or never ends in suppuration, even of the lips of the wound. If the ecchymosed fluid does not disappear, and the lips of the orifice are healed, but not otherwise, it may be discussed by exciting absorption by means of stimulant embrocations. All surgical operations are followed by more or less ecchymosis, according as the parts may have been torn or bruised during the operation; but it even supervenes in a slight degree in operations most scientifically performed, especially in the face and other delicate parts of the body, as the knife cuts on the principle of a saw.

Too often from an over anxiety to heal the wound inflicted in phlebotomy, it is dressed the day following the operation, the consequence of which is, that the process of adhesive inflammation is disturbed, and too great a degree of inflammation is excited, which either spreads all over the arm, confining itself to the skin, and assuming commonly the erysipelatous type, or involves the subjacent cellular tissue, forming erysipelas phlegmonodes, or extends to the fascia of the arm, or affects the lymphatics, or the vein itself.

Inflammation of the vein is also said to arise from foul lancets, which however appears to be very seldom the case; nevertheless, a vein ought never to be opened by one which has been employed in opening a syphilitic bubo, or in performing vaccination. When a patient requires to be bled twice in the course of twenty-four hours, a common practice is to abstract the second quantity of blood from the same orifice, by applying another bandage round the arm above or proximad to the wound, until the veins become swollen, then removing the first bandage, and tearing away the compress adhering to the wound, when the blood commonly springs out; but if not, the wound is forcibly opened either with the fingers, or by squeezing the blood along the vein onwards to the orifice, or by inserting a probe or lancet; such teazing steps are even pursued in a third bleeding, if performed in twenty-four hours. If there is not much inflammatory action present, and the second bleeding is performed within twelve hours of the first, this plan may be adopted; but if otherwise, it is extremely liable to produce inflammation, as the adhesive process takes place very quickly between the lips of a vein and so small a wound in the skin. It is therefore preferable to open a vein of the opposite arm. The same vein is sometimes opened close to the first wound in the course of twenty-four hours, which is also an improper practice; and neither this, nor opening the same wound twice, should be adopted in hospital practice, particularly in thoracic inflammation, as the veins are more liable to be inflamed, when lanced in this, than any other disease.

Inflammation of the vein is characterized by tumefaction of the arm, pain in the wound darting to the axilla, and even to the thorax, accompanied with difficult respiration and inflammatory fever, which advances rapidly to typhus. The vein to the touch feels hard, is very tender, and sometimes inflamed both upwards and downwards; the lips of the wound are everted, swollen, and occasionally pus or sanies, mixed with blood, can be pressed out from it. Not unfrequently there is an œdematous boggy feeling in some parts of the arm, with more or less inflammatory discolouration of the integuments. On dissection, the vein is found so thickened in its coats, that it has all the appearance of a nerve; and coagulable lymph and pus are deposited in its cavity, sometimes to the extent of plugging it up; the internal coat is of a reddish purple colour, resembling claret. There is more or less effusion of purulent matter in the contiguous cellular tissue, and even in that entering into the formation of the muscles, and in some instances the two pectoral and the contiguous intercostal muscles are infiltrated with pus. The pleura is often found inflamed, with abscesses forming in the lungs; and sometimes the right auricle and ventricle will also be inflamed, with even pus in the pulmonary artery. Inflammation of a vein proceeds with great rapidity, and as veins circulate their contents onwards to the heart, the inflammatory action is conveyed to this viscus with alarming celerity, frequently proving fatal between the fifth and tenth day. The coagulable lymph and purulent matter effused into the veins, must also be carried onwards to the heart. From these alarming consequences, it is evident that the treatment of this disease must be very prompt. The patient should be bled to syncope by opening a vein of the neck or opposite arm, and this ought to be repeated in four hours, or whenever he rallies, and until all inflammatory tendency has been subdued; and as there is a disposition to inflammation in the venous system, the same vein ought never to be opened twice. Together with active blood-letting, should be combined tobacco enemata, brisk cathartics, warm bath, a profusion of leeches to the part affected, or scarifications with the bistoury, represented in Fig. 2, Plate DXV, followed by large anodyne poultices, or fomentations, with low diet and perfect quietness. When scarifications are made with the bistoury, the wounds should be plugged with lint, after a requisite quantity of blood has been abstracted. If these local applications do not seem to arrest the extension of the disease, large blisters should be applied. The general treatment in all these affections is the same with that recommended for inflammatory fever. John Hunter and others have recommended pressure on the vein both above and below the wound; but we should rather consider, that the compression would increase the inflammation; Mr. Abernethy proposes the division of the vein, a line of practice certainly preferable to that of Mr. Hunter.

Inflammation of the lymphatics begins by the wound appearing fretful, inflamed and suppurative, by a cord or cords being felt sometimes above or proximad, and at other times below or distad to the wound, but not precisely in the course of the vein. These cords appear of a delicate rosy red colour, are exceedingly tender to the touch, and have frequently one or more tumefied points on the inner or ulnar margin of the biceps muscle, in the course of the brachial vessels; similar tumours are also often seen on the fore-arm, between the elbow and the wrist joints. The glands of the axilla become early affected, and there is general tumefaction of the arm, with acute pain in the wound, in these corded lines and tumours, accompanied with considerable symptomatic fever. Either before or after the inflammation of the lymphatics, the contiguous cellular substance becomes very early involved, frequently producing extensive suppuration of both, which also spreads to the axillary glands, in which case there is more or less œdematous feeling. According to the extent of the affection, the treatment requires to be either entirely local, or both local and general. The same remedies, with the exception of blisters, are to be employed as in inflammation of the vein, and need not again be described.

Inflammation of the fascia of the arm commonly takes place, when the operator has carelessly transfixed the vein and wounded this membrane; but this accident may occur in the most skilful hands, for occasionally the most prominent vein at the bend of the arm, and the one any surgeon would select, runs beneath or centrad to the fascia of the biceps. The symptoms of this affection are acute pain in the arm, extending to the shoulder, whenever the fore-arm is moved, which latter is in some degree bent on the arm, with the fingers also bent and contracted. There is great tension, some degree of tumefaction in consequence of anasarca, and slight erysipelatous inflammation; there are also generally sympathetic spasms over the whole body.

As suppuration quickly supervenes, with thickening of the fascia, and consequent contraction of the elbow joint and fingers, the treatment should be extremely prompt, this affection being strictly erysipelas phlegmonodes, consequently the same means should be used as for inflammation of the vein: and in the event of contraction resulting, the fascia of the fore-arm must be divided either at its connexion with the biceps muscle, or what is preferable, immediately below or distad on the pronator and flexor muscles, avoiding the course of the veins and nerves, and even the ulnar artery in case of a high division of the brachial. When there is great tension during the inflammatory stage, accompanied with severe pain, the fascia even then should be divided.

A nerve at the bend of the arm is extremely liable to be wounded in venesection, in consequence of the twigs of the internal and external cutaneous nerves, and even some of the spiral nerve entwining the different veins. When a nerve is wounded, the patient feels acute pain the moment the lancet pierces the vein, and inflammation of the wound follows, the nervous symptoms immediately commence, and acute pains are experienced darting along the arm, to the neck and head, and even down along the fingers; convulsive twitchings ensue, accompanied with restless nights, being disturbed by frightful dreams. When inflammation of the wound does not take place it heals up, and some days, even weeks, elapse before the convulsive symptoms begin, and in this case, which is the more rare of the two, it resembles tetanus more than the other. On some occasions it assumes the appearance of neuralgia. If the convulsive symptoms have been severe, in a few days spasms occur which dart from the head along the back and bring on trismus or locked jaw, which puts an end to the patient's sufferings.

The treatment of this affection in the first noticed case, requires to be very prompt. The wounded nerve must be divided close above or proximate to the wound, the arm enveloped in an opiate poultice, having half an ounce of opium dissolved in half a gallon of water, and if this should not give relief to the patient, the actual cautery should be applied to the wound. The patient ought to be bled in the other arm, or jugular vein to syncope, put in the warm bath, have powerful cathartics given, followed by large doses of opium, and have tobacco glyster administered. The bleeding to be repeated as frequently as circumstances require; and if all these remedies fail to subdue the tetanic symptoms, a vein of the opposite arm should be opened, and a solution of opium injected into the circulating system.*

We have already mentioned the most common cause of inflammation of the skin supervening to venesection at the bend of the arm, and it may also arise from the same causes as those producing inflammation of the vein and lymphatics; and we have already stated, that the variety of inflammation which generally occurs here is erysipelas. This variety then, or type of inflammation, for it appears nothing else, has been divided by authors into a number of species, as may be seen by consulting the works of Cullen, Bateman, Pearson, Smith, Pinel, and James, for it attacks the same structure as the phlegmonous, thus the velum pendulum palati is as often affected with erysipelatous as with phlegmonous inflammation; the former named cynanche maligna, the latter cynanche tonsillaris.—We shall confine ourselves to erysipelas, and erysipelas phlegmonodes.

Erysipelas from ερυω *to draw* and πελας *adjoining*, termed in common language *rose*, or St. Anthony's fire, when it occurs after blood-letting at the bend of the arm, begins in the contiguity of the wound, and soon spreads both upwards and downwards, frequently involving the whole arm, which becomes swollen, the skin assumes a delicate rosy tinge, and is clear and shining, and when pressed gently with the finger, a white mark remains for a little. A yellowish hue is frequently observable, and there are occasionally serous vesicles which either dry up, or burst and desquamate, or ulcerate, or slough and ulcerate. The patient feels a hot burning pain in the part, and when the constitution becomes affected, which is early in the disease, there is inflammatory fever with considerable nausea. By some it is stated, that the wound of the vein often heals before the erysipelatous affection takes place, and continues so, while on other occasions it breaks out. The treatment is the same as that recommended for inflammation of the vein; for bleeding, blisters, poultices, and anodyne fomentations, are as proper remedies for the one affection as the other; but if there be any tension, incisions should be made as in erysipelas phlegmonodes. The reader is also referred to the treatment of inflammatory fever, and the Article Medicine, Vol. XIV. Page 4.

In this disease, a vein opened in the opposite arm never assumes the erysipelatous type; nor do leechbites, according to the common opinion, mortify; blisters often arrest the extension of the inflammation, and the blistered surface never assumes the erysipelatous action, but, on the contrary, limits it. Warm poultices are as beneficial in erysipelas as in phlegmon. Flour is a common but most inert application. A solution of the sulphate of magnesia, with tartrate of antimony, is found to be an excellent aperient. Emetics are pernicious remedies, particularly when the head is the seat of the disease, as they propel the blood to that organ. When erysipelas attacks the face or scalp, it ought to be treated with great promptitude, in consequence of the vicinity to the brain; and when once either of these parts have been attacked, it is peculiarly liable to return on the slightest exposure to cold. It is also very apt to move from one place to another, in this manner, extending all over the body, from the head down the back and breast to the arms and even the legs, the one part desquamating as the other makes its appearance. It is likewise subject to be translated from one part of the body to another like rheumatism, from the leg to the lungs or face, and it has been known to occur periodically. The integuments of the head are particularly prone to erysipelas after all wounds, especially punctured ones; it also often occurs after compound fractures of the leg, and occasionally in the anasarcous leg. It not unfrequently attacks the umbilical region of new born children, and extends along the umbilical vein, or downwards to the pudenda. Erysipelas is described as being confined to the skin, and when it involves the subcutaneous cellular tissue, it is termed phlegmonous erysipelas, or erysipelas phlegmonodes, or diffuse inflammation of the cellular texture. The epidermis, the rete mucosum, the cutis vera, the cellular tissue, and the cellular substance forming the aponeurosis of the muscles, have all individually and collectively been supposed by authors to be the seat of erysipelas.

We find erysipelas attacks mucous structures, as the mucous membrane of the fauces, and we feel confident that we have seen it evidenced in other textures, as the serous, namely the pleura and peritoneum, also fibrous textures, as the periosteum, and we can see no reason for its not attacking every tissue. Erysipelas phlegmonodes is distinguished from simple erysipelas, by the part affected presenting a combination of the two colours, the vermilion and purple, and often a yellow tinge, by the œdematous boggy feeling, and by the patient having rigors or shiverings. An œdematous spongy sensation is one of the best criteria of suppuration having taken place. Whenever matter can be distinguished, free incisions should be made to evacuate it, and as it is often diffused over a great extent, these require to be numerous. If much tension is present, or if the disease be severe, it will be advantageous to make these incisions even before suppuration has taken place, as they not only relieve the tension, but moderate the inflammation by the local abstraction of blood. Instead of short, or moderately sized incisions, as first

* Cauteries are divided into the potential and actual. The potential consists of the different escharotics and astringents, as the sulphates of alum and copper, and nitrates of silver and copper. The actual cautery is an iron heated to incandescence and the moxa. The irons used for cauterizing are of various shapes. The moxa is made of common cotton immersed in a solution of the nitrate of potass (of the strength of five grains to an ounce of water) and afterwards dried. A small quantity of this cotton is firmly rolled up and encircled with a piece of card half an inch broad, and three inches long, and afterwards tied round with a thread. It is then fixed in a *port-feu* (See Plate DXV. Fig. 3) the one end set fire to, and the other held firmly on the part to be chemosed. The common bellows are then employed to keep up the ignition of the cotton, which now resembles a common fuse, until it is entirely consumed. The ignition should be merely kept up, for the more slowly it burns, the more powerful is the effect.

recommended by Mr. C. Hutchison, Mr. Lawrence makes a long incision, even the length of the leg, which is evidently objectionable. Erysipelas terminates either in resolution, suppuration, vesication, or gangrene. When resolution, or an abatement of the disease is the termination, the skin assumes a pale yellow colour, and ultimately the cuticle desquamates.

When gangrene supervenes, the parts become first bluish and then black; an inflamed line of demarcation next takes place between the sound and the mortified parts, ulceration succeeds, and the gangrened parts slough or sphacelate, and sometimes leave the principal artery of a limb exposed. In dissection of the more severe cases of erysipelas, the cellular tissue of the arm is universally gangrenous, even that forming the basis of the muscles, which texture is also distended with a sanious fluid. There appear no grounds for considering erysipelas infectious, and it is even doubtful how far it is contagious; nevertheless, in this as in all other diseases, every attention should be paid to cleanliness and ventilation. The treatment will be detailed under mortification.

Paronychia, or Whitlow, named also, Panaris, Onychia, Onychia maligna, and Panaritium, is so common an infection attacking the finger, that all are familiar with it; writers, however, make out a number of species, as detailed in the Edinburgh Medical Journal, No. 95, which subdivision appears truly frivolous and unnecessary; in general, the less the finger is diseased, the more the hand, fore-arm, and arm are affected. It is usually a phlegmonous inflammation attacking the finger near the point, but sometimes is erysipelatous, and arises from a variety of causes, some of which are occasionally very obscure, or entirely unknown. The causes are commonly cold, a piece of the nail fretted, or what is vulgarly termed rag-nail, a prick or wound in the finger from a thorn, small splinter of wood, needle, hook, scalpel, forceps, spicula of bone, a broken bottle, an abrasion, or dirt getting access to the cutis beneath the nail. The finger affected generally presents a swollen inflamed appearance, and has a painful hot throbbing sensation. In some cases the malady is confined to the nail and its vicinity; in others the finger feels acutely painful, the pain extending to the hand and fore-arm, with little or no tumefaction; in others again, the pain is confined solely to the finger, unaccompanied with tumefaction. When confined to the nail and neglected, there commonly shoots forth a fungoid excrescence, and the finger becomes swollen and deformed. From what has been stated, a whitlow may be considered a disease of the finger, of an inflammatory nature, attacking one or all the structures, rapidly terminating in suppuration, and occasionally in gangrene even of the bones; and as the inflammation, suppuration, and gangrene are liable to extend upwards along the arm, fatal consequences may ensue.

As the finger is exceedingly sensitive and vascular, whitlow should be treated early and vigorously. If the finger be merely inflamed, and no degree of tension, warm poultices, with absolute rest and low diet, will be sufficient; but if there is tension, or matter apparently secreted, a longitudinal incision of some depth should be freely made in the centre of the finger, and generally on the palmar aspect, to give relief, and to extract blood locally. When the cuticle acts as a sheath, and restrains the expansion of the inflamed finger, it ought to be cut off with scissors; and when matter insulates the nail, the latter should be removed with scissors and forceps, otherwise a fungous excrescence germinates around it, forming what is termed *ulcus mali moris*, or in common language, the growth of the nail into the flesh, when the slightest motion causes exquisite pain. The nail then is more difficult to remove, produces more pain, and the excrescence requires to be removed with the scalpel and escharotics, or both. The best escharotic is the nitrate of copper. This latter variety often attacks the toes, especially the great one, and various ways have been devised to remove this source of irritation, by Paré, Dupuytren, and Wardrop, the last of which is the preferable, and is detailed in No. 209 of the Lancet.

If the hand be involved in the disease, it should be treated as recommended for inflammation of the vein, and if the inflammation still continue, one or two incisions should be made in the palm of the hand, to divide the palmar fascia so as to remove the tension and obviate permanent contraction of the hand, care being taken not to wound the palmar arch of the ulnar artery, an incision may be also necessary on the back of the hand. If the disease extend to the fore-arm or arm, the same treatment will be required as in inflammation of the fascia. In this affection the phalanges of the fingers become soon carious, proving the necessity of active treatment; and whenever the bone or bones are ascertained to be bare or rough, they should be removed either by extracting them individually or by amputation; on some rare occasions, the finger degenerates into a carcinomatous condition, and requires to be amputated.

The fascia palmaris, especially the threads extending along the fingers, is frequently so contracted from this malady as to impede the functions of the fingers or even the whole hand, and should therefore be divided by a cross incision, the fingers being afterwards held out straight by a piece of wood. From an attentive examination of such fingers in the dissecting room, we can speak with confidence of the nature of this contraction; the tendon being only gradually contracted, in consequence of this arch of the fascia palmaris being so: and from the different positions in which the fingers are held, the same derangement takes place in their joints, which progressively become dislocated.

Pure and simple whitlow, the most common affection resulting from punctures in the dissecting room, is frequently produced from the puncture of a hook, scalpel, forceps, needles, or the spicula of a rib, in the examination of the thoracic viscera. In the mildest cases, there is merely a small serous vesicle of a milky colour, from being filled with a fluid more or less purulent, and surrounded with an erysipelatous or phlegmonous blush. In the severest cases, the disease is either at once ushered in with rigors, high constitutional excitement, advancing rapidly to typhus, with a peculiar despondency of mind, or the inflammation extends along the fore-arm and arm to the axilla and thorax, involving the muscles of the axilla, those situated on the thorax, and even those on the abdomen and back, resembling erysipelas phlegmonodes, or inflammation of the fascia consequent on venesection at the bend of the arm: indeed the only difference between these affections is, that in this originating from a puncture in morbid dissection, we have frequently no chain of connection between the puncture and the muscles and cellular tissue of the axilla; but the same want of connection, or cause and effect, appears to exist in erysipelas and a wounded nerve succeeding to phlebotomy. There can scarcely be a shadow of doubt, that in one and all of these affections, some exciting cause must have existed; and that although the wound healed in either without being observed, yet nevertheless it must have inflicted irritation or excitement, or a morbid action, either in a lymphatic, a nerve, or a blood-vessel, which has not been called into action until the constitution was excited either by stimulation or by fever induced by cold. We have known many by dining out and indulging in wine, rouse to action such punctures even when healed; also if afterwards attacked with febrile symptoms induced by cold. The lymphatic vessels appear to be those which suffer, because the axilla is the most frequent seat of the first development of this affection, and yet the glands situated there are seldom affected. The greater number of individuals are affected in consequence of being punctured while labouring under some febrile attack. The mind has a powerful influence in this disease.

Assuming this view of our theory to be correct, we must next ascertain whether any poisonous matter is absorbed. The fact of the same affection being produced by clean lancets, clean needles, common skewers, delicate splinters of wood, various kinds of thorns, the spiculæ of the bones of the ox or sheep, broken glass, or an abrasion of the finger against a wall, should at once put to rest the idea that absorption has any concern in producing such a disease; for since to the same causes we are entitled to ascribe the same effects, why should we search for the unknown and fanciful, when such simple and natural causes are before us? Before the time of Paré, musket bullets were supposed to be poisonous, and there are modern authors who are so credulous as to believe, that Malaria travels, like the carrying pigeon, from Italy and Holland to London!

Some authors assert, that recently dead morbid animal matter is more poisonous than putrid, while others the reverse, and some think that the saline solution employed in injecting dead bodies is a corrective. If what has been advanced be correct, it follows that putrid dead morbid matter, and saline dead morbid matter, should be more irritative than recently dead morbid matter. We do not mean to deny, that putrid dead morbid matter may be absorbed, although it is well known that the syphilitic virus and many other living animal poisons cease to affect the living system the moment death takes place; but we do mean to deny, that absorption occurs in punctured wounds, producing erysipelas phlegmonodes or diffuse inflammation of the cellular tissue. By some a specific virus is supposed to be generated in the dead body, but this appears fallacious if we are correct in our theory. It is also imagined that this virus is absorbed even when the skin is sound in those constitutions considered to be peculiarly susceptible of the impression of dead animal matter, and that gloves, oil or lard, are excellent prophylactics; but that these are totally inert there appears scarcely a shadow of doubt. Some authors contend, that a person engaged in dissection, will resist this disease and the putrid effluvia better if his diet be nutritious; but the very reverse ought to be the case.

With regard to fever, we have already stated, that idiopathic inflammatory fever is caused by the application of cold to the body while heated. The same appears to be the cause of all other fevers with the exception of hectic, so that we are of opinion that neither putrid effluvia, marsh miasmata, nor pestilential vapours, ever give rise to fevers. These effluvia appear only to render the constitution ill-conditioned and feeble, and more susceptible of cold, and hence, when attacked with fever, make it more violent.

The treatment of this variety of erysipelas phlegmonodes, originating from punctured wounds received in morbid dissections, is as various as its theory, which must ever be the case so long as we are ignorant of the correct pathology of the disease; it equals the farcical medley of a thousand remedies as applied to ulcers, so humorously described by John Bell. When suppuration is established, all are agreed that vent should be given to the matter by free incisions. Nor has the general treatment been more consistent than the local. The treatment of this should be the same as that recommended for erysipelas phlegmonodes. See also inflamed vein and inflammatory fever. In the last stages of this fearful affection, as in other fatal disorders, hiccup, which is an inverted action of the stomach and diaphragm, is no unfrequent concomitant, and is easily checked by the patient sipping any bland fluid, swallowing it constantly without intermission until the hiccup ceases; and afterwards he must avoid speaking, for it is exceedingly liable to recur, sneezing and coughing reproducing it.

Adhesion is that termination of inflammation which takes place when the inflammatory action is moderate, and coagulable lymph only is secreted: in common phlegmon, this occurs very soon after the increased action has begun, the lymph being effused into the contiguous cellular tissue, which limits the extension of the inflammation. It takes place also in all acute abscesses, and in all incised wounds, whether accidentally or intentionally inflicted. Adhesive inflammation or union by the first intention, although a termination of inflammatory action, begins a new series of operations, and its doctrine being one of the most interesting and important in surgery, has engaged the pen of our most able pathologists. When a clean incised wound is made, such as that in amputation of a limb, and the sides of such a gap are made to approximate, the first process in nature to effect a reunion, is a moderate degree of inflammation, by which coagulable lymph is effused, which appears to be effected by a modification of the capillary arteries, influenced by the nerves, to secrete this organizable fluid. That coagulable lymph is a secretion, appears evident from the consideration that in slight degrees of inflammation of serous membranes, it is unquestionably secreted, and in abscesses and ulcers it is poured out in profusion; that in fractured bone it is a pure secretion; that in incised wounds, the blood acts as a foreign body, and that every fluid, either healthy or diseased, is secreted, or undergoes modification in vessels; it is also one of the simplest of diseased secretions. The bleeding of a wound must have entirely ceased before coagulating lymph can be effused, hence it appears that some modification of the bleeding or capillary arteries, influenced by the nerves, takes place. This coagulating lymph differs from that obtained when recent blood is allowed to coagulate, by being of a lighter colour, nearly transparent, like animal jelly or made starch, and being more tenacious, also more organizable.

The common doctrine of this lymph either issuing from the half-closed mouths of the vessels, or from the surface of the opened cells of the cellular substance, seems incorrect. After this coagulating lymph is effused, the capillary arteries and veins of each side of the wound shoot into it, soon rendering it a firm bond of union; and an inosculation has been proved to take place in the short space of twenty-four hours. In inflammation of the serous membranes, the pleura, pericardium, peritoneum, internal tunics of arteries, &c. the degree of the inflammatory action is often exceedingly mild, and the duration very short which accomplishes adhesion, apparently almost as soon as inflammation is established, the serous secretion is checked and that of coagulable lymph substituted. On the principle of this adhesive inflammation, are the various incised wounds healed, also as the renovation of a nose, or under lip, or a deficiency of the urethra.

The formation of a new nose or under lip, when either of these has been removed by accident or some previous disease, was first practised in India by Branco, afterwards by Tagliacotius in Italy and Germany, and is now termed the Talicotian or rhino-plastic operation. Tagliacotius used to take a piece of skin off the arm or some other part of the body to make the new feature, upon which Butler has written a humorous stanza, and Addison an amusing paper. It is now performed by taking a piece of the integuments in the vicinity of the feature, from the neck when it is the under lip, and from the forehead when the nose. The latter operation is performed in the following manner:—A piece of leather is cut the shape of the nose, and placed upon it, or where the nose should have been; and, if any skin remains, it is removed, and the margins rendered raw by clean incisions; when all bleeding has ceased, the leather is then laid upon the forehead, and traced round either at once with the scalpel or pen and ink; this portion of the skin is then dissected off from its attachment to the occipito-frontalis muscle, taking along with it as much cellular substance as possible, and leaving a tolerable point of connection at the root of the nose; it is then gently twisted round, and laid upon whatever remains of a root or dorsum, making it correspond with the surface already rendered raw for its reception, only a degree larger; and lastly, stitching it with two silk ligatures on each side of the nose, and one at the columna. If the skin to form the new nose has no support in consequence of the columna and cartilaginous septum being destroyed, it should be gently supported with dossils of lint inserted in each naris; but if there be enough of septum to prevent the skin hanging or dragging, no foreign body should be inserted, as all source of pressure or irritation ought to be carefully avoided. Whenever adhesion has been effected, the nose should be supported by silver tubes. The raw part on the forehead should be approximated with stitches as much as possible, and afterwards healed like any ulcerated surface. Whenever adhesion is perfect, and all irritation and tumefaction have subsided, the little twisted portion of integuments that formed originally the point of connection should be divided, and laid neatly down.

Before performing this operation, the surgeon should be satisfied there is no constitutional affection present, and in those cases where the nose has been destroyed by *noli me tangere*, all tendency to this herpetic ulceration ought to have entirely ceased. If a small portion of the skin of the old nose remains, it had better be removed, as it will disfigure the countenance by a contrast of colours.

Suppuration is another termination of inflammation. Whenever the inflammatory action is more violent than what is necessary for the capillary arteries to secrete coagulable lymph, these capillaries, modified and influenced by the nerves, form small suppurative papillæ that secrete purulent matter, which theory of action constitutes suppuration. When this ensues from acute inflammation, and the matter is circumscribed or confined in a sac, the disease is named acute abscess; for we have purulent matter, or a puriform fluid secreted by mucous membranes, which are the most subject to this termination of inflammation. It is also secreted in incised wounds, and in the skin or cutis vera after a scald with boiling water or the application of a blister. In mucous membranes, such as the urethra, the capillaries are naturally endowed with the power of secreting a mucous fluid; and if these vessels are inflamed, they are easily and quickly modified by the nerves, to secrete a puriform fluid, as for example in Gonorrhœa, occasionally twelve hours after infection. In this case the capillaries do not seem to form suppurative papillæ, as in common suppuration and ulceration. In the cut the capillaries perform the functions of exhalants naturally, so that when stimulated by a blister, they are soon modified by the nerves to perform the function of secreting purulent matter; and if the irritation be kept up by blistering ointment, they soon form suppurative papillæ. In incised wounds, the capillaries perform the same office as in ordinary suppuration; small suppurative papillæ being rapidly formed and then pus secreted. In all cases of suppuration there must be a precedence of inflammation, however slight in degree, even in scrofulous tumours or abscesses. All loose textures, as the cellular, when attacked with inflammation, are more prone to terminate in suppuration than condensed compact structures, because the blood-vessels have greater latitude to form suppurative or ulcerative papillæ.

The symptoms of suppuration are rigors or cold shiverings, which occur at irregular intervals, and are commonly followed by a hot fit and slight increase of the preceding febrile symptoms, if the inflammation has been extensive; a total quiescence of the pain of the inflammation for a time, which is soon resumed if the hot applications are continued, especially if the suppuration be superficial. In a short while the pain returns, but changed to a dull, heavy, and constant feeling; the tumour becomes conical, with a white or yellow tinge at the apex, while the surrounding inflammatory colour is deeper and the skin more glistening; there is occasionally more or less of an œdematous feeling, and matter is then distinguishable to the fingers. One of the best examples of an acute abscess, is the termination of an inflamed inguinal gland in suppuration. Whenever the fluctuation of matter is perceptible in a circumscribed acute abscess, a free incision should be made from the one end of the tumour to the other, with the bistoury; but in an extensive or diffused abscess, the most depending part should be selected to make the aperture. Unless a free incision is made in the circumscribed abscess, the matter is liable to loiter at one of the extremes, and form a sinus or sinuous ulcer or tube, which afterwards requires to be laid open, an event frequently exemplified in the syphilitic abscess. Some authors recommend that abscesses should be allowed to break of themselves, while others recommend caustic instead of the bistoury, but the knife is preferable, as it inflicts less and more transient pain, makes an aperture proportionate to the abscess, and prevents the disease making further progress. After the evacuation of the matter, poultices should be applied for the first twenty-four hours, when the wound ought to be dressed with simple dressings, compress of tow, and a calico roller; and in the case of the groin being the seat of the disease, the bandage should encircle the body and the thigh in the figure of the digit 8. The periods of dressing an abscess must depend on the quantity of matter secreted. In ordinary cases, once or twice in twenty-four hours is sufficient.

In those cases of acute abscess of the palm of the hand, fore-arm, arm, thigh or leg, where the matter is situated beneath or centrad of the fascia, there is generally a dull cutaneous inflammatory discolouration, and an œdematous feeling, which, with the other symptoms already enumerated, indicates the presence of matter. In such cases the fascia must be freely divided with the bistoury. An œdematous boggy sensation is the best index of matter being secreted, yet it is often exceedingly difficult to distinguish its presence; the *tactus eruditus* is a valuable acquisition to a surgeon. When an acute abscess is examined, it is coated with coagulable lymph of a smooth membranous-looking ash colour, which is termed the sac or cyst, and adheres by a vascular cushion to the surrounding cellular substance, the latter of which, in the vicinity of the abscess, is more dense and vascular; and its cells are closed with coagulable lymph. In this vascular cushion and stratum of coagulable lymph, the capillary vessels modified to secrete the purulent matter are situated, together with the nerves, veins, and absorbents. In all abscesses, a secreting and absorbing action is going on. A remarkable circumstance is that an abscess advances almost always to the surface of the body, which has been attempted to be explained on the principle of plants growing towards the light. It appears, however, more probable from the skin offering less resistance, for when matter is deposited beneath a fascia, it burrows in all directions. The matter secreted in an acute abscess, occurring in a healthy constitution, is named pus or purulent matter, and is of a yellow cream colour, and about the consistence of rich cream. For its chemical properties the reader is referred to the article CHEMISTRY. Pus slightly irritates the contiguous skin of an abscess or ulcer, and even the granulations: therefore, from these fretting qualities, it ought to be absorbed by lint and tow as soon as secreted.

An abscess, when freely opened and dressed daily with simple dressings, gradually fills up by the formation of suppurative papillæ or granulations, and when these arrive to be nearly on a level with the skin, it is generally termed an ulcer: an ulcer, therefore, is simply a diseased, or abraded secreting surface, (for there are numerous healthy secreting surfaces,) and has been correctly defined by authors to be a solution of continuity in any of the soft parts of the body, attended with a secretion of pus or some other discharge. Another definition, but not so perspicuous or correct, is, that it is a chasm formed on the surface of the body by the removal of parts back into the system by the action of absorbents; and a third is, a granulating surface secreting matter, the last of which is most satisfactory. The ulcer consequent on an acute abscess occurring in a healthy constitution, is named a healthy ulcer, from its being a process of nature to repair the breach of continuity, but the same is applicable to the syphilitic ulcer. Simple, consequently, is a better appellation than healthy to this kind of ulcer, as no diseased action can be said to be healthy. It is termed the 'simple purulent ulcer;' and 'ulcers in parts which have sufficient strength to carry on the actions necessary for their recovery.' In the *Philosophical Transactions* for 1819, Sir E. Home has detailed some most ingenious microscopical observations on the conversion of pus into granulations, by the extrication of carbonic acid gas from coagulated pus, forming tubes or canals, which are filled with red blood, and thus connected with the circulation: this, however, appears too chemical a process. In this species of ulcer, the granulations are bright red conical points, regularly formed, numerous, firm and distinct; and the matter secreted by them is pus in a moderate quantity. These granulations, when they arrive at the level of the skin, form a thin film or skin, which begins at the edge, if the structure of the skin has been destroyed, and spreads over the sore, and in the middle, or all over the sore, if the cutaneous tissue is preserved, as is beautifully exemplified in the ulceration supervening to a gentle scald. The treatment of this simple ulcer is merely to absorb the pus, and afford support to the edges and the cutaneous circulation; dry lint, therefore, is often preferable to that spread with simple ointment, and should be notched towards the centre in order to give exit to the pus. For the same reason a pledget or compress of tow should be put over it, and a roller gently applied above. The great art in the treatment of this ulcer is not to stimulate it, and to preserve the new skin when formed. On renewing the dressings, the old should be thoroughly softened with warm water before removal. When the ulcer occurs in the leg, which, from its exposed and depending situation, is most subject to ulcers, the roller should be applied from the toes to the groin, as exemplified in fig. 1, of Plate DXVI: and the patient should keep as much as possible in the horizontal position. Various substances are used for bandages, as calico, linen, and flannel.

This simple or healthy ulcer is very easily inflamed or irritated, and then assumes the name of the irritable ulcer, or the 'inflamed ulcer,' or 'ulcers in parts whose actions are too violent to form healthy granulations, whether this arises from the state of the parts or of the constitution,' and is characterized by the sore becoming hot and painful, and the granulations of a dark red colour, approaching to purple, very small, and scarcely distinguishable, the edges of the sore thin, ulcerated, or phagedenic, having a worm-eaten appearance, and the skin around the ulcer inflamed, of a dark purple colour. The secretion is thin, and either bloody, dirty white, or of a green colour; and is so acrid as to excoriate the surrounding skin, and even the granulations themselves. The surface of the sore is occasionally of a brown instead of a purple colour, while at other times white or ash-coloured; and there are frequently irregular elevations and depressions, as if they were excavated by the matter. This species of ulcer is easily produced by the most trifling exciting cause. The treatment of this irritable ulcer is by the application of large anodyne fomentations and poultices, low diet, and absolute rest in the horizontal position, until the inflammatory action is completely subdued, which is indicated by the absence of the pain, and the diminution of the inflamed colour of the surrounding skin; by the edges becoming defined and clean; by the sore becoming more florid in colour, and by the secretion becoming creamy and purulent; or, in other words, by the sore presenting the characters of the simple ulcer. For the first two or three days simple ointment should be used, and a roller applied. The diet and exercise ought to be slowly increased.

Both this irritable and the simple ulcer are very liable to become stationary in the process of healing, and ultimately to be so indolent as to have no disposition to advance; it is then termed an 'indolent or callous ulcer,' which is characterized by the edges being thick, smooth, callous, and of a blue white colour, and by the surface of the sore being below the level of the callous margin, and presenting a smooth, glistening, flabby appearance, there being few or no granulations, and those which do exist, generally pale and languid. The discharge is frequently thin, profuse and viscid, adhering to the ulcer; but sometimes it is scanty, and then the surface of the ulcer is of a brown colour. The skin around is purple and hardened, but not inflamed, particularly if the ulcer has been of any standing; the cautaneous veins are commonly varicose. The bluish white colour of the edges is the most characteristic sign of this species of ulcer. This ulcer occurs, like many others, most frequently on the leg, and generally in advanced life; from the age of maturity, however, all are subject to this disease, which is most prevalent in the labouring classes, and among soldiers and sailors. Its treatment consists in gently and gradually stimulating the parts to action, by the application of a solution of the sulphate of copper, and of a mild ointment of the red oxide of mercury, together with a firm compress and bandage. The judicious arrangement of compresses adopted by Mr. Whately, is particularly applicable to this ulcer. When this solution, and the ointment of the red oxide, lose their stimulating qualities, an event which occurs in all local applications, they must be strengthened gradually and cautiously; and when the ointment has been increased to the strength of ʒij to ʒi of lard; the unguentum resinosum should be substituted for the lard. The patient should be allowed nourishing diet, and even stimulating food, and should keep the leg quiet, in the horizontal attitude. Mercury and cantharides are most powerful auxiliaries, if administered only to excite the system to greater activity. Such a numerous catalogue of remedies are recommended for this ulcer, that John Bell has humorously classified them into innocent drugs, humerous drugs, and devilish drugs. The most common in use are adhesive plaster, ointment of the nitrate of mercury, hot dressings, which consist of resinous ointment and oil of turpentine rendered hot, ardent spirits, solutions of nitrate of silver, nitrate of copper, muriate of mercury, oxide of arsenic, tincture of myrrh, lemon juice, and the gastric juice of ruminating animals. Of these the adhesive plaster is the most valuable, and should be cut into slips of from one to two inches in breadth, and of such a length as to extend some inches on each side of the ulcer, but never so long as to encircle the leg, since it then interrupts the circulation of the skin, unless the roller is applied tight enough to support the cutaneous circulation distad to the adhesive strapping. The slips or straps are applied across the sore, previously heating them gently by drawing the back of the plaster along the surface of a smoothing iron. The lowest or distad one should be first put on, by fixing its one extremity to the sound skin on the one side of the ulcer, where it ought to be retained by the hand of the patient, and pulling it across, while with the fingers of the left hand, the opposite sides of the sore ought to be approximated as much as possible, before applying the other extremity of the strap to the sound skin, because the intention is to bind or approximate the edges by force. As many straps should be used as to extend fully one inch at each extreme of the ulcer, and not overlap each other, but rather to have a small gap between each, to allow the matter to exude. Over the adhesive straps, a compress of tow, and lastly, a bandage are used. The ointment of the red oxide of mercury is preferable to the nitrate. Warm dressings are a powerful remedy, but difficult to manage. Ardent spirits and tincture of myrrh are beneficial. The nitrates of silver, copper, the muriate of mercury, and oxide of arsenic are escharotics, and not stimulants like the sulphate of copper, therefore inadmissible in this species of ulcer. The sulphate of copper never acts as an escharotic, even in its crude state, but always as a stimulant; and it is only when strong compression is combined with its application, that it appears to act as an escharotic, but in reality only as a powerful absorbent. The lemon juice is a good application, and so also is the gastric juice of ruminating animals. The bluish white callous border ought never to be excised with a knife, or destroyed with caustic, as it is the newly formed skin sparingly supplied with blood vessels. This callous margin indicates want of action, and is the most favourable for the application of the adhesive strap.

This indolent ulcer, the most generally met with in practice, is frequently healing in one part, while inflamed and phagedenic in another, apparently from the extent of surface involved; as it sometimes extends from the knee to the ankle joint; and in this case, the inflammatory and phagedenic disposition must be thoroughly subdued by fomentations, poultices, rest, and low diet, before any attempt to heal the callous portion; and even when this irritable disposition has been removed, caution must be observed before we have recourse to exciting treatment, so that simple dressings may be advantageously applied for two or three days. The same inflamed and phagedenic action is also liable to attack this ulcer while under treatment, when the same means must be adopted. The securing of the saphena major vein with a ligature, as practised by Paré, Wiseman, and Sir E. Home, is now abandoned in consequence of the inflammation which is sometimes induced; but this vein, in all cases where it is varicose, should be obliterated with the potassa above the seat of the ulcer.

The fungous ulcer is merely the simple ulcer which has arrived at the level of the skin, and instead of cicatrizing, shoots forth luxuriant granulations, which become pale and flabby, and in common language termed proud flesh, when the sore is of small magnitude. Neither the irritable nor the callous ulcer can produce these exuberant growths, for in the former there is too much action, which checks their production, and in the latter the action is defective. These granulations are found in ulcers occurring in the venereal and scrofulous constitutions, as well as in the cancerous and carious ulcers; and in the latter these fungous excrescences are best exemplified. The treatment consists in reducing the exuberant granulations by the nitrates of silver or copper, to the level of the skin, when they generally cicatrize.

By the Phagedenic ulcer, is generally considered Gangrena Phagedena, or hospital gangrene, but there is a phagedenic ulcer destitute of a sloughing or mortifying disposition, although it eats away to a horrible extent, being derived from φαγω *to eat:* it is termed by Sir A. Cooper, the gangrenous or sloughing ulcer. It occurs commonly after an ulcer has been neglected or suffered to remain too long open, and not unfrequently in the syphilitic constitution. It is characterized by irregular knotted edges, which are smooth and flat on one side, and on the other high and rugged: by its healing in some points, and spreading rapidly in others, but still advancing in extent as a whole; the surface also sometimes looks well, and at others ill-conditioned; the discharge is occasionally purulent, at other times thin and ichorous, and sometimes so profuse as to induce hectic fever; the skin around is purple and violaceous, and more so where it is phagedenic; the pain is very acute, and at times quite insufferable; the inflammatory action is more frequently chronic than acute, becoming acute only occasionally, from some source of irritation. This ulcer attacks the integuments of the legs, the labia of the female; the penis, the scrotum and nates of the male. The treatment consists in subduing all irritation and inflammation by anodyne fomentations and poultices, low diet and absolute rest; then the application of weak escharotic solutions, together with a weak ointment of the red oxide of mercury; these should be changed or increased in strength, whenever they appear to lose their effect. Not unfrequently they produce too much irritation, and require to be given up, and to have substituted the fomentations and poultices. The chief object to be observed in this ulceration, is to endeavour to arrest its progress, and to change it from this inveterate species to the simple ulcer. Nothing is so beneficial in the treatment of this and all inveterate ulcers as change of air. The diet should be mild, consisting of vegetables and fruits, together with poultry, eggs and milk, and the decoction of sarsaparilla with the compound calomel pill may be given. This ulcer may be termed the simple phagedenic ulcer.

There is an ulcer which precisely resembles this phagedenic sore in appearance, for they ought to be considered one, being purely phagedenic, but which only attacks the face, and from its supposed contagious nature is named *Noli me Tangere*; and is classed by authors under the herpetic ulcer. It generally begins at the alæ of the nose, but not unfrequently in the upper and even the lower lip, also in the forehead or angle of the eye, hence no part of the face is exempt from its first attack, and spreads upwards, downwards, and centrad, until it ultimately removes the whole countenance, producing hectic fever, and repeated hemorrhagies, when death closes the scene. Its characters are identically the same as the phagedenic ulcer last described, and need not therefore be repeated. The ulceration however is preceded by a yellow pustular or scabby eruption, surrounded by a violet-coloured circumscribed inflammation. These moist yellow spots either fall off, or are picked off by the patient, and expose this ulceration, discharging at that time a thin serous acrid matter. When the inflammation is moderate, there is commonly little pain, but when severe, there is an acute burning pain, and more or less concomitant fever. It is a most inveterate ulceration, and unless treated in its earlier stages, often foils the labours of the surgeon. The treatment should be the same as that recommended for the simple phagedenic ulcer; but if it does not succeed in curing it, the chloride of lime very much diluted may be tried. The following ointment sometimes produces beneficial effects, ʒss of camphor, ʒiij of the white precipitate of mercury, ℥iss of the prepared carbonate of lime, and ℥ij of lard finely levigated. If after all, the ulceration continues inveterate, the whole base should be excised if practicable, and if not, destroyed or eaten away with the crude nitrate of copper. Some use equal parts of alum and chalk to the edges in order to destroy the diseased structure. A number of authors consider this disease constitutional, and recommend arsenic, antimonials, mercury, purgatives, and sudorifics internally, with vegetable diet and warm baths. There does not appear however the least ground for considering it constitutional, as it begins locally and continues so nearly to the conclusion of the horrid scene. What seems to have deceived us on this subject is, that all ulcers heal from the powers of the constitution, consequently when these are too vigorous or too languid, the healing process does not take place. The constitution, as well as the ulcer, requires to be sound or healthy.

Tinea capitis is also classed under this ulcer, and is a variety of the herpetic or creeping ulceration. Tinea capitis, porrigo, or scald head, consists of six species, according to Bateman, but we shall limit ourselves to two, the porrigo furfurans, and the porrigo scutulata. Porrigo furfurans, or tinea capitis, begins with an eruption of small achores, the excoriation is slight, and the discharge concretes and falls off in innumerable thin laminated scabs. Fresh pustules arise and follow the same course, until the greater part of the scalp of the head is involved. The hair partly falls off, and there is intolerable itching and soreness. This affection commonly begins in early life from inattention to cleanliness, and a peculiar prejudice of the parent against washing the head of the child. The treatment consists in removing the whole hair of the head with a razor, applying a large quantity of resinous ointment at bed time, in order to soften the attachments of the crusts, which, on the following morning, are to be washed off with soft brown soap and warm water. The ulceration is then to be treated with the same escharotic lotions and ointment, as recommended under the simple phagedenic ulcer. Pure nitrate of silver is the most prompt remedy. This ulceration is also considered constitutional, and even infectious by many authors; but it can be no more constitutional than *noli me tangere*, and to consider it infectious appears truly ludicrous; but its contagious character is completely established. In the application of escharotics to the scalp, we must attend to their stimulating effects upon the brain. Porrigo scutulata, or herpes circinatus, or ringworm, attacks the scalp, face, and neck, in the form of separate patches, of an irregular circular shape, resembling the fairy rings made by some of the fungi, from which it derives its name. It begins with clusters of small light yellow pustules, which soon break and form scabs or scales, beneath which a delicate ulceration is perceptible. When neglected, it spreads all over the head in the form of clustered patches. The treatment is precisely the same as that for tinea capitis, and is frequently as obstinate to cure. A variety of remedies are recommended by authors for both of these ulcerations.

Gangrenous phagedenic ulcer, or hospital gangrene, named also malignant ulcer, putrid ulcer, sloughing sore, contagious gangrene, phagedena gangrenosa, gangrene humide des hopitaux, and pourriture d'hopital. It is divided by some authors into two, and by others into four varieties, which is evidently superfluous. This ulceration attacks all kinds of ulcers, wounds, and even blistered surfaces, in hospitals, ships, and in low crowded filthy situations; and the smaller the sore, the more liable is it to be affected. The ulcer or wound becomes covered with a dirty white coloured slough, or a tenacious viscid ash-coloured matter, the secretion being checked; the edges are surrounded with an erysipelatous blush, and more or less œdema. The patient feels little pain in the sore, which has more the sensation of a sting from a gnat; he is attacked with rigors, has a foul tongue, loaded constipated bowels, and excessive thirst, which soon form active fever. On the following day probably, the ulcer has sloughed all round, and may be double, or even quadruple, its original size, and in a few days becomes of such magnitude as to endanger his life. The edges and base of the ulcer slough with alarming rapidity, the former becoming hardened, ragged, and everted, and having a most irregular shape, while the latter or granulations are large, tumid, and distended with gas. Small dark coloured vesicles appear on the sound skin surrounding the ulcer, which burst, and also form sloughing sores ultimately communicating with the original. The discharge is sanious, ichorous, viscid, emitting a peculiarly offensive odour. The patient now suffers continually from burning, lancinating pains. Fresh flabby blackish sloughs are rapidly formed, which overtop the ragged inflamed edges that are immediately involved, until such an extent of ulceration is produced, as either to expose a number of blood-vessels, usually veins, which by repeated bleedings exhaust the patient, or the ulceration carries him off by the debility consequent on so great a source of irritation, or he dies of diarrhœa or hectic fever. Blood-vessels, particularly large arteries, do not generally yield so soon to this frightful ulceration as other textures. This ulcer is described to have occurred spontaneously; but it seems very doubtful if this ever occurs, for it is more probable that some source of irritation existed, as the pulling out of a hair of the skin, or the prick of a pin. Some authors contend that the febrile affection always precedes the ulceration, and if by this is meant, that a patient while affected with a simple ulcer or scratch is attacked with fever, which from the nature of the atmosphere, and the state of his constitution, assumes a very violent type, and readily disposes this trifling ulcer to acquire this gangrenous character, it is no doubt correct, as is satisfactorily proved by the cases of Blackadder. The lymphatic glands of the groin or axilla, whichever extremity is affected, are generally excited early, and sometimes suppurate, and assume this phagedenic ulceration: while at other times they suppurate and heal kindly, while on other occasions again they merely become swollen. During this suppurative and healing process, they suspend the phagedenic disposition of the original ulcer. By some authors it is stated that the syphilitic, cancerous, scrofulous, and variolous ulcers are not liable to be attacked with phagedena, an error very satisfactorily confuted by Drs. Thomson and Hennen. The treatment of this formidable disease, is by the vigorous use of the lancet in the beginning or inflammatory stage, and by repeating it as often as any inflammatory diathesis remains. The inflammatory action does not last long, in consequence of the great debilitating causes present; still, if we do not bleed during the inflammatory stage, the fever will continue to rage, and the ulceration will be the more extensive, and consequently the debility greater, which is clearly and satisfactorily proved by the various cases on record, and is daily evinced in the treatment of continued and typhus fevers. The propriety of blood-letting is supported by Drs. Trotter, Hennen, and Boggie. The application of the actual cautery to the ulcer, followed by hot dressings, and over these dry lint, tow, and the most gentle bandaging. What is termed the eighteen tailed bandage (see Plate DXV. Fig. 4), deserves to be preferred in such cases. The ulcer should be divested as much as possible of sloughs and moisture, previously to the application of the cautery, which should then be applied to every point, particularly the edges, and be repeated whenever there is the least tendency of the ulcer to spread. The actual cautery and compression are the only remedies for ulcerated arteries, as they will not bear the ligature, however remote from the diseased action, and a fresh wound would instantaneously assume the gangrenous action. The hot dressings should be applied as hot as the patient can bear them, and be removed whenever they are moistened with matter, which commonly occurs twice or thrice a day; and the sore at each renewal ought to be washed with a warm solution of the subcarbonate of potash. No sponge should be employed, but lint and tow substituted, which ought to be immediately burned, as cleanliness is of vital importance in the treatment. The bandages after being thoroughly washed, ought to be immersed in lime-water for some hours, a practice of very beneficial consequence in hospitals. In the inflammatory stage the patient should be put into a hot bath once or twice a day, or the vapour-bath can be administered in bed, or he can be sponged with hot water. If possible, his linens and bedclothes ought to be changed daily, and the most free ventilation permitted. His diet during the inflammatory stage should be mild, and consist chiefly of ripe fruits and succulent vegetables, if the season permits. Great debility is necessarily to be anticipated: therefore, whenever all inflammatory diathesis has been subdued, the diet must be rendered nourishing, with a liberal allowance of wine and porter, if the bowels are not relaxed. Large opiates and the sulphate of quinine should be given. Hospital gangrene is peculiarly liable to relapse, on which account the greatest attention should be paid to the patient until the wound or ulcer has completely cicatrized, and he is restored to perfect health. An extraordinary variety of remedies have been used in this ulceration, the most efficacious of which are, the concentrated or diluted mineral acids, the nitrates of copper or silver, or solutions of these, also the solutio arsenicalis. Amputation is inadmissible in this species of gangrene, in consequence of the violent inflammatory fever present, which makes it a case of mortification arising from an internal cause. The daring and convincing experiments of Dr. Blackadder, and the narrative of Dr. Trotter, satisfactorily establish that it is not infectious, but its contagious nature cannot be disputed.

Scorbutic ulcer is now rarely met with; it begins with lassitude, indigestion, bleeding of the gums on the least touch, and roughness of the skin resembling that of the goose. The muscles become rigid, the gums spongy, effusions of blood take place in different parts of the body, frequently under the skin in the form of large livid blotches like ecchymosis, and generally on the lower extremities; and the slightest bruise produces a tumour containing effused blood, which is very liable to ulcerate. The legs become œdematous, the face presents a livid bloated appearance; he is early attacked with diarrhœa, which is often accompanied with blood, hemorrhage being either spontaneous or arising from the most trifling injury. The least degree of exertion produces laborious breathing, and any attempt to raise himself to the erect posture is liable to produce fainting and even death. If the individual has been formerly affected with ulcers, these break out again, and if he has had a fractured bone, the union dissolves and the ends separate. Ulcers also occur spontaneously, and one and all are characterized by livid edges, which are puffed up by luxuriant fleshy excrescences under the skin, by want of granulations, the flesh at the bottom of the ulcer presenting a dark grumous appearance, soft and spongy, and generally covered with cakes of coagulated blood, which adhere so closely as to be with difficulty wiped off. The discharge is thin, fetid, and mingled with blood. As the ulcer advances, a soft bloody fungus shoots forth, which acquires in twelve hours an enormous size, and even when removed with the knife, is as quickly regenerated. This was compared to the liver of the bullock by the sailors of Anson and Cook. Scurvy is produced by living solely on animal diet.

The treatment of this disease consists in the internal use of fresh fruits and vegetables, particularly of such fruits as have the citric acid, and those vegetables which are acid and succulent, as in the class Tetradynamia; also the alliaceous plants in the class Hexandria. Porter and spruce beer are beneficial remedies. The patient should be in a large well-aired apartment, and have plenty of fresh air, remain constantly in the horizontal attitude, taking his food out of a cream-jug or tea-pot, and using a bed-pan and urinal, when the calls of nature occur. The ulcer is to be treated with lime or lemon-juice and gentle bandaging, but the chief object is to change this peculiar diathesis to one of health, and then the ulcer soon heals, and even disunited bones are again consolidated.

When the syphilitic ulcer has been imprudently treated with mercury, without science or system, it inflames, becomes irritable and phagedenic, and is then named the mercurial ulcer; it has irregular hard edges, a deep sloughing base, a dark coloured inflammation around; is apparently healing in one part having a delicate pellicle, while it is increasing rapidity in another. Its treatment consists in applying to the ulcer opiate fomentations and poultices, giving up the mercury; in abstracting blood from the system if it can bear it, giving large doses of the sulphate of magnesia, small doses of sulphur, frequently repeated, the use of the warm bath, and avoiding every exertion.

The other ulcers, the syphilitic, scrofulous, &c. are treated of, under the diseases to which they belong, and for which the reader is referred to the Article Medicine.

Chilblains is that kind of phlegmonous inflammation which attacks the fingers, toes, and heels, and occasionally the nose, lips, and ears in cold weather, particularly of those leading a sedentary life, and women more frequently than men, and children oftener than adults. The parts affected are swollen, of a purple colour, hot and painful, and not unfrequently suppurate, and even mortify. Small serous vesicles often appear, which burst, and become fretful, troublesome ulcers. These occasionally penetrate to the bone, and discharge a thin ichorous or sanious matter, producing caries, which ultimately requires amputation of the limb. These ulcers are sometimes covered with sloughs, or the inflamed part at once ends in gangrene, and then sloughs. Chilblains should be treated, in the inflammatory stage, like phlegmon; during the suppurative, as acute abscess; and while in the ulcerative stage, the same as the irritable, simple, or callous ulcer, according to appearances; and when gangrene occurs, the same treatment as that detailed under mortification should be adopted; and if caries supervenes, the same remedies employed as recommended under that disease of the bones. When chilblains have been cured, the parts should be rubbed with rubefacients, kept warm, and in as frequent motion as possible, as they are very liable to recur. In surgical works, the most heterogeneous medley of remedies is given.

Furunculus or boil, a species of phlegmon, is an exceedingly hot and painful inflammatory tumour, about the size of a pigeon's egg, circumscribed, hard, prominent, of a purple colour, and of a conical shape. A white or occasionally livid pustule soon forms on its apex, but the tumour suppurates slowly, secreting only a small quantity of matter mixed with blood; the greater proportion of it becoming gangrenous, and forming a firm slough or core, as it is named in common language, which is dead cellular substance. If left to itself, this tumour is very slow of bursting and discharging the slough, and there remains a deep cavity, with a circumscribed hard base, which continues to discharge the same bloody matter, and is very long of healing. When there are two or more boils at once, which is no uncommon occurrence, there is more or less symptomatic fever; and they also frequently occur in succession. They generally take place in loose cellular tissue, as that on the nates and back part of the thighs, occurring commonly about puberty, and in the spring, apparently from the excitement given to the constitution at this period of the year, and when the system is undergoing those changes peculiar to that time of life The treatment of this tumour, during its inflammatory stage, is the same as that for phlegmon, and when suppuration has taken place, by a crucial incision. The treatment for the ulcerative stage, is the same as that recommended for ulcers, whether of the irritable, simple, or callous types. The slough is very tardy in being thrown off, and requires hot dressings. To prevent the recurrence of boils, the diet should be mild and nutritive, the bowels attended to, and the patient take plenty of exercise in the open air.

Anthrax or carbuncle, another species of phlegmon, is merely an aggravated or more violent species of furunculus, and is an extensive, flat, hard tumour, of a dark purple colour, darker in the centre than at the circumference, and feeling very deeply seated. It commonly occurs on the back between the shoulders, and begins with great heat and acute pain, a diffused tumefaction, followed early by a small itching pimple, which soon becomes a vesicle or blister, and bursts, discharging a thin brown or bloody sanies, followed by the appearance of a yellow coloured slough. Sometimes several pimples are produced by the patient scratching the surface, which becomes intolerably itchy, while on other occasions several vesicles occur, which spontaneously burst, and discharge the same bloody sanies. When the disease is left to itself, these apertures slowly ulcerate, and run into one another, exposing to view an extensive slough, which, when thrown off, leaves a large ulcerous cavity, discharging bloody sanies. Whenever a carbuncle begins, it should be freely leeched or scarified, large anodyne poultices or fomentations applied, and as soon as suppuration takes place, it ought to be divided by a crucial incision, and the poultices then should have turpentine, resinous ointment, or camphorated oil mixed with them, and continued until the slough is discharged, when it should be treated with charpie, moistened with turpentine or other stimulants, as it is very indolent, and removing portions of it from time to time as they become loose.

Chronic inflammation is that inflammatory action which continues for a long period, so slow, mild and passive, as sometimes to be imperceptible, and considered by some authors as not to exist on many occasions. The most palpable example is that which follows an acute attack of inflammation of the eye, this organ continuing for months and even years, red, fretful, and weak, but not painful, hot, and fiery; all acute inflammatory attacks are liable to become chronic; but there is a chronic state of inflammation which begins *a priori*, as, for example, that which precedes lumbar and other chronic abscesses, and also the formation of tumours. In superficial chronic abscess, there is occasionally tumefaction, which is circumscribed and hard, but attended with as little pain as in the deep seated abscess. In both there is commonly constitutional derangement, and they generally occur in a feeble frame of the scrofulous diathesis. In the progress of this disease the local symptoms of inflammation become more manifest, and still more so in the latter stages. This species of inflammation generally attacks serous and mucous surfaces, although every structure may become the seat of it. Bursæ mucosæ, as that under the deltoid or glutæus maximus muscles are very often attacked, and so also is the synovial membrane of the knee-joint.

The treatment of chronic inflammation, when it attacks an exposed surface as the eye, or accompanies an ulcer, is by stimulant lotions and ointments. The diet should be chiefly farinaceous, bowels attended to, the eyes kept from a bright light, and little or no exercise allowed; when it attacks a mucous canal, as the urethra, by the same stimulant lotions still more cautiously used, and the same diet, with perfect rest in the horizontal posture. When it attacks a deep-seated structure, such as the bursa of the deltoid, the application of leeches or the scarificator is necessary, the latter, however, deserves to be preferred, in consequence of the external irritation excited; these, together with low diet, gentle laxatives and perfect rest, may prevent suppuration; but they generally require to be followed by the moxa. In deep-seated chronic inflammation, the moxa appears to act by inducing counter-irritation or counter-inflammation, which removes the action of the inflamed vessels from the disease to itself, and also excites active absorption. On these grounds, the more quickly the ulceration produced by the moxa heals, so as to enable another to be applied, the better, and hence, small but deep eschars made by moxas are better than large ones. The practice, therefore, of keeping issues open is now nearly obsolete.

Chronic abscess is the cyst or sac of matter resulting from chronic inflammation, and occurs often in the abdominal muscles, particularly in the psoas magnus, and is then termed psoas or lumbar abscess. This species of abscess attacks likewise the ovarium, and indeed every kind of structure. It affects every age and constitution, but more frequently early life, and the scrofulous habit, in consequence of debility. We are seldom aware of the existence of chronic abscess until the matter has been actually secreted, when it ought to be evacuated in the following manner. The skin is to be pulled upwards or aside, that it may act afterwards as a valve, when a small oblique aperture is to be made with the bistoury, and a silver probe inserted in the wound, and the matter evacuated, which is thin, serous, and mixed with curdly flakes, but sometimes purulent. The wound is to be immediately closed with adhesive plaster, and healed by the first intention. During the treatment of chronic abscess, the diet ought to be mild and nourishing, the patient as much as possible in the open air, if dry and temperate, and if the seat of the disease will permit it; and he should take sulphate of quinine, or some of the preparations of iron or diluted sulphuric acid. When the psoas muscle is affected, he will require to be drawn in an easy hung carriage. Tepid and ultimately cold bathing, or sponging, with friction, are powerful auxiliaries. Whenever matter has again collected, however small in quantity, it ought to be discharged. The above treatment must vary considerably according to the seat of the disease.

In lumbar or psoas abscess, the disease begins in the lumbar vertebræ, which ulcerate and become carious, and the matter secreted either gravitates in the course of the muscle, being confined by its fibres or fascia, forming a tube, or proceeds directly dorsad to the integuments of the loins. If it is confined by the fascia of the muscle, the matter sometimes gravitates to the groin, and presents itself either below or above Poupart's ligament, near the anterior superior spinous process of the os ilium, or near the pubes; sometimes it emerges at the crural aperture and descends below or centrad of the fascia lata to the poples, and even retrogrades upwards or proximad to the tuberosity of the os ischium; at other times it gravitates into the pelvic cavity, emerges at the great sacro-ischiatic notch, and makes its appearance near the anus. In rare instances, the matter descends along both psoæ muscles, forming two abscesses or a double abscess. Whenever the matter advances to the integuments or points, the skin at first is not discoloured, but an impulse is given to the fluctuation on coughing, and in a few days the skin becomes discoloured, inflames, ulcerates, and ruptures. The symptoms indicating this affection are remarkably insidious, being seldom apparent until the abscess points. The patient complains of weakness and uneasiness in the region of the loins, which are much aggravated on ascending a stair, and he is easily fatigued with walking. Occasionally there is felt considerable pain in the loins, which seems to follow acute inflammation of the vertebræ; and not unfrequently there is distortion of the spine. As lumbar abscess is liable to be confounded with hernia and fungus hæmatodes, we must be careful in our diagnosis before opening it. The history of the case, together with the fluctuation of the tumour, which is tense in the erect, and nearly disappears in the horizontal posture, becoming softer, flatter, and looser; and when again placed in the erect attitude, by the impossibility of preventing the descent of the matter, lumbar abscess is characterized. The treatment has been already described, with the exception of the injection of lime water. Lumbar abscess attacks youth, and the male more frequently than the female; however, Mr. Abernethy cites more cases of its occurring between twenty and forty years of age, than at an earlier period.

Hectic fever, which particularly accompanies chronic abscess when opened, is characterized by the following symptoms. The patient begins to have a hot skin, especially in the palms of the hands and soles of the feet, a crimson blush on the cheeks, small quick pulse, loss of appetite, thirst, nocturnal perspirations, lateritious sediment in his urine and diarrhœa. There are exacerbations in the evening, there being a chilly, a hot, and a perspirative stage in succession like in intermittent fever. This is supposed by some authors to depend on the absorption of the matter, but no hectic fever takes place until the matter is evacuated; by others to depend on the irritation together with the increased discharge, but in some cases of phthysis pulmonalis, where the individual wastes away without the slightest irritation or pain, hectic fever accompanies the disease almost from the beginning; by others again, to be the consequence of a change in the system, induced by the process of suppuration, or even of the previous inflammatory action that gives rise to this process. It appears rather to be consequent on mere debility of constitution, which whenever it is so far exhausted from a discharge in any disease, that the nervous and circulating systems have not their accustomed supply of nutriment, *i. e.* the blood, then increased absorption goes on with great rapidity, while there is no nutrition, the nutritive lymph being removed by the discharge. The hectic fever which accompanies Nostalgia corroborates this view. Its treatment consists in light nutritive diet, diluted sulphuric acid, and the cretaceous or catechu mixture, when the bowels are affected, attending at the same time to the local affection producing it.

Mortification is one of the common terminations of inflammation, and occurs when the inflammatory action is so extremely violent as to destroy the structure of the nerves, arteries, veins, and contiguous textures, which are overpowered by exhaustion; while the contiguous tissues are destroyed both by inflammatory action and by being gorged with blood, which coagulates in consequence of not being kept in motion. This is usually denominated acute gangrene, also inflammatory or humid gangrene. Gangrene is confined to that degree of mortification where sensibility, motion, and warmth are present: but when these phenomena cease, and the part assumes a livid, brown or black colour, it is then termed sphacelus or complete mortification. Etymologically, these terms do not admit of this explanation, gangrene being derived from γαινα, *to feed upon*, and sphacelus from σφαζω, *to destroy*. Some authors use both terms synonymously, while others consider that sphacelus should be applied only to mortification extending to the bones. Mortification thus dependent on a severe degree of inflammatory action, is originally produced by chemical or mechanical stimuli. When the urethra or urinary bladder is injured, and the urine escapes into the cellular tissue of the perineum or scrotum, gangrene is frequently the result; and this also occurs when any of the abdominal viscera are forced out of their cavity and strangulated. Gangrene likewise takes place from the eating of cock-spur rye, the ossification of arteries, tumours impeding the return of the circulation of the blood, diseased condition of the arteries or veins producing coagulation of the blood in their cavities, and from ligatures applied to the trunks of arteries or veins. Of the two varieties of inflammation, mortification is more liable to supervene to the erysipelatous, and still more so to their combination or erysipelas phlegmonodes, and although all textures when inflamed do sometimes mortify, yet the most compact, such as bone, skin, stomach and intestines, are the most prone to it, because their blood-vessels have not room to form ulcerative papillæ; and the arteries are found to possess the greatest power of resisting mortification.

When a part highly inflamed is on the verge of becoming gangrenous, the pain is violently increased, the colour becomes deeper and extends farther, the tumefaction increases from the effusion of serum, communicating a doughy feeling, the cuticle is raised up into blisters, and the part appears erysipelatous. The pulse at this period is small and rapid, the tongue brown and crusted, and every symptom of typhus fever. This may be considered the gangrenous stage, which if not arrested ends rapidly in sphacelus. The pain and sensibility then cease, the part becomes œdematous, emphysematous, cold, black, and fetid; a profuse watery and dirty-coloured discharge is poured out, the pulse scarcely perceptible, the accompanying fever having as it were ceased, which often takes place suddenly and carries off the patient; but a low typhoid fever more frequently continues for some days, attended with hiccup, subsultus tendinum, low delirium, and diarrhœa. This typhoid fever is supposed by some to arise from the absorption of the fetid matter, but as typhus supervenes to synochus or synocha, if severe and of long duration, we are entitled to ascribe it in this case to the same cause, viz. the violence of the inflammatory fever.

The treatment of the gangrenous or first stage is by applying large anodyne poultices in the hope of subduing the inflammatory action still present, and which is the cause of the gangrene; by keeping the patient quiet, on low diet, and administering purgatives. The constitution is generally too exhausted to bear general blood-letting, but leeches or cupping may be applied to the part. A large opiate should be given at bed-time. Should the part sphacelate, the yest or charcoal poultice should be used, or hot dressings applied, and the strength of the patient supported with beef-tea, animal jellies, and wine, together with the opiate at bed time. If the mortified part is to recover by sphacelation, a red line appears on the sound skin at the point of separation, between the living and the dead portions, which line denotes the adhesive inflammation, soon forming the ulcerative, which producing suppurative papillæ or granulations, secrete purulent matter, so that the whole forms an ulcerated surface. Consequently, in a limb which sphacelates, no hemorrhage takes place; a circumstance also dependent on the arteries being plugged up with coagula of blood.

Whenever the sphacelated parts have been thrown off and ulceration fairly established, the part should be dressed as a simple ulcer. The sphacelated portions may be cut away with scissors or scalped at each dressing.

In cases of mortification occurring from mechanical causes, as severe contusions, or traumatic gangrene, amputation may be with safety performed at any period; but in mortification arising from constitutional causes, as a general diseased condition of the arteries or veins, amputation proves fatal.

Mortification occurs occasionally from excessive cold. Acute pain is experienced in the part affected, with numbness, weight, and a tingling sensation in the legs; the feet of an obscure red colour, and slightly swollen. Sometimes a light red is perceptible at the base of the toes and patellar aspect of the foot; at others, they are deprived of motion, sensibility and heat, and appear black and withered. The treatment is by applying snow or ice cold water to the part in order to thaw it, then camphorated spirit of wine or poultices. When the mortification is superficial, the dead parts commonly separate between the ninth and thirteenth day, and leave an ulcerated surface, which requires the same treatment as ulcers. When a whole limb is affected with mortification, a slow typhoid fever, accompanied with diarrhœa carries off the patient; or the grangrenous portion becomes bounded by the circular line of adhesive inflammation, which suppurates and throws off the mass. Amputation in such cases should be resorted to, for it is mortification from an external cause, the same as that from an external contusion. The operation ought to be deferred until the constitution has rallied from the benumbing effects of the cold, and the reaction of the nervous and circulating systems is fairly established. This mortification from congelation or frost-bite, and also that from ergot, is named by some surgical writers dry gangrene, and by others chronic gangrene.

The eating of ergot, or unsound or diseased rye, or mildewed wheat, has an effect on the constitution not unlike that which the living exclusively on animal food has in producing scurvy. The rye so impairs the nervous and circulating systems, that they become unable to perform their functions, consequently mortification takes place, first, in such parts of the body as are most remote from the centre of the circulation, an event that occurs in all kinds of gangrene. This variety of mortification commonly begins in the toes, which become red, painful, and hot, as if scalded with boiling water; in a few days these symptoms suddenly cease, when the toes feel cold and insensible, become dry, hard, withered, and black as charcoal. The gangrenous action now extends gradually upwards along the foot, leg, and thigh, to the trunk, and is accompanied with fever and delirium. In one instance, the lower extremities were separated at the hip joints from the trunk. This singular species of mortification has occurred chiefly in France, and become occasionally epidemic, sometimes in Switzerland, and once in England. Its treatment naturally consists in at once relinquishing the diseased rye or damaged wheat, and substituting the finest and best wheat, with nourishing diet. The gangrened parts to be treated by hot dressings, and when the sphacelated portions are separated, the ulceration to be dressed with simple ointment, dry lint, or other applications, according to the appearance of the sore. Amputation is inadmissible while the constitution is under the influence of the ergot; but afterwards, it might be necessary to form a better stump.

Mortification frequently occurs in old age, in consequence of calcareous depositions taking place in the arteries, a change of structure observed affecting those of the brain, trunk, arms, and legs, especially the last. The arteries of the lower are more subject to this affection than those of the upper extremities. In general the patient complains of great uneasiness of the foot and ankle-joint, particularly during the night, before any disease manifests itself in the toes, which then appear of a purple colour, have a cold feeling to the surgeon, while hot and painful to the patient; but in some cases only a benumbed sensation is felt for some time. The disease usually begins on the inside or tibial aspect of the little toe, and not unfrequently in both feet; from this it spreads either to the other toes or upper aspect of the foot, ankle, and even the leg; and then produces so much febrile irritation as to carry off the patient. Soon after the purple colour manifests itself, more or less tumefaction ensues, with vesication or phlyctenæ, a dark serous discharge, and a greenish black pulpy appearance of the textures affected. The treatment is by blood-letting, opiate fomentations and poultices, the internal use of opium in small doses, and frequently repeated, but never to produce delirium or impair the appetite, and by the sulphate of quinine. The diet should be light and nutritive, with a moderate allowance of wine. When the fomentations and poultices have subdued the activity of the disease, the toes may be dressed with simple ointment, and kept warm and comfortable with clothing, and on a level with the body. If any of them sphacelate, they ought to be allowed to drop off themselves, as they retain life for a longer period than sphacelated parts arising from active inflammation. This species of mortification, even if cured, is extremely liable to return, to prevent which the diet must be nutritious, with a good allowance of wine, and the feet warmly clothed, in a moderate temperature, and kept as much as possible on a level with the body.

The same peculiar mortification, characterized by simple symptoms, sometimes supervenes to a generally diseased condition of the arteries and veins, in which they become plugged up with coagula of blood interrupting the circulation. This requires the same kind of treatment as the last; and in neither is amputation admissible.

In a few cases, mortification occurs from the arterial circulation being too feeble, in consequence of some disease of the heart; and in others, from both the arterial and venous circulation being impeded by tumours growing around the aorta and vena cava.

Mortification sometimes ensues when the principal artery of a limb is secured by ligature in wounds, or in aneurism, in which case, the heel generally first affected from the pressure becomes black in colour, the cuticle vesicates, and the whole foot cold, lifeless, and of a leaden colour. The gangrene then extends rapidly along the leg, exciting excruciating pain, profuse suppuration, and hectic fever, which soon put an end to the patient's sufferings. The same result occasionally takes place when the blood, in diffused false aneurism, presses on the contiguous nerves, arteries, veins, and lymphatics, or even in circumscribed false or true aneurism from the inosculation of the smaller arteries being unable to carry on the circulation; the two last cases are, however, extremely rare. The treatment of mortification from these causes is to support the circulation by bandage and warmth; and when these fail, amputation is the only alternative. Mortification also occasionally follows gunshot wounds destroying the principal artery or vein, or artery and vein conjointly of a limb, and is evinced by a similar train of symptoms, only they advance with more rapidity, and require earlier amputation.

Mortification also occasionally occurs from long continuance in bed, in protracted fevers, in compound fracture of the bones of the thigh and leg, and from the destruction of the spinal cord in consequence of fracture of the vertebræ; in which cases, those parts of the body which sustain the greatest pressure, are affected, as in the region of the sacrum. To prevent pressure producing mortification in such cases, various contrivances are resorted to; pillows of feathers, down, distended with air, and of various shapes, are employed.

The affections of the heart have been already treated of in the Article Medicine, Vol. XIII. p. 44, and the only one admitting of a surgical operation, is dropsy of the pericardium, which, when the diagnosis is certain, is performed as follows: an incision is made between the fifth and sixth ribs between the integuments, but in such a way that the skin may afterwards act as a valve, and ought therefore to be pulled upwards. The greater pectoral and intercostal muscles are then to be cautiously divided, the operator keeping sufficiently distant from the sternum, so as to avoid the internal mammary artery. In this division of the muscles, the pleura costalis will most probably have been divided, as the pericardium will be generally found adhering to it; the latter is now seen distended with fluid, and is to be opened carefully with a lancet or bistoury, making a small aperture, when the fluid will exude. If the pericardium does not adhere to the pleura costalis, the incision in the pleura must be enlarged so as to admit the finger, which, when introduced, will feel the distended pericardium, that can then be puctured with a bistoury, guided along the finger.

A most interesting case of aneurism of the heart occurred lately, wherein a gentleman cured himself, by injecting his own respired air into the left thoracic cavity, by which he has been perfectly cured, although the symptoms were most unequivocal. He took a common ox's bladder, to the neck or mouth of which he adapted a stop-cock, and very delicate silver tube, and having filled it with his respired air, he punctured his thorax on the left side, with the silver tube, between the fifth and sixth ribs, avoiding the internal mammary and intercostal arteries, and then injected the air into his chest. This he repeated for upwards of seventy times, and several times in our presence. We have ourselves repeated it in other cases with advantage, and consider that it might be employed in other affections of the chest.

The arteries are subject to many diseases, to inflammation and its terminations, adhesion, suppuration, ulceration and gangrene; to aneurism; to the internal or serous coat being found of a deep red colour with a deposition of coagulable lymph; to a deposition of atheromatous matter, a thickened pulpy substance like steatoma, a cartilaginous matter, and a calcareous matter between their coats; they are also involved in inflammation and other diseases of contiguous structures. Of these the calcareous deposit is much the most frequent, and is the most common cause of aneurism.

Aneurism, which is derived from ανευρυνω, *to dilate*, consists of several species, the true, false, internal mixed, varicose, and aneurism by anastomosis. True aneurism, strictly speaking, is a circular or uniform dilatation of the three coats of an artery, and is commonly met with in the aorta, accompanied with thickening of the serous and muscular coats, and depositions of calcareous matter on the exterior surface of the serous, and not unfrequently atheromatous pulp between that and the muscular tunics. Some systematic writers describe two varieties of this, a circumscribed and a diffused true aneurism, which appears superfluous. A partial or lateral dilatation of the three coats of the aorta is also sometimes seen constituting another variety of true aneurism. The true aneurism of the majority of systematic writers on surgery consists in a rupture of the serous and muscular coats, with a distension of the cellular, which effect is produced by the brittleness of the serous tunic being studded with calcareous depositions, by inflammation and ulceration or mortification, by partial dilatation from debility or undue impulsion, by absorption in consequence of some diseased spot of a blackish colour and slightly inflamed, by a deposition of coagulated blood, or by a separation of the serous coat from over exertion plugging up the vessel. The first of these is found to be the most common cause. When the three coats are either at once ruptured in consequence of a wound, or by the cellular tunic in this true aneurism also bursting, and the blood is diffused in the cellular substance in the contiguity condensing it into a cyst, the disease is styled circumscribed false aneurism, to distinguish it from that in which the blood is more extensively diffused in the cellular tissue even of the muscles, and which is named diffused false aneurism. When the muscular coat only is ruptured, and the serous protruded through it, the affection is denominated internal mixed aneurism. Varicose aneurism consists in a communication being established between an artery and a vein from a wound. Aneurism by anastomosis arises from a congeries of arteries and veins forming a vascular tumour.

Aneurisms occur more frequently in men than in women, the former sex being more subject to those occurring in their extremities, the latter to those in the trunk; and in many individuals it is a constitutional disease. Aneurism occurs most commonly between thirty and forty years of age, and is said to attack the irritable, the passionate, the glutton, the drunkard, the debauched, the syphilitic, the mercurial, and the rheumatic. Coachmen, post-boys, postilions, soldiers, particularly dragoons, sailors, porters, labourers, and miners, are said to be most subject to it. These classes of individuals, by indulging in such vices, appear to dispose their arteries either to calcareous depositions or to a brittle condition, so that in the violent exertions which occur in their labours, these vessels rupture and form aneurism, in consequence of the circulation being propelled at such periods with greater force than the artery has powers of resistance; but even in the ordinary circulation of such constitutions, if an artery be weakened, it is unable to resist the momentum of the blood, and therefore, gradually yields and dilates. Violent shocks or contusions, forcible pressure on arteries, the reiterated bruising of parts, the force employed in reducing luxated joints, the violence of falls, fractures and wounds, are also causes of aneurism. The largest artery, the aorta, is most subject to this disease, the next in frequency is the femoral, and its continuation the popliteal, the third is the inguinal, the fourth the subclavian and axillary, and the fifth the carotid. The smaller series of arteries, the radial, ulnar, and tibial, are seldom attacked, with the exception of the temporal, which from being selected in arteriotomy is exceedingly subject to aneurism. The nutritious arteries of the tibia have been found affected with aneurism. The reasons of this order are very palpable, being chiefly consequent on the impetus of the blood, and the deficiency or delicacy of the adventitious tunics, together with the deficiency of support by the contiguous structures.

When true aneurism occurs in the poples, there is at first a small colourless tumour pulsating strongly, and containing only fluid blood; occasioning little or no pain, merely some irregularity of the circulation in the limb, with a spasmodic affection of the muscles, which recurs during the night and prevents sleep. On pressing the artery nearer the heart than the tumour, it is easily emptied and divested of pulsation; and on removing the pressure, the aneurismal sac is immediately filled, and the pulsation returns. Gradually as the artery dilates its powers of resistance are diminished, and the interior of the sac becomes coated with coagulated blood, which is deposited in layers or strata that thicken its walls, and render the pulsation more and more languid, and also prevent the sac from being completely emptied. Acute pain is felt in the limb, particularly below or distad to the tumour, in consequence of the pressure of the coagulated blood on the nerves, and the motion of the fluid in the sac has been compared by the patient to boiling lead. When the cellular tunic of the artery ruptures from over distension, it is converted from the true to the circumscribed false aneurism. The tumour feels now nearly solid, there being a faint pulsation opposite the aperture of the vessel, which however may point centrad, and then none is felt. When the cellular cyst forming the limits of this tumour of almost coagulated blood also ruptures, the blood escapes into the surrounding cellular tissue, diffusing itself in all directions, and forms an irregular shaped tumour, without the least pulsation, and sometimes nodulated. The pressure of the blood benumbs the nerves, impedes both the arterial and venous circulation, particularly the latter, together with that of the lymphatics, the limb consequently feels benumbed and cold, becomes œdematous, swollen, and of a leaden colour, and the joint is impeded in its motions. One or more projecting points of the tumour progressively become thinner from absorption by the pressure of the blood, or the integuments slough and ulcerate, until at last the blood hisses out, and the patient becomes exhausted from repeated hemorrhages, but never dies instantaneously. The same process takes place when aneurism occurs in the contiguity of the trachea, œsophagus, stomach, and other mucous structures: but when a serous membrane, as the pleura, forms the wall of an aneurism, it is lacerated. When a bone is pressed upon, it becomes carious. It occasionally happens that the sac increases in the direction of the artery, and presses on it beyond or distad to the tumour, and obliterates its cavity; the sac at the same time becoming entirely filled with depositions of fibrin, which extend into the artery at both ends to the nearest large branches. At other times, the tumour compresses the artery above or proximad to itself, producing adhesion of its coats with obliteration of its cavity; in other instances, this proximal portion of the vessel is plugged up with a dense compact bloody coagulum. In these cases, according to the blood effused, does absorption take place, or inflammation, suppuration and ulceration, or inflammation and gangrene; and if the patient has strength to support these events, he is cured of the aneurism, the cure being termed spontaneous.

In this gradual development of an aneurism, the trunk of the artery becomes diminished in calibre, and the flow of the blood is also rendered tardy by passing out of its course, by which means the blood is forced into the neighbouring small anastomosing branches that become enlarged. This results particularly if the artery is plugged up. In some cases, the lateral and central walls of the sac are strong enough to resist the pressure of the blood, while the integuments are too feeble, the latter therefore undergo the changes just described in the circumscribed false aneurism. Some cases of aneurism are exceedingly difficult in their diagnosis, particularly the subclavian and carotid.

The treatment of aneurism consists in general and local remedies, the former being chiefly applicable to internal aneurisms, or those situated within the cavities, the latter to external ones, or those of the extremities, neck, and external aspect of the head. The general remedies are, abstracting blood in small quantities, confining the patient to bed, and keeping him on low diet, the application of a firm compress to the tumour, with a bandage rolled from the toes equally upwards to the groin. This is also named the palliative, or Valsalva's treatment, from his being the inventor, in whose hands, as also those of others, it has succeeded. Cold astringent applications, especially ice, have been also recommended. But in aneurism of the extremities there are many cogent objections to this. In the first place, the patient may be so reduced by the confinement, as to be unable to withstand the subsequent confinement after the operation, since, in many cases, it is necessary to remain quiescent in bed for three or four months, for fear of secondary hemorrhage. In the next place, if much blood be effused, the absorbents are incapable of removing it, and inflammation, suppuration, and ulceration, or gangrene takes place, producing great reduction of strength. Thirdly, occasionally great pain is produced by the pressure. This plan therefore can only be judiciously pursued at the very commencement of external aneurism. The reader is referred to the essays and works of Senfio, Freer, Dubois, Sir William Blizard, Deschamps, Scarpa, Seiler, Percy, Duret, Assilini, and Crampton, for various modes of compression.

Formerly when this plan of Valsalva failed, amputation was performed, which however is now limited to those cases of diffused aneurism where it appears the absorbents cannot possibly remove the effused blood, and where extensive suppuration and ulceration of gangrene must be the result. About fifty or sixty years ago, the surgeons of Italy, emboldened by Haller's doctrine, drew a ligature around the popliteal artery both above and below the sac, which they laid open and removed the coagula. This extensive wound healed by granulations, or produced sinuses and caries of the bones, with contraction of the joint. Secondary hemorrhage from securing a diseased artery was also a frequent occurrence; and yet this practice is still followed by Boyer and many of the French surgeons. The celebrated John Hunter, perceiving such unhappy results, performed several experiments on the lower animals, and proved that an artery close to an aneurismal sac is so diseased that it must ulcerate; whereas, if secured between the tumour and the nearest large branch, so as to have the vessel healthy on the one side, and remote enough on the other from the branch, so that the latter would carry the blood along it on the principle of hydraulics, and leave the tied portion at rest, that a coagulum of blood might take place, and the adhesive inflammation not be disturbed, the operation would succeed in the majority of instances. He also saw, that if this operation was performed early enough, the flow of blood into the aneurismal sac would be so far checked as to allow further coagulation of it, and that ultimately both the blood and cyst would be absorbed. Accordingly, in 1785 he secured the superficial femoral artery for popliteal aneurism, shortly after its giving origin to the profunda, but he improperly employed four ligatures, whereas one is now found sufficient, for which important improvement we are indebted to Freer. This operation has undergone many important improvements by Birch, Foster, Freer, Abernethy, Dionis, Richter, Jones, A. Cooper, Travers, Hutchinson, Roberts, Lawrence, Hodgson, and Dalrymple.

The most improved method of securing the superficial femoral artery for popliteal aneurism, is that recommended by Walker, which appears preferable to that of Abernethy, Sir A. Cooper, Hodgson, C. Bell, Shaw, C. Hutchinson, Harrison, or Averil. To prove the necessity of measurement in this and all other operations for aneurism, the reader is referred to an unusual distribution of the superficial femoral artery operated on by C. Bell, and described in *Journal of Medical Science*, vol. iv.; also to Tiedemann, Barclay, Turner, Harrison, and Lizars's anatomical works.

The patient should be placed on a firm table, with the feet at right angles to each other, but the affected separated from the sound limb. The space between the anterior superior spinous process of the os ilium and the spine of the os pubis is to be divided into ten proportional parts, when five and a half measured from the pubes are made the base of an equilateral triangle, which is to be constructed downwards on the thigh, the apex being therefore distad, the base proximad; and the outer or iliac side of this triangle should be extended downwards from the apex twice its length, when the artery will be found to run beneath this line throughout. An incision should then commence at the apex of the triangle, and be continued down the thigh proportionally to the depth of skin and cellular substance of the patient, the latter of which is often infiltrated with serum; a second incision, equal in length to the first, should cut through the fascia lata, and this cautiously, when the pulsation of the artery will be felt; the artery is then to be denuded to the smallest possible extent of its cellular sheath, the latter of which is to be held up with the dissecting forceps in the left hand, and the scalpel in the right held parallel to the vessel, with its cutting edge pointing outwards or fibulad. The operator seeing satisfactorily the artery, vein, and nerve or nerves lying together, inserts the aneurismal needle, delineated in Fig. 5, Plate DXV. armed with a ligature, on the inner or tibial aspect, between the artery and the vein, and carries it round to the fibular aspect, as depicted in Fig. 2 of Plate DXVII. securing the artery with a single ligature of common unbleached linen thread, waxed and tied in the manner of the reef-knot of the sailor; and both ends of the ligature ought to be cut off close to the knot, and the lips of the wound approximated with adhesive plaster; the limb rolled with an eighteen-tailed flannel bandage (see Fig. 4, Plate DXVIII), from the toes to the groin, and applying an ordinary sized compress in the course of the artery from a little above its point of securement downwards, for five or six inches, and a larger one over the sac in the poples. The chief points to be attended to in operations for aneurism are, making clean free incisions, disturbing or insulating the artery as little as possible, and seeing distinctly the contiguous veins and nerves before throwing the ligature around; and if any nervous threads, as the nervus saphenus, so interfere as to impede the application of the ligature, they should be divided without hesitation. The surgeon judges of the artery being secured by the tumour becoming flaccid, and being divested of pulsation, with a diminution of the pain; and soon afterwards by a strong pulsation of the articular arteries. In the majority of cases, the temperature of the limb is rather higher after than before the operation. When an artery is thus secured, the ligature divides its muscular and serous tunics, the vessel shrinks, coagulable lymph is effused, and the adhesive inflammation excited, by which its sides and the wound throughout unite. Some days, or even weeks afterwards, we have known it six weeks, the noose or knot thus left behind, excites the most trifling degree of suppuration, the matter of which is chiefly absorbed, and advances slowly, and unfelt by the patient to the skin, like a plant growing to the light, and appearing like the smallest possible pimple, is ultimately discharged, the patient frequently not observing it.

Various kinds of ligatures have been invented and used, such as fine silk, inkle, dentist silk, twine, tailor's twist, catgut, and other animal matters, but one and all are ejected, consequently that which is smallest in diameter, and of sufficient strength is the best, and therefore we prefer unbleached linen thread, waxed. Mr. Fielding of Hull, has lately employed silk-worm-gut, and found it to be absorbed, but Dr. Crampton lost a patient in consequence of using it. If the operator should insulate the artery too great an extent, and thus cut off its connection with the contiguous structures, and destroy many of its *vasa vasorum*, he ought to throw two ligatures around it, at sufficient distance from each other, and divide the artery between them. If he wounds an arterial branch during the operation, it should be secured with a ligature as in ordinary operations. The wound is to be dressed on the third day, and every day afterwards until healed; the patient to remain quiescent in bed on low or farinaceous diet, until the wound is quite consolidated, avoiding every exertion, even in the change of his linens, which ought to be made to slip on and off so as to occasion the least possible disturbance, and using a urinal and bed-pan when required; three weeks at the very least should be allowed to transpire, before allowing him to sit up in bed, and to have more nourishing food, but even this only provided the wound be healed. The patients of Mott and Graefe, wherein the arteria innominata was secured, evidently fell victims to their being allowed to walk about too early. In such large arteries, and so near the source of the circulation, the patient should be kept in the horizontal attitude, on farinaceous diet, between three and four months.

Not unfrequently a slight pulsation returns in the tumour, which daily increases and constitutes a secondary aneurism, which may arise either from the inosculating branches between the ligature and the sac, or from others communicating directly with the sac, or thirdly, the blood may retrograde from the inferior or distal aperture of the artery into the sac. In such an event, we should first try the general or debilitating plan, and if it fails, secure the artery close above and below the tumour. and even if this last fail, perform amputation, but not amputate at once as recommended by some authors. There is another mode of operating for aneurism, invented either by Brasdor or Desault, and lately practised with success by Messrs. Wardrop, Lambert, Bush, and Evans, and advocated by Bichat, Scarpa, Hodgson, and Breschet. When the tumour is situated in an artery so near the source of the circulation, that a ligature cannot be thrown around the vessel between the heart and the sac; and this consists in securing the artery beyond or distad to the tumour. This method will evidently succeed, provided there is no arterial branch immediately contiguous to the sac, either on its proximal or distal extremity, and none originating from the tumour itself to induce the blood to enter the sac; for on applying the ligature, the blood will flow by the anastomosing branches proximad of the tumour, leave that in the sac quiescent, which will therefore coagulate and lay the foundation of a cure. This we consider an ingenious and very valuable operation.

Our limits will not permit us to enter into a detail of the various aneurisms which affect the different arteries with their operations; suffice it to say, that the arteria innominata, with its divisions, and the abdominal aorta, distad to the inferior mesenteric, with its divisions and subdivisions, have been secured. For an account of these aneurisms, the reader is referred to Hodgson on the *Diseases of the Arteries and Veins*, and for the steps requisite to be pursued in these operations, to Lizars's *Anatomical Plates*. The carotid artery was first secured by Mr. John Bell or Hebenstreit, a German surgeon; the subclavian by Mr. Ramsden: the brachial by Anel; the arteria innominata by Dr. Mott; the abdominal aorta by Sir A. Cooper; the internal iliac by Mr. Stevens; the gluteal by Mr. John Bell; the external iliac by Mr. Abernethy; and the common iliac by Dr. Mott.

Varicose aneurism, named also venous aneurism and aneurismal varix, occurs commonly at the bend of the arm from venesection, but has occurred to the subclavian artery and vein, the popliteal artery and vein, the common femoral artery and vein, and the posterior tibial artery and vein, from punctured wounds of these vessels. In this disease the artery and vein are simultaneously wounded, and a communication is established between them, by which the arterial blood flows directly into the cavity of the vein. When it takes place at the bend of the arm, inflammation is excited at the wounded points of the vein, the fascia of the biceps and the artery, forming a bond of adhesion between them, and a passage for the blood. A tumour is soon formed of a bluish colour, which pulsates like an artery, and communicates a tremulous motion to the touch, and rustling noise to the ear, somewhat resembling the hissing noise of air ejected from a syringe, and occasionally so loud during the night as to prevent the patient sleeping. The pulsation is only distinct in the centre of the tumour, and the contiguous veins are more or less varicose. The artery above, or proximad to the tumour, becomes larger, and vibrates strongly, while below, it is smaller. If the tumour be emptied, and sufficient pressure be applied, either above or below, to check the cutaneous venous circulation, it immediately fills; but if the pressure above be enough to compress the brachial artery, the tumour diminishes. This species of aneurism appears sometimes within three or four hours after venesection, while at others not for several weeks; it has a circumscribed appearance, is about the size of a large walnut, with the cicatrix made by the lancet in the centre. It increases very slowly, excites little pain, producing more a sense of weight, numbness and feebleness of the arm, and is the least dangerous of aneurisms, never rupturing spontaneously, but being liable to be converted into the false, with which it is sometimes complicated. The treatment consists in the application of compression and bandage, wearing the arm in a sling, or keeping it in the horizontal position; or, lastly, in securing the artery, which probably from its being the shorter means of cure, and perfectly safe, is the best remedy.

Aneurism by anastomosis, named also nævus maternus, tumeurs variqueses, or fongueses sanguines, tumeurs erectiles, hæmatoncus, blood-sponge, and in common language, strawberry or raspberry tumour, begins usually at birth, having the appearance of a red, purple, or livid stain, but occasionally there is at once a distinct prominent vascular tumour; in some cases the disease remains long dormant, while in others, this vascular plexus of vessels increases in number and size distending the skin, which ruptures in sultry weather, or in intense cold, producing hemorrhage, which becomes each time more momentous, until at last it proves fatal. This is particularly the case when it attacks a surface delicately covered with integuments, as the lips. It is more frequently situated about the head than elsewhere, sometimes involving a great extent of surface, lips, mouth, fauces, pharynx, neck, and chest; and the same vascular plexus has been discovered within as well as without the cranium, the capillaries of the dura mater being equally affected. This disease has occurred occasionally in the adult, from accidental violence, beginning in the form of a mere pimple or speck, and soon becoming a throbbing incontrollable vascular tumour, bleeding on the slightest exertion, drinking, mental emotion, exposure to the sun or cold. In infancy this disease must be distinguished from the congenitæ notæ, or growths of hair, &c. John Bell, who first correctly described this vascular tumour, conceived there were cells intermediate to the capillary arteries and veins, in which opinion he is joined by Dupuytren and Wardrop, but from what we have witnessed in careful injection and dissection of such tumours, and what is developed in the spleen, placenta, corpus cavernosum et spongiosum penis, especially the latter in the elephant, no cells exist in these tumours, but that the delicate veins form large and frequent anastomoses, which, from communicating freely with each other, and adhering together, resemble cellular tissue.

In young children, before they have been inoculated, it has been cured by inducing adhesive inflammation with vaccine lymph, and obliterating the blood-vessels; but this fails in the adult. If this application fails, or the child has been already vaccinated, in which case it seldom succeeds, compression should be tried, together with astringents, and if both of these fail by the time the child is four months old, it should be treated by ligature, as recommended by John Bell, White and Lawrence. The securing the arteries leading to the tumour has been occasionally successful, but has as often failed, even in the most scientific hands. The extirpation of the tumour is objectionable in early life, as we require to cut at some distance from the tumour, in order to avoid the blood-vessels, thus leaving a great extent of surface to granulate and cicatrize, and causing considerable deformity, if situated about the head and neck. Potassa, or kali purum, applied so as to produce gentle ulceration and sloughing, has also succeeded, but it is only advisable in very small nævi materni, as it has proved fatal even in Boyer's hands. For an elaborate detail of the diseases of the arteries, the reader is referred to Hodgson *on Dis. of Art. and Veins*—Breschet's *Translation of same. Ed. Med. and Surg. Journal*, vol. xxii. p. 4, and vol. xix. p. 45, and *Ed. Med. Chir. Trans.* vol. iii., also to mortification, already mentioned in this article

Under bloodletting we have shown the proneness of the veins to inflammation, and its fatal tendency; and also under ulcers with varicose veins, adverted to the impropriety of securing them with a ligature. The uterine, the crural, the external, the internal, the common iliac, and spermatic veins, even onwards to the renal and vena cava inferior veins, have been found inflamed, thickened, and filled with purulent matter and coagulated lymph, after abortion, ordinary accouchment, and in puerperal fever. Similar appearances have been seen in phthysis pulmonalis and in carcinomatous affections of several organs. A greyish coloured fluid has been found in the splenic and hepatic veins. Inflammation in veins, although rarely, sometimes terminates in ulceration, producing hemorrhage, and commonly begins in the serous tunic; the adhesive inflammation, however, more frequently obliterates their cavities and prevents hemorrhage: and when sphacelation occurs in the contiguity of veins, they become plugged with coagula of blood, as already mentioned under mortification. In violent exertions, cramps, cold stage of ague, and blows, the veins are sometimes lacerated. The veins, from gravity or pressure, frequently become varicose, or present a serpentine swollen knotted appearance, on the lower extremities, the spermatic cords and scrotum, the spermatic plexus of the ovaria, the rectum, especially at its termination or around the anus, and on the integuments in the hypogastric and inguinal regions. In many of these, especially the cutaneous of the leg and the hemorrhoidal veins, coagula of blood are found, which, obliterating the cavity, have produced a spontaneous cure. The veins are also subject to circumscribed distension or dilatation, varying in size from a small nut to that of a pigeon's egg, and sometimes to such an extent as to rupture and prove serious and even fatal. These distensions are occasionally accompanied with pain, and, when situated superficially, sometimes with inflammation and suppuration of the skin and cellular substance in their vicinity, forming ulcers.

The treatment of varicose veins consists in affording them support, or obliterating them with potassa. The saphena major and minor of the leg, when affected, require the roller to extend from the toes to the groins, and are much benefitted by being bathed with a decoction of oak bark, and attention paid to the bowels. When potassa is used, it is applied above or proximad to the varicose portion of the vein, so as to produce an eschar on the skin, by which the vein inflames, the blood coagulates, effusion of lymph follows with an adhesion of the sides of the vein and consequent obliteration of its canal. The veins, like the arteries, have been found cartilaginous and studded with calcareous depositions, and loose calculi in their cavities. In some cases the same diseased structure as that in the vicinity, as, for example, schirrus, has been found growing from the serous tunic of veins. The largest veins of the system, even the vena cava inferior, have been found obliterated, and the circulation carried on by the superficial ones, and the vena azygos.

Hemorrhage from αιμα *blood*, and ῥηγνυμι *to break out*, the dread of both the ancients and moderns, has greatly retarded operative surgery, and precisely in proportion to our ignorance of anatomy. When an artery is wounded, the blood of a bright vermilion colour flows in distinct jets, while when a vein is cut, it flows of a dark purple colour, in a more equable or smooth stream. In the smaller veins contiguous to the capillary arteries, the stream is interrupted, or flows *per saltum*, as if an artery was wounded. When an artery is merely punctured, the hemorrhage generally soon produces fainting, and the blood injects its cellular sheath, which forms a coagulum that becomes a temporary barrier to its flow; but if this process be disturbed, or if inflammation and ulceration follow, the hemorrhage recurs from time to time, until at last it proves fatal. In such cases, therefore, if the vessel be large, as that of the thigh, it should be instantly secured by throwing a ligature around, above and below the seat of the wound, as the retrograde flow from the free inoculation is liable to reproduce the bleeding. But if no disturbance accrue to this process of nature, the wounded edges of the artery inflame, effuse coagulable lymph, and are united by the adhesive inflammation; and if the wound be trifling, the continuity of the vessel is preserved. A long continuance of quiescence is requisite, however, to ensure safety from aneurism. It will be at once seen, that the same causes preventing the success of securing the principal artery of a limb for aneurism, will operate here, and that mortification will be even more liable to follow in this case. When an artery is divided transversely, an impetuous flow of blood takes place, producing fainting, its ends are constricted and retract into the contiguous cellular tissue, which is injected with blood, that soon coagulates, while the blood flows by the proximal branches, allowing a coagulum of blood to take place in the trunk, which thus gradually becomes obliterated, as if secured in aneurism, and thus the hemorrhage is for a time arrested. If this natural process be undisturbed, slight inflammation follows with the effusion of coagulable lymph in the artery, between its coats, and in the cellular substance in the vicinity, which becomes gradually consolidated, and proves a perfect barrier to after bleeding. This, however, is not always the case, particularly if a branch be near the wound, the blood flows impetuously by the trunk, produces fainting, which recurs at each successive rallying of the system, or at once proves fatal. The artery consequently ought to be secured, as in the first instance. If the axillary in its mesh of nerves, veins, and branches, be wounded with a sharp pointed instrument, the subclavian as it runs over the first rib should be tied, and compression applied to the wound, as was lately practised by Langenbeck with success.

Hemorrhage from an artery has been divided into primary and secondary; the former when it occurs within thirty hours after the receipt of the wound, or rather when reaction of the system has taken place; secondary, when it takes place after this period, for the time is so very uncertain, that no definite time can be specified. When the smaller arteries are wounded, as those in the palm of the hand or the sole of the foot, compression with dry sponge, sponge tent, agaric or lint, and a bandage should be employed; and if this fails, the trunk of the bleeding artery secured proximad to the hand or foot, continuing however the pressure. Sponge tent consists of sponge dipped in melted wax, and forcibly pressed into the smallest possible size. The same kind of compression is applied to the internal pudic artery when wounded in lithotomy, to the intercostal arteries, the temporal, and the extreme branches of the internal maxillary after the extraction of a tooth. When a vascular surface, as the mucous membrane of the nares is bleeding, escharotics, styptics, and compression by dry lint are used. If the bleeding proceeds from the stomach, styptics are administered, and venesection to produce fainting, which highly favours the natural process of arresting hemorrhagy; with these are combined cathartic enemata, low diet, and perfect rest. If from the lungs, the same remedies, combined with narcotics and gentle laxatives. When from the corpus spongiosum or cavernosum penis, compression and bandage. The styptics in use are cold water, vinegar and cold water, solutions of the sulphates of zinc, alum, iron, or copper, of the nitrates of silver or copper, the mineral acids, diluted alcohol, alcohol, and sulphuric acid combined. If the bleeding is from the gums, or antrum maxillare, or orbit, after a surgical operation, compression or the actual cautery is requisite.

Fracture, from *frango, to break*, is applied to the bones, and is divided into simple and compound; simple, when the bone only is injured; compound, when the soft coverings are so injured that either one of the fractured ends protrudes through the skin, or the skin and muscles are so lacerated as to expose the bone, the long cylindrical bones of the limbs are most frequently fractured; next the flat, particularly of the cranium, for those of the pelvis and scapula must be excluded; and lastly, the round irregularly shaped bones of the tarsus, carpus, and vertebræ. The bones are fractured by external violence, disease, and the action of the muscles. The long cylindrical bones are not unfrequently broken in more than one point; they are generally fractured at the centre of their shafts, in which case the fracture is more or less oblique; whereas, when it occurs near the extremes, it becomes more and more transverse; hence, fractures have been divided into oblique and transverse. The spongy bones are also fractured transversely. The flat bones in various directions, occasionally stellated. A comminuted fracture occurs when a bone is broken in different places at once, and divided into several fragments or splinters. Longitudinal fractures also occur to the long cylindrical bones. Complicated fractures are those accompanied with luxation, severe contusions, wounded blood-vessels, pregnancy, gout, scurvy, rickets, fragilitas, ossium, and syphilis, which diseases prevent the union of the bones, and also cause them to be very easily broken. Cold renders the bones more fragile, and they are also more brittle in old age. The superficial are more exposed to fracture than the deep seated bones; thus the clavicle is more so than the os innominatum. Others, from their functions, are more exposed; as, for example, the radius from its affording support to the carpus.

When a fracture takes place, there is an effusion of blood from the vessels of the bone, periosteum, and contiguous soft parts, the muscles are violently excited, the periosteum and truncated ends of the bone inflame; and after the inflammation subsides, the vessels of the periosteum and ends of the bone are formed to secrete callus, which is an effusion of gelatin that is gradually converted into cartilage, and lastly into bone by the secretion of phosphate of lime, precisely in the same manner as the formation and conversion of bone in the fetus. During the inflammatory action, no diseased secretion whatever takes place; nay, even the healthy natural ones are more or less suspended, so that no advantage is gained by setting a fracture immediately after the injury; on the contrary, this primary setting, as it is termed, re-excites the already spasmodic action of the muscles, and in nine cases out of ten disappoints the hopes of the surgeon. Callus does not harden for many days; in the adult, it begins generally about the tenth or twelfth day; Boyer, however, says that it is not formed until between the twentieth and seventieth day. The treatment of a simple fractured bone is to lay the limb in the easiest position for the patient, which is probably in M'Intyre's fracture splint, delineated in Fig. 6, of Plate DXV. to apply leeches and anodyne fomentations or poultices, to put him on low diet, enjoin perfect rest, and administer gentle laxatives, until all inflammatory action is subdued; then to extend the limb to its natural length, or apply pasteboard splints dipt in warm water, with wooden ones exterior to them, and fastened with tapes. This latter is termed secondary setting, and is applicable to all the bones of the extremities, and is best exemplified in the os femoris.

The thigh bone is fractured at every point, but more frequently in its centre, in which case the fracture is oblique and splintery, accompanied with crepitus and great retraction of the muscles, rendering the limb shorter and thicker, and the distal portion extremely moveable and overlapping the proximal, while the patient is unable to move the limb. If much spasmodic action of the muscles has taken place, no power we possess can lengthen and retain the limb in its situation. The limb should be retained in the fracture-splint, for fully three weeks after inflammation has been subdued, but may be examined every third or fourth day. More or less œdema supervenes, which is easily discussed by friction and bandage. This mode of treatment is applicable to the tibia, fibula, os brachii, ulna, and radius, when affected with simple fracture.

When there is a compound fracture of the os femoris, and if the bone protrudes such a length that it cannot be with facility reduced within the skin and muscles, it should be sawn off, for it would produce too much injury of the soft parts, to make an incision calculated to replace the protruded portion; but in the tibia, and other thinly covered bones, the integuments may be incised to permit the bone to be replaced. After the os femoris has been replaced, the wound, if simple, ought to be approximated with adhesive plaster, but if contuse, leeches and poultices, or fomentations are requisite. No callus is secreted during suppuration; and as this wound will suppurate, the limb should be placed in an easy attitude on M'Intyre's fracture-splint, an eighteen-tailed bandage applied to prevent the pus burrowing, and to keep on the dressings, which should be simple; and as suppuration ceases callus is secreted, and then the attitude of the limb must be attended to. When suppuration is established, the diet should be nutritious. If the fracture be comminuted, we extract the loose fragments of bone, and treat it afterwards in the same way as has been described; but from the depth of muscular substance, which prevents extraction of these fragments, and the escape of pus when formed, amputation often becomes a matter of consideration for the surgeon; or if in this fracture the femoral artery is wounded, or the knee joint involved, amputation should be performed. This mode of treating compound and comminuted fractures of the os femoris is also applicable to those of the tibia, fibula, os brachii, ulna and radius.

In fractures of the bones of the upper extremity, we have to consider that the arm has no weight to support, is nearer the source of the circulation, and its arteries inosculate more freely with each other, and its returning or venous circulation is more easily performed, consequently in compound fractures, an attempt to preserve the limb may be made with more propriety.

The os brachii when fractured is probably more disposed to form a false joint than any other bone, although in several cases the thigh bone has been affected with this disposition. In this process each fractured extremity secretes callus, which becomes cartilaginous, but never ossifies; and around these ends a synovial pouch is formed by the cellular or muscular tissue, which secretes synovia, and thus forms a rude joint, but so moveable as to render the arm useless. This flexible condition is to be treated with a simple apparatus of leather and iron, to prevent this false joint from moving; and if this fails, the ends of the bone may be rubbed on each other with the view of inflaming and exciting them to more action, the limb afterwards being firmly bound up for a time, or an incision may be made down to the disunited ends of the bone, and rasped or sawn off, and then the bleeding ends put in apposition, and treated as if recently fractured. A third method is the employment of a seton, all of which have occasionally succeeded, and as often failed.

The ribs are generally fractured near their centres, and commonly more than one at a time, and the middle ones more frequently than the extremes; from the lungs being close to them, and their fracture oblique and splintery, such accidents are extremely dangerous. When a simple fracture occurs, it is treated as directed in luxation of their sternal ends, together with local and general blood-letting. If the pleura costalis be injured in this accident, inflammation and suppuration of this membrane may follow, and lay the foundation for empyema (from εν *within*, and πυον *pus*), or a collection of matter in the pleuritic bag; but empyema may be produced by various other causes besides a fractured rib. The greatest difficulty in this, and in all diseases, is a correct diagnosis, which if clear in this case, the matter must be evacuated by an operation termed paracentesis thoracis (from παρακεντεω *to perforate*), which consists in holding up the integuments over the sixth and seventh ribs in their centres, in order that they may act afterwards as a valve, and making an incision through them to the extent of two or three inches, parallel and close to the upper edge of the seventh rib, then dividing to a more limited extent the serratus magnus and intercostal muscles carefully until the pleura costalis appears, which should be punctured with a lancet, and a canula afterwards inserted to remove the matter. When all the fluid has been removed, the wound should be closed and treated on the principle of chronic abscess, which it more frequently resembles, than the acute. This operation is also performed for collections of serum or water, for extravasated blood, and for diffusion of air in the pleuritic bag. A fractured rib occasionally wounds one of the intercostal arteries, which pours out its blood into the pleuritic bag, oppresses the lungs, and afterwards produces empyema; and various instruments have been contrived to suppress this hemorrhage, but the finger of an assistant is undoubtedly to be preferred, and if there was only one rib injured and hemorrhage continuing, the surgeon would be justified in making an incision and thus compressing the artery, or first dividing it so as to allow its ends to retract, and then applying compression; on the contrary, however, in consequence of there being more than one rib fractured, he is only authorized in using the lancet freely and administering digitalis and hyosciamus. One of these arteries may be wounded by a small sword or bayonet, in which case the above treatment by compression is to be adopted. The lungs themselves are sometimes wounded by a fractured rib, producing either hemorrhage or emphysema (from φυσαω *to inflate*.) When hemorrhage is the result, it is commonly alarming and requires active antiphlogistic treatment.

Emphysema consists in the air of the lungs issuing into the bag of the pleura, and generally from thence into the cellular tissue in the vicinity of the fracture, and ultimately over the whole integuments of the thorax, and even the whole body. If the air which is inspired by the lungs, and from them issues into the pleuritic bag, does not escape at the wound of the pleura into the subcutaneous cellular tissue, it makes the lungs of the affected side collapse, and by accumulating in the one bag of the pleura, presses on the mediastinum and diaphragm; and this so impairs the functions of the other half of the lungs and the smaller circulation, as soon to prove fatal. The escape of the air, therefore, from the pleuritic pouch into the cutaneous cellular tissue is favourable. Blood is often extravasated, as well as air, in the pleuritic bag, and the lungs become inflamed. The treatment consists in making punctures with a lancet in the region of the fracture, or wherever the air is diffused, and if oppression of breathing continues, paracentesis thoracis should be performed, and a cupping glass with its syringe applied to the wound. Emphysema results also from the wound of a sword, or any other sharp pointed instrument, from the bursting of a vomica, from violent respiration during parturition, from foreign bodies in the larynx and trachea, from blows on these organs, and even on the back of the neck; from violence in the reduction of a dislocated shoulder joint: from a suppurated lymphatic gland in the region of the neck, and as a sequela of pneumonia and typhus fever. The ribs sometimes become carious after fracture, and require to be removed.

Luxation or *Dislocation* (from *luxo* or *disloc*, *to put out of place*,) is the displacement of those bones which form a joint, and may occur either spontaneously or in consequence of external violence. When dislocation occurs spontaneously, it arises from relaxation of the ligaments and muscles; from palsy; from matter accumulated in the joints affected with white swelling or morbus coxarius. The other species of luxation, and much the more common, results either from violent motions or external injury, and is divided into simple, compound, primary, consecutive, complete, incomplete, and subluxation.

The shoulder joint is dislocated in four directions; the head of the os brachii may be forced either directly downwards into the axilla, inwards on the venter of the scapula, backwards on the dorsum of the scapula, or upwards on the coracoid process of the bone. The first of these is much the most frequent, and is probably the most common luxation that occurs; it is characterized by a conspicuous depression beneath the acromion, in place of the round swell of the shoulder, by the patient inclining his body to the arm, in order to relax the muscles, nerves, and blood-vessels, and relieve the pain, by his supporting the arm with his other hand or on his knee, and not being able to bring it close to his side, or lift it to his head. The capsular ligament and short muscles around the joint are more or less lacerated, while the pectoralis major, the deltoid, latissimus dorsi, teres major, and biceps are thrown into violent action, and contribute to produce the displacement by their sudden contractile efforts, which are performed to prevent the displacement of the bones. The head of the os brachii is forced out of the glenoid cavity between the long head of the triceps and the subscapularis, and rests on the inferior costa of the scapula. This is an example of simple, primary, as well as complete luxation. The arm is a little longer, but the difference is scarcely perceptible; the head of the os brachii is sometimes felt in the axilla, when the arm is removed from the side; paralysis occasionally occurs from pressure on the nerves, and crepitus from gurgling of the synovial fluid, which latter phenomenon is exceedingly liable to deceive the surgeon. Various modes of reduction have been recommended both by the ancients and the moderns; but the most simple and sure method is to fix the patient firmly and properly, as represented in Fig. 10, of Plate DXVII. so that the scapula is made the resisting point, which may be accomplished with a sheet or an apparatus having a hole to admit the arm to pass through, to which is to be affixed a rope extending to a beam of wood or kitchen poker laid across the outside of the door or window of the room, a wet towel is then to be applied to the affected arm above the elbow-joint, and over this, a hank of worsted in the form of the double clove-hitch, to the nooses of which the one end of the pulley apparatus is to be affixed, while the other end is fastened to a piece of wood placed across a door or window opposite the other. When every thing is thus properly adjusted, the patient is to be bled to fainting, and supported in a chair by an assistant, while another instantly begins extension, and continues it gradually and slowly until the surgeon, by poising the head of the os brachii with a towel folded like a bandage or compress, raises it opposite the glenoid cavity of the scapula into which it starts with a peculiar sound; the assistant then suddenly loosens the pulley apparatus and removes it. The operator next puts a cushion in the axilla, bends the forearm across the chest, binds it there to the side, and gives support to the elbow with a long roller, as illustrated in Fig. 9 of Plate DXVII. In general, tartrate of antimony in small doses should be given before using the lancet, as a great quantity of blood is often required to be taken in order to produce fainting.

More or less inflammation occasionally supervenes to luxation, and its necessary reduction, and may require local and general blood-letting, fomentations, local irritants, low diet, cathartics and confinement to bed. The arm should be kept quiet for at least three weeks, to permit the lacerated capsular ligament and muscles to heal, and afterwards passive motion allowed; but the patient ought to be cautioned against lifting his arm with too much freedom, as this luxation is extremely liable to be reproduced. Emphysema, ecchymosis, rupture of the axillary artery, and large abscesses have occurred from reduction. Reduction of this luxation may be attempted during any period within three months; but some have succeeded at the distance of ten months; much, however, must depend on the constitution and violence of the injury, for inflammation, mortification and death have followed attempts at reduction beyond three months. In old luxations, a warm bath should be used immediately before reduction is attempted.

If the head of the os brachii is not reduced, but pulled up by the muscles towards the clavicle, it is then termed a consecutive luxation, a form of the disease said by Sir A. Cooper to be primary. Larrey relates a luxation, where the head of the os brachii was wedged between the second and third ribs. The head of the os brachii now forms a new joint, the inflammation induced consolidates the muscles and cellular substance, which form a cartilaginous bed and a rude capsule, the loose muscles around contract and become rigid, and accommodate themselves to their new functions; the old capsular ligament heals up and the glenoid cavity is filled up with a soft gelatinous adhesive substance. Compound luxation of this joint seldom or never occurs; dislocation, however, with fracture of the neck of the os brachii, fracture of the acromion scapulæ, or fracture of the cervix scapulæ sometimes takes place; and each of these fractures occasionally present themselves without the luxation, so that we ought to be careful in distinguishing between them.

Compound luxation occurs probably more frequently at the ankle joint than at any of the others:

this consists in a protrusion of either the tibia singly, or tibia and fibula combined, through the skin, and the foot hangs loosely on either side of the leg. Compound luxation also comprehends the injury of the integuments and soft coverings, and the exposing of the bones of the joint to the external air. In such cases, if the bone cannot be reduced within the soft parts, it ought to be sawn off; or the practitioner must take into consideration amputation of the limb; for our own parts, we are disposed to prefer amputation, to the tedium of suppuration, exfoliation, and partial anchylosis, at the imminent hazard of the patient's life, consequent on the violent constitutional and hectic fever, gangrene, or tetanus during the cure. If an attempt be made to save the limb, the wounded arteries are to be secured, as many pieces of bone should be gently removed as can be done with facility and promptitude, the protruded bone washed, and either reduced or sawn off, the wound approximated by adhesive straps and suture, and covered with dry lint, and laid on a soft pillow or placed in M'Intyre's fracture-splint. Considerable inflammation, together with suppuration, generally follows, and requires most active antiphlogistic treatment. Simple luxation of the ankle joint may be mistaken for fracture of the tibia into the joint, and for a sprain of the tendons in this region.

Sprains consist in the laceration of the vaginal ligaments or sheaths of the tendons of muscles producing an effusion of lymph in the contiguous cellular tissue, and occur most frequently on the back of the hand; they also affect the muscles themselves by overstretching and slightly lacerating their fibres. In sprains, there is almost immediate discolouration, but no tumefaction until some time after the accident, which is generally only on one side of the joint, but occasionally on both. Sprains are treated first with leeches and warm anodyne applications, and secondly with stimulating liniments, friction and bandage. Ganglions or ganglia are either the result of sprains or bruises, and consist of an effusion of lymph, or the mucous secretion of the sheaths of the tendons; they appear in the form of a circumscribed, moveable, elastic tumour, free of pain, but frequently incommoding the individual in the motions of the parts, particularly if situated on the foot. They should be treated with pressure and bandage, and if these fail, with extirpation of the entire cyst. Sir A. Cooper recommends striking them a smart blow with a book, in order to rupture the cyst, and diffuse the glairy fluid into the cellular tissue that it may be absorbed.

Besides luxation, the joints are subject to many diseases, to inflammation, synovial and serous effusion, suppuration, ulceration, anchylosis, and loose cartilages floating in them. Inflammation has been already noticed under luxation, and which may be produced by the same causes as those that excite it on ordinary occasions, and the treatment requires to be extremely active, both locally and constitutionally, according to the magnitude of the joint and the severity of the injury. When the knee joint is very slightly inflamed from an exposure to cold, the synovial membrane secretes more synovial fluid than in health; and if the inflammation be a little more severe, this fluid becomes more watery, occasionally pure serum or dropsy, which constitutes *hydrops articuli.* From this view, it will be seen, that dropsy is an overabundant effusion of the serous portion of the blood, dependent either upon increased secretion of the exhalants, or on diminished absorption, or on a combination of both. This termination is still better illustrated in the serous cavities of the brain, thorax, or abdomen. If all inflammatory action has abated, the effused fluid into a joint may be discussed with a succession of blisters, compress and bandage, and if these fail, it should be evacuated by a valvular opening made with a bistoury on the outside of the joint between the patella and external condyle of the os femoris. This dropsical effusion is occasionally confined to the bursa under the patellar ligament, and then presents a globular swelling; but when it attacks the bursa under the cruræus muscle it invariably communicates with the joint.

When inflammation is more severe than to terminate in synovial or serous effusion, it ends in the secretion of coagulable lymph, that produces more or less perfect anchylosis; which is the union of the cartilaginous surfaces entering into the formation of a joint, or the osseous texture itself, rendering the articulation stiff and immoveable. In such cases, the treatment requires to be still more active; four or five dozen of leeches should be applied, followed by anodyne fomentations, alternate blisters and moxas, perfect rest, with the limb placed in M'Intyre's fracture-splint, gentle laxatives and low diet; and the puncturing of the joint to give exit to any effused lymph if necessary. The leeches may require to be repeated. A patient should be kept confined to bed until every vestige of inflammation has either been subdued, or the joint quite locked by anchylosis, when a splint of some apparatus ought to be worn to prevent the joint shaking; and even then the slightest motion of it ought to be carefully avoided.

When the inflammation is so severe as to terminate in suppuration, with thickening of the cartilages and ligaments; an effusion of viscid lymph into the cellular substance around the joint, rendering it thick and soft; a peculiar alteration of the adipose and tendinous substances constituting the chief part of the swelling; and the skin assuming a pale tense glistening colour with large veins;—the disease has been termed white swelling. The purulent matter is commonly of a shining coagulated nature. This disease, which occurs chiefly in early life, is almost exclusively confined to the scrofulous diathesis, which in so moist a climate pervades almost every constitution. The inflammation is sometimes slight, and recurs for several successive periods before advancing to suppuration, and occasionally appears alternately acute and chronic. The matter either remains within the articulation, or ulceration of the capsular ligament ensues, when it burrows in various directions, occasionally advancing to the skin in long fistulous tubes. Ulceration of the cartilages and caries of the bones, accompanied with hectic fever, takes place, and carries off the patient. The treatment is the same as that recommended in the last, only it ought to be more rigidly enforced. A peculiar treatment has been lately recommended by Mr. Scott of Bromley, which can only be applied to the early and mild stages of this disease; and a similar treatment is extolled by Richerand. When ulceration of the cartilages and bones have taken place, amputation is too often the only remedy. The rheumatic species of white swelling appears to be nothing more than the inflamed rheumatic joint terminating in suppuration. White swelling attacks the elbow, wrist, and ankle joints, as well as the knee, but the last most frequently.

In wounds of the joints, particularly so large a one as the knee, violent inflammatory action should be apprehended and treated accordingly. No probing whatever should be employed, synovia being easily distinguished from pus. The stomach is peculiarly affected by wounds of this joint, and a blow on the knee produces fainting and vomiting, and also affects the brain.

The articular surfaces forming the joints, especially those of the elbow and the knee, have been excised in an ulcerated state; the operation of the latter consists in making a crucial incision of the integuments on the patellar aspect, so that the transverse one may extend between the os femoris and the tibia; and dissecting aside each angle of the flap extensively from the patella and capsular ligament. The patella is then removed, the lateral and crucial ligaments divided, by which the condyles of the os femoris can be made to project on bending the leg on the thigh, and then can be carefully and slightly cleaned and sawn off from above downwards, a piece of firm leather being interposed between the bone and the popliteal vessels. The head of the tibia is next to be divested of its soft coverings, and projected so as to be sawn off from within outwards. One or more of the articular arteries may require to be secured, the flaps approximated, and then the cut ends of the tibia and os femoris are to be retained in apposition by an ingenious apparatus. There are many cogent objections to excision of the joints, few recovering the least use of them.

The disease which attacks the hip-joint, and which is termed the hip-joint disease, morbus coxarius, scrofulous-hip, or scrofulous caries of hip, is evidently a species of white-swelling, consisting first of inflammation, and suppuration of the synovial membrane and ligaments, and afterwards of ulceration of these and the cartilages and bones. This joint has been affected with fungus hæmatodes, deceiving the surgeon for morbus coxarius. When anchylosis has supervened after this affection, a joint may be formed at the cervix of the thigh bone, which consists in making the crucial incision over the trochanter major, and sawing the cervix close to this process of the thigh bone, and preventing union by ossific matter during the cure. In old age, the interstitial absorption of the cervix of the os femoris takes place, which alters the angle formed by it and the shaft, and so shortens the limb that it may be mistaken either for luxation or fracture. An affection, precisely resembling morbus coxarius, sometimes affects the sacroiliac synchondrosis.

Loose cartilaginous bodies are found in the joints, particularly the knee, and if they cannot be confined with a laced knee cap, so as not to impede the motions of the joint, they should be extirpated. The patient ought to be previously confined to bed for a day or two, and have a cathartic administered; the cartilaginous substance should then be pressed towards one side of the patella, and there held firmly by an assistant, while the operator drawing the skin downwards, or upwards, or to one side, makes a longitudinal incision over the substance, and extracts it either with the fingers, forceps, or a hook. The skin is instantly to be allowed to retract, the lips of the wound approximated with adhesive plaster, and the eighteen-tailed bandage applied, the limb gently extended, and perfect rest, with low diet, enjoined. Inflammation is to be apprehended after this operation, and treated accordingly.

The bones are subject to the same diseases as the soft parts of the body, the phenomena merely differing in consequence of the hardness of their structure; thus they are attacked with inflammation, suppuration, abscess, ulceration, mortification and carcinoma. Inflammation is termed ostitis, and is characterized by the same symptoms and appearances, as described under inflammation, the pain being more or less severe, according to the hardness or compactness of the bone, which, in consequence of its unyielding nature; prevents the expansion of the nerves and blood-vessels; the redness, tumefaction, and increased heat being more or less developed, according to the exposed nature of the bone. The same mode of treatment is also to be followed, with this difference, that as the bones are deeply seated, incisions, the moxa, and other counter irritants are more necessary. The soft spongy bones of the carpus and tarsus, the epiphyses of the long ones, and vertebræ when inflamed, are, in consequence of the blood-vessels having sufficient latitude, capable of forming suppurative papillæ, and thus abscesses are formed, which are treated in the same way as formerly directed. Abscesses in the bones frequently accompany necrosis.

These bones, upon the same principle when inflamed become carious, or, in other words, the abscess bursts, or the supurative papillæ are exposed, and the bone is found ulcerated for caries, (from κειρω *to abrade*,) is considered by modern surgeons, ulceration of the bones, and, consequently, is subject to the same varieties as ulcers of the soft parts; and caries not unfrequently follows ulceration of the contiguous soft parts. When caries attacks one of the carpal bones, a deposition of callus is occasionally generated, which forms a barrier to the progress of the disease; at other times a carious bone becomes soft and diseased throughout, having a fleshy or fatty appearance; on other occasions it becomes dry and friable, crumbling down under the probe; in some instances a separation takes place between the carious and healthy portions, the former being thrown off like a slough. Caries generally attacks the surface of a bone, and extends deeper and deeper, but occasionally it begins in the centre; when the bones of the carpus, tarsus, or vertebræ are attacked, it very frequently spreads from one to another; the cartilaginous surfaces of these bones resist the disease longer than the osseous shells. When this disease attacks the sternum, or any other superficially seated bone, the malady is more easily cured, than when a deep seated one, such as the acetabulum of the os innominatum. Caries attacks the young constitution much oftener than the adult, and spreads with greater rapidity, but heals more quickly, and occurs chiefly in the scrofulous and syphilitic constitutions. From the preceding facts and observations, it appears that caries may be divided into as many species or varieties as ulcers; therefore there are, the simple, the inflamed, the indolent, the phagedenic, the gangrenous, the scrofulous, the syphilitic, and the scorbutic caries; and consequently on this account the carious ulcer, described by authors, evidently involves two or three species of caries or carious ulcers. Some authors make other divisions of this disease, which are equally objectionable. The simple caries is clearly seen in the end of a bone which protrudes after amputation, in compound fracture when the bone is freely exposed, and in caries which commonly attacks the sternum. In these there is no difference from that which occurs in the simple ulcer of the soft parts, and none in the treatment. If the carious portion is not freely exposed, the integuments and all sinuses of the bone should be freely laid open, there being as much or more necessity for bringing it into view than even the ulceration of the soft parts. The irritable or inflamed caries presents the same granulations and discharge as the inflamed ulcer does; it is this species only which tinges the silver probe yellow or black, and when it attacks one of the bones of the carpus, or tarsus, spreads and involves so many, that not unfrequently amputation of the hand or foot is necessary. The antiphlogistic treatment requires to be vigorous in such cases, and all abscesses or sinuses must be freely laid open. If the caries becomes phagedenic, the portion must be removed with the trephine or knife, or destroyed with the actual cautery, nitrates of silver or copper, and if these fail, amputation ought to be performed. The cautery requires to be applied with great caution. But if the caries assumes a simple or healthy aspect, it is to be treated accordingly; or if it becomes indolent, to be stimulated with solutions of the nitrates of silver and copper, sulphate of copper, muriate of mercury, and oxide of arsenic. Moxas applied in the neighbourhood of caries are powerful auxiliaries; thus when the astragalus, tibia and fibula have been carious, moxas around the ankle joint have cured them. The phagedenic caries is best exemplified in severe cases of noli me tangere. The fungous caries is best illustrated in caries of the sternum, where the granulations are occasionally very large and flabby. The scrofulous caries, or caries occurring in the scrofulous constitution, affects either the vertebræ or the joints, the latter of which have already been considered; and when the former are the seat of this disease, either distortion with or without paralysis of the lower extremities, or lumbar abscess, is the result. From the great weight which the spinal column has to support, and the delicate spongy nature of its structure, it is very readily distorted even from continued awkward or awry attitude in the young and delicate scrofulous female. Whenever the muscles on the one side of the spine gain the least ascendency over their antagonists, they instantly lay the foundation for distortion, and in many cases, sooner or later, caries is the consequence. If early attended to, the common steel stays, as represented in Fig. 22, Plate DXVI. should be worn when the patient is erect, but the greater portion of the twenty-four hours should be passed in the recumbent or horizontal position. Open-air, sea-bathing, flesh-brush, attention to the diet and bowels are powerful auxiliaries. If the affection has been neglected, repeated cupping, and moxas, with acupuncturing, should be applied in succession from the occiput to the coccyx, together with the means just mentioned. The patient should remain in bed on a firm hair mattress, until all pain has been subdued, and even all tendency to a relapse has disappeared. In severe spinal affections, as they are termed, the spinal marrow is found sometimes quite disorganized, a complete mollescence, with more or less purulent matter exterior.

There is a peculiar affection of the cervical vertebræ confined at first to the articulations of the occiput and atlas, and atlas and dentata, which consists in ulceration of the cartilages, ligaments, and bones, ultimately involving the periosteum, the theca vertebralis, the dura mater, the medulla oblongata and brain, and also the pharynx. There is a peculiar expression of pain in the countenance, with dread at moving the head, which inclines generally to one side, and that most frequently the left, and when moved a most acute pain darts to the larynx and scapula of the affected side. The patient experiences most insufferable pain when swallowing a large mouthful, or taking a deep inspiration. These symptoms increase, and excite others fully as distressing, under which the patient lingers for months, when death puts a period to his sufferings. The treatment consists in repeated cuppings and moxas to the nape of the neck, confinement to bed, with the head and neck fixed with the chin-stay, see Fig. 22, Plate DXVI; low diet, and attention to the bowels.

When the long cylindrical bones are attacked with inflammation, their vessels having no latitude to expand and form ulcerative papillæ, become gangrenous, so that the bones are deprived of vitality, and either exfoliate or undergo necrosis. Exfoliation or necrosis seems to take place, according to the exposure or non-exposure of the bones; thus the bones of the cranium exfoliate, while the os femoris becomes necrosed: the tibia, however, either exfoliates or necroses. If the tibia be inflamed, and an abscess occurs superficially to it, the bone generally exfoliates; the inflammation being too violent for necrosis, according to the interpretation of the term by surgical writers, who consider it the death of the old bone, with the formation of a new one exterior to it, whereas, etymologically, it means merely the destruction of the old bone, being derived from νεκρόω, *to destroy*. In such a case, the abscess is to be freely laid open, and the condition of the bone examined; and if it appear divested of vitality, either the nitrate of silver or copper applied to accelerate the exfoliation of the sequestrum, or removed with cutting instruments, the latter of which is preferable. The tibia is sometimes deprived of vitality in extensive ulcers of the leg, in consequence of the periosteum being removed by the ulcerative absorption; in which case granulations are occasionally formed beneath the outer layer of bone, which thus becomes a sequestrum, so that both caries and necrosis exist at the same time. Caries and necrosis also sometimes exist together in ulceration of the spongy bones. When the cranial bones are exfoliating, they are to be gently shaken from time to time, and not rudely removed. When the shaft of one of the long bones dies, a separation takes place between it and the epiphyses; the periosteum inflames, with an accumulation of blood vessels, and thickening of this membrane; and if the inflammation be moderate, these vessels, together with those of the epiphyses, begin to secrete callus, in order to replace the decayed portion; and after the secretion of the new bone has extended from the one epiphysis to the other, the periosteum loses its injected appearance, and returns to its natural colour and density. The new shell now separates from the old bone, and the latter is either forced through the former, or is absorbed. A profusion of callus is at first poured into this new shell, rendering it solid for a time, but afterwards the absorbents make it nearly as hollow as the original. The new bone is at first merely a reddish fluid, next gelatinous, then cartilaginous, fourthly ossific or the phosphate of lime is deposited.

Necrosis occurs chiefly in early life, except when the inferior maxillary bone is affected, which is generally after thirty years of age: it attacks the tibia, os femoris, clavicle, os brachii, fibula, radius, and ulna; and there is a case detailed by M'Donald, wherein nearly all the bones of the body were affected. This peculiar disease of the bones is characterized by inflammation, either acute or chronic, tumefaction of the limb, diffused pain along the bone, ulcerous openings or abscesses, discharging purulent matter, which ultimately become fistulous. There is more or less fever throughout, which at first is inflammatory, and afterwards hectic. As long as the fever is inflammatory, and the limb acutely inflamed, the treatment should be antiphlogistic, with fomentations and poultices; and when these conditions have been subdued, if no ulcers have formed, moxas should be repeatedly applied; but if there are ulcerous or fistulous openings, simple dressings and gentle bandaging; the constitutional remedies being mild nutritious diet, exposure to the open air, and sea-bathing if practicable. The dead bone ought to be left alone as long as the health will permit, unless it has begun to force its way outwards, when it should be removed; but whenever the health begins to sink, the bone must be removed, otherwise amputation will be the only alternative, which otherwise need not be considered, until hectic fever threatens to destroy the life of the patient. During the cure, the patient must be guarded against using the limb before the bone has become properly consolidated, as it is very liable to be fractured. Various absurd remedies are recommended for this disease, as madder, assafœtida, hemlock, &c. Its causes are very obscure; the exanthematous fevers, syphilis, mercury, scrofula, and scurvy, also cold and blows, are considered predisposing; while inflammation is the proximate cause in early life, and obliteration of the blood-vessels in advanced age.

Portions of the cranial bones occasionally die, apparently in consequence of too great a deposition of phosphate of lime obliterating their blood-vessels, the dead part becomes a neutral object, excites irritation, and causes a separation between it and the living portion. When the piece exfoliated is small, it is regenerated by the vessels of the pericranium, dura mater, and diploe; but when very large, is never regenerated.

If we are permitted to continue the analogy, with which we set out, between the bones and the soft parts, they should be subject to the same varieties of tumours, of the truth of which we have not the least shadow of doubt, particularly when affected symptomatically. At present they are confined to Exostosis (from ἐξ, *out*, and ὀστεον, *a bone*), which is divided into various species by different authors, as true, false, periosteal, medullary, cartilaginous, and fungous exostoses, and sometimes acquire considerable magnitude. Exostosis chiefly attacks the dense bones, which are thinly covered, such as those of the cranium, inferior maxilla, sternum, clavicle, ulna, and tibia; although all the bones are occasionally affected. The periosteal exostosis is simply a diseased thickening of the periosteum, forming a tumour chiefly attacking the bones of the cranium and tibia, and occurring generally in the syphilitic constitution; but if not attended to, it commonly involves the bone. Sir A. Cooper considers this affection an osseous deposition between the bone and the periosteum, which adheres firmly to both. In its early stage, it may be removed by the application of the moxa, and the internal administration of the muriate of mercury. Medullary exostosis is when the medulla is primarily affected, and the cancellated structure secondarily; this may be treated in the same manner, but generally requires the knife. The cartilaginous exostosis is when cartilage forms the nidus for ossific deposition, which sometimes grows to an enormous size, and frequently attacks the inferior maxillary bone, requiring the removal of more or less of the sound bone on each side. It also takes place on the sternum and ribs, from whence it may be removed. The fungous exostosis is still softer, containing spiculæ of bone, and being of a malignant nature, acquires occasionally a prodigious magnitude. This is evidently the cellular or laminated osteo-sarcoma of some authors, or osteo-sarcosis, or osteo-malakia, or spina ventosa. It attacks the diploe of the cranial bones, the inferior maxillary bone, and the long cylindrical bones. This exostosis can be only cured by the knife, or amputation. Besides these, there is the exostosis eburnea of some authors, a small hard tumour generally situated on the os frontis, the exostosis petrosa, and the stalactitical exostosis. Hydatids are occasionally found in exostosis. From the magnitude which some of these species of exostosis acquire, they impede the functions of the contiguous soft organs; thus when situated in the antrum, the eye; on the cranium, the brain; on the cervical vertebræ, the spinal cord, and in some cases the subclavian artery; on the inferior maxillary bone, the pharynx and larynx; and on the symphysis pubis, the urethra. Various ridiculous remedies have been recommended for these tumours, and different instruments invented; for example, Jeffray's flexible saw, Machell's chain saw, Graefe's orbicular saw, and Thal's rotation saw.

Mollities ossium, named also malacosteon, is that disease wherein the bones become so soft that they may be twisted or bent in any direction, and in which, being deprived of their earthy property, as if they had been macerated in diluted muriatic acid, their animal constituent only remains. When analysed, the quantity of phosphate of lime amounts only to about an eighth. This disease occurs more frequently in women than in men, and generally about the middle period of life. It is preceded by fever and acute pains in the bones, and the urine contains a quantity of phosphate of lime; it is of long duration, Madame Supiot having lived five years. Its treatment is by attention to the early febrile affection, and afterwards to diet and regimen, exposure to the open air in the horizontal attitude, cold-bathing, flesh-brush and stays.

Rachitis or rickets, which depends also on a deficiency of the earthy property of bones, is closely allied to mollities ossium, but generally attacks the child, even the fœtus in utero. In rickets, the spine and ribs are commonly first affected, and afterwards the long cylindrical bones; the abdomen is tumefied in consequence of the liver, spleen, and mesenteric glands being enlarged; the intestines are filled with flatus, the digestion impaired, the breath fetid and sour, and the stools fetid, acid, and liquid. The respiration is also more or less affected; the head is peculiarly large, with a precocity of intelligence. The singular peculiarity in this disease is, that those children who recover from it in early life and continue strong until adult age, become again affected with it. The bones, after death, are found lighter, flatter, of a red or brown colour, porous, spongy, soft, compressible, and vascular; the cranial are thicker, the long bones thinner, and the medulla is like reddish serum. For the treatment, and a fuller account of this disease, the reader is referred to the Article Medicine, Vol. XIII. p. 29.

Fragilitas ossium may be considered the opposite of mollities, although, according to Boyer, the two diseases are combined. In this, there is a superabundance of the phosphate of lime in the bones, and hence it occurs in advanced life, and in either the syphilitic, scorbutic, arthritic, cancerous, scrofulous, or rachitic constitutions, and therefore symptomatic of some other disease. It is only in the scorbutic and syphilitic cases that any hopes of cure, always very doubtful, can be held out. Saviard details a very remarkable case of this disease, where all the bones after death crumbled under the fingers. Anchylosis, the last remaining disease of the bones, has been already described under affections of the joints, a result much to be desired on many occasions; but it has occurred without any marked increased action, as in the extraordinary case of Clark, detailed in the forty-first volume of the Phil. Trans. where all the bones, from the crown of the head to the sole of the foot, were completely soldered together, and whose skeleton is still preserved in the Museum of the College of Surgeons of Dublin.

This species or variety of wounds has ever been considered an important branch of surgery, either in military, naval, or private practice. These wounds are considered by systematic writers to be essentially different from all other kinds of wounds, and to require a different kind of treatment, as mentioned by J. Bell and Mr. Guthrie; but we contend, that they in no degree differ from contused wounds, and demand precisely the same kind of treatment. If a round stone or bullet is thrown from a sling, as in the days of Celsus, with the same velocity with which a musket bullet is fired, it will inflict precisely the same kind of wound; besides, we know there is no difference between the wound inflicted with an air gun, and that exploded with powder. It would appear that the whimsical notions of the writers on surgery before Paré, who conceived that musket bullets were poisonous, still haunt us. If the above be correct, it is easy to apply the same reasoning with respect to all the variety of gunshot wounds, and it consequently follows, that these wounds differ in no degree from contused wounds caused by stones and other foreign bodies, but in the contusion which the rapidity of the projectile produces. When a person is wounded with a musket bullet within half or quarter musket shot, the missile will most probably pass through the body, and there are then two wounds with a long sinuous tube between them; the aperture made by the entrance of the bullet is of a livid ecchymosed colour, is depressed inwards or indented, and smaller and rounder than that made by its exit, which is rugged and lacerated, having everted edges. These, however, sometimes vary, the exit appearing a mere slit, and in cases where the musket has been close to the wounded person, the entrance is as rugged and everted as the exit; much, therefore, depends on the velocity of the projectile, and the medium of the resisting body. Bullets run most circuitous routes in the body, if their course is diverted by a bone, and the position of the patient when wounded may throw light on this point. Bullets flying with great velocity and striking a part of the body which is clothed, seldom carry the clothes before them; the reverse, however, occurs if they are nearly spent in their career. If, therefore, this projectile has passed through the calf of the leg, or any other fleshy part, there will be little or no pain in consequence of the parts being chemosed, and little or no bleeding, because the blood-vessels are of small diameter and cauterized; but if the bullet is nearly spent, or has been rendered rugged, which is a very common occurrence, there will be some bleeding both from the arteries and veins. The treatment is to confine the patient to bed, and to apply poultices or fomentations to the leg, from the knee downwards, with the view of moderating or subduing the consequent inflammation, and of restoring the contused part to a healthy condition. The chemosed tube must suppurate and granulate to a certain extent, consequently poultices correspond most with the theories, opinions, principles and practices of all writers, even of Mr. Guthrie, who condemns them. After all inflammation has been subdued and suppuration established, the wound should be syringed with cold water, and simple dressings, and gentle bandaging applied. For the after treatment the reader is referred to ulcers. The diet is to be regulated according to circumstances. Sometimes only the part which is first struck with the bullet suppurates, being the most contused; while the rest of the tube unites by the first intention. If pieces of the clothes are carried into the wound, and far from either aperture, they should be left alone until suppuration is completely est.blished; but if near either of its apertures, they should be extracted. In some cases they are carried before the bullet, so as to resemble a purse, and are then removed with facility along with the bullet. The course of the bullet should, if possible, be ascertained, in order to calculate whether any important artery is wounded, or bone fractured, in which case the patient, by endeavouring to recollect the attitude he was in when wounded, may facilitate our inquiry.

According to the velocity and ruggedness of the missile, will an artery bleed immediately, or at some more remote period; but in the majority of instances, the hemorrhage is primary, and if it be the principal artery of a limb, so much is instantaneously lost as to produce syncope; if the surgeon is on the spot at the time, a tourniquet should be loosely applied, the artery cut down upon, and secured above and below the wound, but at a little distance from it, to avoid its being involved in the inflammatory action of the wound, which must follow. But if the surgeon is not at hand, and inflammation has begun, a tourniquet must be loosely applied, and an assistant appointed to watch until sloughing and suppuration have taken place; and if then secondary hemorrhage ensues, the artery must be secured; but secondary hemorrhage is so rare, that not above four in the 1000 are attacked with it.

In musket-bullet wounds of the hand or foot, the bones of these are generally fractured, and in the treatment, we must always keep in view, that gunshot wounds are more contused than others. The other bones of the extremities when struck with musket-bullets, are also very often fractured, and commonly splintered, and require the same treatment as described under fractures, bearing in mind that immediate amputation is more necessary in compound fractures from gunshot, than from any other causes. When a musket-bullet runs close beneath or centrad of the fascia of the arm or leg, it not unfrequently produces erysipelas phlegmonodes, which, besides the treatment already recommended for such, often requires the orifices of the wound to be enlarged. Wounds of the joints generally demand immediate amputation, for such a degree of inflammation and fever with suppuration follow, that the individual sinks under it, and there is no opportunity for secondary amputation.

When a musket-bullet is arrested in the body, and not situated in the contiguity of a vital or important organ, it ought to be abstracted wherever that is practicable, even if lodged in a bone, and as it generally prevents the wound healing, and produces inflammation, suppuration, and sinuses, and may prove an annoyance to the patient in after life, sometimes causing lameness if situated in the leg. All the bullet forceps and probes invented are of little or no avail, the finger in many cases being only admissible: the limb of the patient should be laid in the attitude in which it was wounded, and the left hand placed opposite the wound, into which the fore-finger of the right hand is to be inserted. If this fails, the patient should be requested to move gently the limb in various ways, and the seat of the bullet may by this means be ascertained, and removed, due attention being paid to important objects, for when situated near a large blood-vessel, it ought to be allowed to remain. If the bullet which continues in the body is lodged in cellular or muscular substance, and produces no immediate irritation, a membranous cyst is gradually formed around it, which adheres so close as to be with difficulty detached in a few months afterwards; and when situated close to a bone, the periosteum forms an osseous pouch. Sometimes they gravitate down a limb before becoming thus imbedded, and occasionally excite the formation of abscesses at a later period; at other times they excite so severe a pain that they compel the patient to have them extracted. From the earliest records of surgery there have existed much diversity of opinion and discussion, upon the propriety and manner of extracting bullets and other foreign bodies on the receipt of a wound. With respect to dilatation, it is now an axiom in British military surgery, never to dilate, unless necessity requires it.

Wounds inflicted by large shot, named large round, double-headed or bar-shot, grape, cannister, langrel, langrage, and shells, only differ from those caused by musket-shot, in the greater destruction of the part, and the more violent constitutional derangement; for in musket-bullet wounds, unless the head, knee-joint or some important organ be injured, there is trifling constitutional derangement on receipt of the wound. In severe wounds from cannon-shot, there is a dreadful concussion of the nervous and circulating systems, the patient has a pallid anxious countenance, a cold clammy skin, a feeble pulse, and most acute pain. In such a condition of the constitution, and supposing the knee-joint the seat of the injury, amputation cannot be performed any more here than in compound fractures of the bones forming this joint; and if the patient has lost much blood, there will be probably convulsive motions of the limb, and even of the whole body, together with irritability of the stomach, hiccup, wavering of the intellect, and extremely feeble voice, and a pulse scarcely perceptible. These constitutional symptoms, however, are said by Dr. Quarrier not to be always present. When the patient rallies, which will be after a longer or shorter time, according to the extent and nature of the injury, and the idiosyncracy of his constitution, for no precise period can be mentioned as described by authors on this subject, amputation should be performed. The rallying of the patient is characterized by pain, and a sensation of heat in the wound, a warmth of the skin, a quickness of the pulse, and thirst. There is another reason against immediate amputation, when the patient has been exposed to external cold after the receipt of the wound, for he then becomes in a measure frost-bitten, and requires to be thawed. On the propriety of immediate amputation, according to the hitherto received idea of this expression, there has existed much diversity of opinion from the early part of the sixteenth century. Dr. Quarrier and the other medical staff who were at the battle of Algiers, consider the expression "immediate" to apply to amputation performed as soon after the receipt of a wound as possible; while it had been formerly applied to the operation, whenever the system had rallied from the shock received by the wound, and contradistinguished from amputation performed when suppuration had taken place. The advocates for primary amputation, or when the constitution has rallied from the shock of the wound, are Du Chesne, Wiseman, Dionis, Le Dran, Ranby, Faure, De la Martiniere, Morand, Van Gescher, Pott, Schmucker, Boy, J. Bell, Dupuytren, Sanson, Begin, Larrey, Graefe, Guthrie, Thomson and Hennen. The advocates for secondary amputation, or when suppuration has taken place, are, Le Conte, Boucher, Bagieu, Bilguer, Percy, Sabatier, Mehee, and J. Hunter. Drs. Dewar and Quarrier, and Mr. C. Hutchison, recommend amputation instantaneously after the receipt of the wound, and contend that constitutional symptoms do not take place immediately; indeed the latter surgeon treats with contempt nervous commotion occurring to British seamen or soldiers: so that the only way of reconciling the opposite sentiments of Drs. Dewar, Quarrier, and C. Hutchison, with those of Drs. Hennen and Guthrie, is, that in the navy a man is brought instantaneously after being wounded to the surgeon, before constitutional symptoms have had time to appear, which, says Dr. Hennen, is a much earlier opportunity than any army surgeon can possibly enjoy; whereas a few minutes at least must elapse before the army surgeon can arrive at the wounded soldier, however fleet or active his ambulance may be. It is to be feared this instantaneous amputation was performed indiscriminately in the reign of Louis the XIV., which from its fatality alarmed him and all France. There appears two conditions of the constitution after gunshot wounds, the one wherein no commotion follows, as in the seamen at the battle of Algiers; and the other wherein nervous agitation exists, as occurred to the duke of Montebello, narrated by Larrey: that in the former, amputation may be instantaneously performed; while in the latter, some time must be allowed to elapse; and even both Mr. Guthrie and Mr. C. Hutchison recommend these methods of practice. In amputation of the upper or proximal third of the thigh, the operation is allowed by all writers on this subject to be seldom or ever successful; and many cases are on record of those wounded in this region dying in a few minutes, before amputation could be performed.

In gunshot wounds, the brain, the lungs, and the liver are often injured when the wound is quite remote. See Larrey's *Account of General Caffarelli, Duke of Montebello, &c.* The wind of a ball, as it is termed, is now completely established to depend on the projectile striking the body, but not producing any apparent injury of the skin; many interesting cases of which are related by Schmucker, Hennen, and Guthrie.

Tetanus, which has been already described in the article MEDICINE, Vol. XIII. p. 16, supervenes more frequently to wounds made by pieces of shell, langrage, and splinters of wood, than any other kind of missiles, and is then termed traumatic. See Larrey's *Military Memoirs*, and Sir J. M'Gregor's *Observations on the Peninsular War*.

Barons Percy and Larrey invented flying *ambulanee*, that of the latter great surgeon being evidently the better; it consisted in an admirable arrangement of surgeons, assistants, soldiers, officers, instruments, and medicines, all at a moment's command, to afford immediate assistance to the wounded, even while under the fire of the enemy. They followed the advanced guard, and the instant a soldier was wounded, he was dressed, or had his limb amputated on the spot, and then put into a light covered wagon, which conducted him to the hospitals in advance. The number of people attached to each division of ambulance amounted to 113, and consisted of one staff surgeon, two staff assistants, twelve assistants, two of the latter of whom did the duty of apothecaries; a lieutenant to command the economy of the division, but under the orders of the staff surgeon; a sub-lieutenant, who was inspector of the police of this division; a serjeant-major; two serjeants; a trumpeter, who also carried the instruments; twelve horse soldiers, among whom was a farrier, a shoemaker, and a coachmaker; an inferior or deputy commissary; two provision searchers; three corporals; a drummer, who also took charge of the surgery; twenty-five soldiers; twelve light cars or covered wagons capable of being driven on all kinds of ground, with the exception of a very steep hill; four heavier carriages. The light cars were mounted, some on two, and others on four wheels.

In the explosion of gunpowder, an individual is commonly scalded as if with boiling water, but occasionally so severely injured as to be instantly deprived of life. Burns differ in the extent of the surface injured, in the depths of the parts destroyed, and in the vitality of those parts; these three being equally destructive. In cases where the injury is confined to the integuments, there is no difference between it and that inflicted with boiling water, oil, or lead, or that caused by sliding down a rope from a height, or being grazed by falling from a height along a stone wall; one and all of these evidently may be referred to contused wounds, and since they have no mysterious character, require the same kind or mode of treatment; for on no subject of surgery does there exist more contrariety in the treatment, from the high authority of Dr. Thomson to the whimsical doctrines of our worthy citizen Mr. Cleghorn the brewer. Burns or scalds should be treated like contused wounds; and when they become ulcers, like these affections, and if they advance to mortification, the same as it; for according to the extent of injury do they inflame, suppurate and mortify, and involve the constitution. The practice long pursued in the Greek islands, in America, and now in this country, of enveloping the scalded or burned surface with raw cotton, or the wadding employed in ladies' dresses, is truly an invaluable and soothing remedy. It seems to act by excluding the external air, in the same way as when vesication takes place and left alone, no pain is felt, but whenever the vesicle is freely laid open, the pain is most severe: in vesication, therefore, a small puncture should be made to evacuate the serous fluid. Powdered chalk, and flour out of the cook's dredge box, so ably advocated at present, act on the same principle as the cotton. In extensive scalds or burns, there is generally great prostration of the vital powers, and if the patient rallies, violent reaction follows; occasionally wild delirium and coma; at other times an oppressive difficulty in breathing; in other instances inflammation of the mucous membrane of the alimentary canal, in others, hydrocephalus supervenes. When the grains of gunpowder are lodged in the skin of the face, they may be removed by a needle. In the healing of extensive burns, great attention should be paid that no unnatural adhesions or contractions of the integuments occur, as the union of the fingers, or of the chin to the neck, or of the latter being twisted to one side. The eye-lids, particularly the lower, is occasionally allowed to adhere to the cheek so as to form ectropium.

Amputation, from *amputo, to cut off*, is one of the most common, simple, and, however paradoxical, one of the most difficult operations in surgery: for, to execute it scientifically and dexterously, requires a most intimate knowledge of the relation of the arteries to the veins, nerves, and muscles. This operation is performed, when a member of the body is so injured or useless, as to be of no service to the individual, and the surgeon is placed in a most critical and perplexing situation, and requires a firm mind to decide, whether or not nature, if assisted by art, might not restore the use of the limb, a consideration of such importance to the individual, that amputation ought never to be performed without the deepest reflection. In private practice, there are all the various comforts of life; but in an hospital, there is extensive suppuration and gangrene staring the conscientious operator in the face; on board of ship, there are the inconvenience of the elements to contend with, and the distance from port; and on the field of battle, there is the exposure of the wounded to the inclemencies of the weather, the transportation to a house or hospital, the breaking up of that hospital on the approach of the enemy, and a thousand incidents at once embarrassing and perplexing; so that, too often, the most fixed axioms in surgery are overturned by these fortuitous events. We have already stated under mortification, that gangrene resulting from mechanical causes, or traumatic gangrene, requires amputation: and it may be set down as a general law, to amputate whenever a joint is exposed together with fracture of one or more bones entering into the formation of that joint, or the main artery of a limb so injured as to cut off its circulation, or the limb extensively contused and lacerated: in short, in such a condition, that it is the surgeon's conscientious belief and conviction, that no other means than this will save the limb, or probably the patient's life. But such a variety of opinions exist on these points, that much must be left to the discretion of the surgeon. Compound and mutilated fractures afford other grounds for amputation, and when these injuries occur from musket-bullets or grape-shot, the bone is generally much shattered, and the fracture very oblique; hence in such cases there can be no precise rule. When a limb is torn off by machinery or cannon-shot, amputation is performed, in order to make a clean and neat stump. White swelling of a joint in the last stage, large exostosis of a bone impairing the health by its bulk and weight; osteo-sarcoma attacking the bones of the extremities; caries and necrosis affecting these bones and injuring the health, or producing luxation of a joint, with anchylosis and deformity, require this operation. Fungus hæmatodes, or medullary sarcoma affecting the extremities, or even other species of sarcoma incapable of extirpation; old ulcers of the leg or arm, affecting the bones or articulations, or producing hectic fever; deformity of a limb itself may require amputation. From these cases it appears, that a limb should be amputated, when there is no prospect of saving it; and when the disease threatens to endanger the patient's life; when the limb is cumbrous and useless, and that its removal would be of essential service to the individual.

In extensively contused and lacerated wounds, in compound fractures, in compound luxations, in cases where the arterial trunk of the limb is destroyed, and where the limb is torn off, amputation should be performed whenever the system has rallied from the shock of the injury. For, at first, the patient is exhausted, cold and lifeless, and requires some minutes or even hours, before the nervous and circulating systems regain that degree of strength to bear such another shock; because in so great a dismemberment of the body as a thigh, the patient must be overcome, even granting that not a drop of blood were spilt. If therefore amputation be performed too early, one shock is added to another, and the individual is destroyed. When the patient has rallied from the shock of the injury, his skin becomes warmer, the pulse beats stronger, and he complains of thirst; and if this critical period be overlooked, or if the surgeon does not arrive until it is passed, inflammatory action has commenced, and then the operation must be deferred until all inflammation is subdued. Afterwards, when suppuration is completely established, and if then there appears no prospect of saving the limb, it should be amputated: and should the inflammatory action run on even to mortification, this operation must also be performed. In cases of caries, necrosis, fungus hæmatodes, and tumours of the bones, if the patient has just arrived from a journey, or has any degree of fever, some days of repose should be allowed him before operating. Prior to the use of the ligature, a limb was either cut off with a red hot knife, or the stump seared with a red hot iron or boiling oil; and before Petit's tourniquet was invented, a general circular compression was employed to compress the arteries. Objections are urged against the tourniquet, but if it is properly applied they are fallacious. This instrument, delineated in Fig. 3 of Plate DXVII, ought to be always used in amputation, when a large artery is to be divided. A bandage of calico four inches in breadth is firmly rolled up until it is about two inches in diameter, which is to be applied in the course of the artery on the proximal portion of the limb, sufficiently distant from the point where it is to be amputated, and the roller fixed to the limb with a bandage sufficient to surround it; the screw of the tourniquet is then placed on the roller, and the buckle on the outside of the limb. The screw is not to be tightened until the operator has the knife in his hand, in order that the artery and other textures may be compressed for as short a period as possible. The deviation of the superficial femoral artery, which occurred lately to Mr. C. Bell, when securing it for aneurism, is a satisfactory evidence of the necessity of a tourniquet, and of not trusting to the compression of the artery by means of the fingers of an assistant, who may become agitated or seized with sickness, fainting, cramp, or epilepsy.

There are various ways of performing amputation. In the days of Celsus it was done by the skin being previously retracted, and a circular incision made at once to the bone, from which the soft parts were detached and drawn upwards, and the bone sawn, which in our opinion is the best mode of performing the circular amputation, and, if applicable any where, to the middle of the arm. Paré and Wiseman operated in the same way, but used stitches to the wound, as practised by some modern surgeons, and Wiseman laid aside the use of retractors, which are formed of linen, leather, or tin, to keep the soft parts out of the way of the saw. The flap operation below the knee-joint was next invented by Lowdham. J. L. Petit made the double circular incision of the soft parts, the first through the integuments, the second through the muscles of the bone, after the integuments had been drawn upwards; and this is the method commonly adopted when the circular operation is preferred. Ravaton made a circular incision to the bone, then one on the fore part and another on the back part of the limb upwards or proximad for four fingers breadths detached these flaps from the bone, which he afterwards sawed. Vermale operated by transfixion, with a long bistoury, which is the mode followed by Desault, Lisfranc, and others. Various instruments and other inventions were contrived by Verduin and others, to supersede the necessity of ligatures to the divided arteries, and, strange to tell, some of these are at the present day used in Germany by Dr. Koch. Marquest de La Mothe seems to have been the first who carefully drew out the arteries from the contiguous veins and nerves with the forceps, before securing them with the ligature, and Alanson with the tenaculum. The forceps are best for large arteries, or arteries surrounded with loose cellular substance; the tenaculum for small arteries imbedded in the muscles, and the curved needle when the latter are indurated or converted into cartilage. Louis invented the division of the loose muscles in the first incision, and in the second those adherent to the bone, a mode much used by those who recommend the circular incision. Allanson, after the circular division of the skin and its retraction, attempted to make a circular oblique incision of the muscles upwards or proximad, so that when the bone was sawn, the stump should present a concave cone, the apex being the truncated bone; but in effecting such a form of stump, he must clearly have deceived himself, for in no other way than by two or three circular sweeps in succession can a concave cone be accomplished, as is clearly proved by Marten, Richter, Hey, Graefe, and Langenbeck. Yet this mode of forming a concave cone is talked of by the majority of systematic writers. Kirland cut off a piece of skin at each angle to prevent puckering.

Having made these observations on the different modes of amputation hitherto in use, we shall describe that practised by ourselves, to illustrate which the thigh is selected, that being the extremity to which the preceding modes chiefly apply. The patient being placed as usual on a low firm table, with the leg held by an assistant, and the tourniquet applied as directed, the operator stands on the left side of the patient, and when all is prepared, the screw of the tourniquet is tightened, and the operator with the knife delineated in Fig. 2 of Plate DXVI. makes a lateral incision nearly transversely to the bone on the outer or fibular aspect of the thigh, its direction pointing a little obliquely upwards or proximad, as represented in Fig. 3 of Plate DXVII. then with the same sweep of the knife he cuts upwards or proximad along the same side of the bone, to an extent equal to the diameter of the limb; then an assistant takes hold of this flap when cut, and a corresponding flap is then made, on the inner or tibial side of the thigh, which is also held by the assistant, who now gently retracts them both, since, if any bleeding occurs, he can thus easily command it. The surgeon then divests the bone of any muscular fibres at the root of these flaps, and saws it. The arte ries are next secured and both ends of the ligatures cut off. Whenever the trunk of the femoral artery is secured, the tourniquet should be suddenly slackened, to enable the operator to find the smaller branches, and may be tightened again or not, as necessity requires. The instant all the arteries are secured, it should be completely loosened. The wound is then cleaned with warm water, and if the weather be sultry, and the patient flabby, it should be afterwards sponged with cold water. In summer, the wound should be stitched, and no bandage applied; while in winter, a roller is brought loosely down along the thigh from the loins until the near end of the bone, when the flaps are approximated by adhesive straps, the wound covered slightly with two pieces of lint placed across, and the roller continued down to the end of the stump, and afterwards a little upwards. With the tourniquet loose around the limb, the patient is carried to bed, the stump placed on a pillow, and left uncovered, and a draught containing 50 drops of laudanum given. A diagram, representative of this mode of operating, is given in Fig. 3, Plate DXVII. This mode of operating seldom requires more than thirty seconds, and is preferable to transfixion, on the following grounds:—The flaps are more easily made, are fuller and thicker, and can be lengthened, if they appear too short, after the same manner of incision, and a third flap can scarcely occur. When sawing a bone, the saw should be swept lightly from heel to point, and no weight or pressure whatever used. In all operations the patient should take a dose of physic the preceding day, and after amputation, he is to be kept quiet, on low diet, with an assistant at his bed side for at least thirty hours, in case of primary hemorrhage. As for secondary hemorrhage, we have seen it vary from two to thirty days. When hemorrhage occurs, the bandage should be examined, and if found in the least degree tight, ought to be instantly loosened, as pressure is very liable to check the cutaneous venous circulation, and thus produce venous hemorrage; and this occasionally arises not from the bandage being applied too tight at first, but from the wound becoming tumefied. If the slackening of the bandage does not stem the bleeding, and the latter appears to be trifling, cold water, with a little vinegar in it, should be used; but if profuse, or not stopt by this means, the wound must be opened, and the bleeding arteries secured with ligatures, or sponge applied in the form of compression. If the bleeding takes place within the first two or three days after the operation, it is then from small arteries, but if afterwards, it is most probably from the trunk, in which latter case, the artery high up in the thigh must be secured, a plan superior to another or secondary amputation, as recommended by some authors. Spasmodic action of the muscles sometimes occurs to such a degree, as to require the stump to be fastened down to the mattress by a broad strap, and large opiates administered internally. Inflammatory fever occasionally supervenes, and requires active treatment, even in the emaciated constitution. As suppuration results in forty-eight hours, the wound should be dressed on the third day after the operation in summer, and fourth in winter, and not deferred until the eighth, as recommended by some. The straps of adhesive plaster should be most carefully removed at both ends, and one substituted before another is detached, and the clean bandage rolled downwards to the end of the bone, before their reapplication. Unctuous dressings are to be applied. Warm water ought to be injected into the wound, if there are any cysts or abscesses, and should be gradually reduced to the ordinary cool temperature, at each daily dressing. The diet should be moderate, as long as there is any increased action, and ought to be carefully augmented, but if the suppuration be profuse, it may then be nourishing. In amputation of so large a member as that of the thigh, the patient should be kept in the horizontal position, for at least a fortnight, and even then be allowed very little exertion. If bleeding has occurred after the operation, and so filled the wound that its lips are opened, and the bone has been deprived of its periosteum during the operation, there will not only be protrusion of it, but death of the bone. If the latter be the case, the protruded portion should at once be sawn off, and if the former, or simple protrusion, this step must be left to the discretion of the surgeon. We would recommend the same little operation to be at once adopted. After amputation, the patient should walk upon crutches for at least six months, before attempting to walk upon a wooden or cork leg, in order that the stump may be thoroughly consolidated and strong. Our limits will not permit us to give a description of the individual amputations; for them the reader is referred to Lizars's *Anatomical Plates.*

Incised wounds are made with a clean sharp instrument, although a very blunt one, by no means clean, when moved with velocity, may inflict a very cleanly incised wound. Whatever be the extent of such wounds, they are to be gently approximated with adhesive straps, compress, and bandage; but so prone is the scalp to inflammation, which generally assumes the erysipelatous type, that even the adhesive strap is occasionally inadmissible. In such cases, either poultices alone or combined with the strap are to be applied. In every case, more or less internal excitement is to be dreaded, so that the patient should remain quiet, on moderate diet, and pay attention to his bowels, and if the leat degree of headach follows, venesection ought to be performed. In injuries of the head, blood-letting should be prescribed with as much freedom as a dose of salts.

In lacerated wounds, whatever may be their extent, and however insulated may be the scalp, the part, if possible, should be preserved. This plan was followed in the time of Celsus, but went into desuetude until Paré revived it, and again was laid aside until the day of La Motte, for in the Hotel Dieu the lacerated scalp was dissected off by Petit and others. Cases of prodigious portions of the scalp, which had been torn off and reunited, are to be found in the works of Paré, La Motte, Hill, Pott, J. Bell, and Abernethy. In all cases of lacerated scalp, the whole hair of the head is to be shaved off, and the portion which is torn to be cleansed of blood and dirt, and carefully replaced, and retained in position by adhesive straps, gentle compression and bandage, or a handkerchief. The latter, when folded triangular, is named *kerchef* or *couvrechef*, when folded square and applied, is termed *grand couvrechef*. Poultices, although condemned by some writers, will be found of much more service than cold lotions in those cases where inflammation of the scalp takes place. In lacerated wounds, there is always such a degree of injury done to the bone or its contents, that we must keep in view the most active antiphlogistic treatment. Wounds of the scalp are fully more dangerous than those of the brain, so that even after the wound is healed, the most rigid attention should be paid to diet and the bowels, and all exciting causes avoided for some time to come. Suppuration is very frequently consequent on this injury, and the matter requires to be most freely evacuated. Occasionally portions of the scalp slough, and require removal, but never until the part has completely sphacelated.

The same treatment is to be adopted in contused wounds, accompanied with laceration of the scalp, or lacerated wounds attended with contusion. In the latter case, we must anticipate suppuration and sphacelation, and poultices are more necessary. Lacerated and contused wounds frequently lay the foundation of suppuration of the membranes of the brain, and even of the brain itself.

Punctured wounds of the integuments of the cranium are subdivided by Pott and the majority of surgical writers, into those of the cutis, of the subcutaneous cellular tissue, the tendon of the occipito-frontalis, and the pericranium, and they have attempted to assign symptoms characteristic of each, with an appropriate treatment, "opinion évidemment née des applications anatomiques," says Desault, "plutôt que de l'observation de la nature." And with equal truth, says J. Bell, "the integuments of the skull are essentially connected as a whole, having one continuous circulation, and having their disease in common." In punctured wounds, therefore, there is commonly erysipelatous inflammation, with more or less affection of the brain and its membranes, accompanied with general fever, in which the hepatic and gastric organs are affected. The treatment consists in general and local blood-letting, leeches being applied to the parts adjoining the wound, and the temporal artery, or external jugular vein should be opened ; fomentations and poultices afterwards to the scalp, brisk cathartics, warmth to the feet, blisters to the nape of the neck, low diet, and confinement to bed in a darkened chamber. If there be much tension around the wound, the expansive tendon of the occipito-frontalis muscle should be divided transversely ; and it may be even advisable to take into consideration the propriety of making several incisions in the erysipelatous scalp, as mentioned under erysipelas phlegmonodes. When suppuration follows punctured wounds of the scalp, free incisions ought to be made to evacuate the matter, which, on some occasions descends to the eye-lids, and even beneath the fascia of the temporal muscle down to the mouth.

The integuments of the cranium are frequently so bruised by a blow, that the blood is injected chiefly into the cellular tissue, between the cutis and occipito-frontalis muscle, communicating to the fingers of the surgeon the feeling as if a portion of the bone was depressed ; whereas it is mere ecchymosis, or, suggillation, according to J. Bell. There is a tumour commonly the size of a crown-piece, hard in its circumference, from the cellular tissue injected with extravasated blood, which gradually declines towards the centre, where the bone is distinctly felt through the blood, which here remains fluid. In such cases, all that should be done, is either to leave this blood to be absorbed by the vessels, or to apply warm discutients. If a considerable quantity of blood is effused, it is liable to destroy the connection of the pericranium with the bone, and even the bone itself; therefore, all such cases should be carefully watched, and if the effused fluid does not diminish in a few days, but continues to increase, or begins to excite headach, &c. a puncture should be made to evacuate it, and the condition of the bone examined. See cases detailed by Hill and J. Bell.

When a blow is inflicted on the head so as to stun the individual for a time, it frequently lays the foundation for irreparable evil. In a short while, he recovers his faculties and pursues his ordinary occupations for a week or two, when he begins to complain of headach, listlessness, thirst, loathing of food and nausea, passes restless nights, feels his face flushed, his eyes tender, swollen and watery, with contracted pupils, and which feel pained on looking at the light of a candle or a fire. He is attacked with rigors, cannot articulate distinctly, his tongue quivers and will not obey the voluntary powers. A small tumour appears where the blow was inflicted, feels tender on pressure, which, if severe, produces a convulsive action. He now becomes despondent, peevish, fretful, oppressed and sick during the day, muttering to himself in a lethargic state, and when roused, appears stupid, immediately relapsing into the same comatose condition. The pulse is quick, feeble and hard, the tongue foul, the skin dry with flushed countenance, and red gummy swollen watery eyes, the urine scanty and high-coloured, the hands and the tongue tremble, the bowels are constipated, and during the night he is delirious. He then becomes comatose, has a dilated pupil, occasionally stertorous breathing, delirium, and sometimes convulsions, when death closes the scene. On dissection, the puffy tumour contains a sanious fluid, the pericranium is separated from the bone, the latter of which is of a white colour, and has a dry appearance, no blood-vessels being present. Underneath the bone, matter is also deposited, and the dura mater separated from the bone is ulcerated, presenting a dirty yellowish green colour, while the brain itself is soft and also ulcerated. These fatal effects are all attributable to the bone in the first instance having been so contused, that its circulation is destroyed, the pericranium and dura mater separated from it, a slow degree of inflammation is excited, which terminates in suppuration. The death of the bone sometimes follows lacerated, contused, and punctured wounds of the scalp, as proved in J. Bell's *Principles of Surgery*. It is only when the bone is contused that such fatal events occur, for otherwise it is very tenacious of life, being highly vascular, and having three sources of nourishment, the vessels of the pericranium, those of the diploe, and those of the dura mater; and when cut and replaced, readily unites. The dura mater is a sero-fibrous membrane possessing little or no sensibility, for acids and cauteries have been applied without producing pain, and like bone enters slowly into inflammatory action, but then that action is with greater difficulty checked. These insidious symptoms are by no means regular in the period of their occurrence after an injury, varying from weeks to months; but whenever any of them do present themselves, we should instantly take alarm and apprehend the most dismal consequences, for too often the patient is beyond the reach of help. The most diagnostic symptom is the rigors, which are occasionally very slight; we are therefore immediately to confine our patient to bed, and pursue the most active antiphlogistic treatment. And if the insidious inflammatory symptoms are not subdued by such means, but on the contrary becomes comatose with rigors, with or without a puffy tumour, the operation of trephining should be performed, in order to give exit to the matter; for a puffy tumour is not always present to guide us. See Abernethy's *Surgical Works*, vol. ii. p. 27.

The patient ought to be laid on a low firm table, with the head on a thin pillow; a tripod or crucial incision is then to be made through the integuments forming this puffy tumour, the contents of which are foul and sanious, and the bone dry and of a yellowish white tinge; the crown of the trephine represented in Fig. 17 of Plate DXV. is then applied to this dead bone, with the central pin elongated, and cautiously and lightly worked with semicircular turns, first standing on the one side of the table and then on the other, until the teeth of the saw have made a distinct circular groove. The central pin is then to be retired and fixed, and the crown of the trephine cautiously turned in the same manner, examining very frequently the depth to which the instrument has sawn, with a quill cut like a pen, and brushing away the dry and bloodless dust from the teeth of the instrument and the groove in the bone. If the groove be attentively examined, the inequality of the bone may be observed, and whenever one point appears sawn through the outer table, diploe, and the least of the inner table, the elevator delineated in Fig. 18 of Plate DXV, should be tried. The operator must then saw those points of bone which remain entire with short turns, and use the elevator from time to time. If the circular disc remains, it is to be removed with the forceps. If any spiculæ of bone remain so as to injure the dura mater, they are to be removed with the elevator, but the surgeon should not be too fastidious about these spiculæ. Some use a perforator before applying the crown of the trephine, but this is seldom necessary. As this operation is generally done on patients in an insensible state, and as it is attended with the greatest danger, there is no cause for expedition. It is one of the operations in surgery whose success depends more on cautious delay than celerity. After the removal of the circular disc, the dura mater will be found coated with matter green and ulcerated, and if the matter does not exude out at the trepan hole, it ought to be gently syringed with warm water; and if no relief whatever has been obtained, but the symptoms still continue, this membrane should be freely incised across with a bistoury; and even then, if the symptoms are not sensibly alleviated, an incision ought to be made into the brain itself. "*Melius esse experir remedium anceps quam nullum;*" or "can the surgeon be said to destroy by his operation, a patient who is declared past all hope?" For confirmation of this practice, the reader is referred to Hill's *Cases in Surgery*, and to the Lancet, No. 117; also to Wiseman's and J. Bell's works.

The repetition of the operation of trephining is now never adopted, as was proposed by Lassus, and performed on the Count of Nassau in King William's wars no less than twenty-seven times; but it may be done on any part of the cranium within reach; the superior longitudinal sinus and other objects forming no interdicted points, as in the days of the ancients, but only points of caution. On some rare occasions, blood and even pus have been found effused in the diploe. See J. Bell's *Principles of Surgery*, vol. ii. p. 431. After the operation of trepaning the patient should be bled and treated antiphlogistically, and for months afterwards he ought to avoid all exciting causes. The flaps of the integuments are to be put down and managed lightly with simple dressings. Suppuration of the dura mater occurs in caries of the frontal and parietal bones in corona veneris, and even sometimes spontaneously, as exemplified in the case detailed in Abernethy's *Surgical Works*, vol. ii. p. 108. Blows or contusions of the cranium produce sometimes only an exfoliation of the bone, which, though slow in its progress, never is free from danger. It has been proposed to replace the circular disc, but this is perfectly inadmissible in disease.

After the operation of trepaning, phrenitis is a common occurrence, and hence the reason of directing bloodletting after this operation on all occasions; for the nature and treatment of this affection, the reader is referred to the article MEDICINE, p. 720; and we have only to observe that we prefer arteriotomy to phlebotomy, apply cold cloths to the head and warmth to the feet, blisters to the nape of the neck, but never to the crown of the head, and that it is very difficult to produce syncope in affections of the brain. Acute inflammation of the brain, if neglected, generally soon terminates fatally, either by general effusion between the arachnoid membrane, and pia mater, and into the ventricles; or by effusion of coagulable lymph, or suppuration of the tunica arachnoides and pia mater. But cases are detailed of its terminating in blood and even gangrene.

After this operation, also, if the dura mater be injured, a fungous growth of the brain sometimes shoots forth, termed hernia, or fungus cerebri, which excrescence depends both upon a healthy and diseased condition of the brain; springing up with surprising rapidity in the latter state of this organ. This fungous growth is also consequent on fracture of the cranium with depression, wounding the dura mater, or on ulceration of the dura mater, or on concussion of the brain. For an example of hernia cerebri arising in a healthy condition of the brain, the reader is referred to Hey's *Pract. Observ. in Surgery*, case of Boy Topham; and for cases depending on a diseased condition of the organ, to Hill's *Cases in Surgery*, J. Bell's *Principles of Surgery*; Abernethy's *Surgical Works*, Hennen's *Military Surgery*, and Thomson's *Report on Belgium*. In the healthy condition, the pia mater is wounded, and the tumour has the natural appearance of the brain, merely more vascular, and is evidently analogous to fungous or exuberant granulations of other parts of the body; while in the diseased, it is generally of a grayish colour with coagulated blood, and a turbid serous fluid around, and strangulated at its root, and resembles fungus hæmatodes of other textures. In the latter, it is preceded and accompanied by more or less stupor, slowness of pulse, dilatation of the pupils, slight strabismus, and paralytic affection of the mouth, the symptoms in many cases precisely resembling those of compressed brain; and in some instances, by symptoms of inflamed membranes of the brain, and particularly delirium. The treatment of this tumour by the authors referred to is very variable, but what we have found most beneficial is the free use of the lancet to remove the cause, and whenever the fungus appears above the level of the surface of the brain, to pare it off with the scalpel, and apply the most light and gentle dressings possible; to evacuate any matter lodged beneath the tumour; to remove all cause of strangulation at its root; to put the patient on low diet, in a darkened chamber, and to keep his bowels very open. If hemorrhage occur, exposure of the surface to the air generally checks it, otherwise the actual cautery should be applied: the bleeding is generally more beneficial than injurious. In the fungus originating from a healthy state of the brain, low diet, open bowels, perfect rest and cutting off the luxuriant growth, almost always succeed; but if it continues to sprout forth, bloodletting should be adopted.

Compression of the brain may be produced by the effusion of matter, blood and water, or serum; by the congestion of blood in the vessels, and by depression of the bone. This state of the brain is indicated by loss of sense and voluntary motion, the individual being unable to move a limb, being blind, deaf, dumb, and without the faculty of smelling or tasting; a slow heavy pulse, stertorous breathing, and dilated pupils, because the fountain or centre of nervous energy is suspended in its function. The depression of the bone is always the result of external injury, and is of a greater or less extent, according to the severity of the blow. Simple fractures of the cranium are in themselves productive of no evil, and occasionally take place on the opposite side of the head to that where the blow was inflicted, and sometimes produce a circular fracture of the entire cranium, and are often the cause of hemorrhage and inflammation. When a fracture occurs in the base of the cranium, some of the blood-vessels are generally wounded, producing extravasation, that leads to fatal events, and not unfrequently blood issues from both the nostrils and ears. When the frontal sinuses are simply fractured, and the nose blown, the air escapes into the cellular substance of the forehead, rendering it emphysematous.

Depression of the bone is more or less serious, according to the depth of depression, and the spiculæ into which the bone has been broken. Our guide in the treatment of depressed bone should be the symptoms of compression of the brain, for there are numerous cases on record in the works of Wiseman, Platner, Turner, Desault, Hill, J. Bell, Abernethy, Hennen, and Thomson, where patients have recovered without the operation of trepan, especially among young people. As long, therefore, as there are no urgent symptoms of compressed brain, so long there can be no necessity for trephining, but merely strict and active antiphlogistic treatment, and by which mode of delay, the aggravation attendant on the operation is avoided.—"Si nulla mala indicia sunt, modioli usus supervacuus est." "It is remarked, that in times of war and trouble, when men are not allowed to take care of their wounds, those who are least cared for are soonest cured; and a man who is forced to wrap a clout about his head and ride for his life, is safer than one who is chambered up, dieted, and dressed, and perhaps trepanned by the surgeon." Cases have occurred where the trephine was about to be applied to a depressed bone, when the patient has awoke from the stun of the blow. The depression frequently extends only to the inner table of the skull. There are some exceptions, however, to this general rule of the non-employment of the trephine; thus, for example, when the bone is injured with a sharp-pointed instrument, as a mason's chisel or a spike of an iron railing, the spiculæ project in such a manner inwards upon the brain, as to require a large crown of a trephine to encircle and remove the whole: this is termed the punctured fracture. Secondly, if the bone be so indented as to afford every reason to believe there are spiculæ projecting inwards, it is also proper. Thirdly, the application of the trephine is also considered by some indispensable in compound fracture, and in the camerated fracture of the ancients, but unless spiculæ are supposed to be formed, there are no just grounds for such an operation; since the antiphlogistic treatment is sufficient. When the trephine is used in depressed bone, the centre pin of the instrument must rest on the sound portion of the cranium, while a little less than the half of the circle includes the depressed portion: previously however to its application, a tripod incision of the scalp is made, and the scalp dissected back from the pericranium, the latter of which being easily cut with the teeth of the saw, forms no impediment to its operation. Having removed a portion of the sound cranium with the trephine, the elevator is inserted beneath the depressed portion, and steadily elevated. From this it will at once appear evident, that the trephine should be applied to that portion of the sound cranium opposite to the most depressed and loose portion. Hey's saw, depicted in Fig. 19 of Plate DXV. is oftener employed to remove a sound part of the bone, so as to allow the elevator to be used, because a smaller portion can be taken away with it, and it can even be applied to the depressed portion; all spiculæ or fragments must be carefully picked away. The remaining steps of this operation have been already detailed. In some instances of depressed bone, even Hey's saw is not necessary, there being sufficient space to use the elevator. A case is related by Sir A. Cooper, of a man who remained comatose for thirteen months, in consequence of depressed bone, and who was then trephined and recovered.

When symptoms of compression of the brain are produced by extravasion of blood, there is generally an interval of sense between the receipt of the injury and the insensibility occasioned by the effusion of the blood, and commonly some degree of swelling of the scalp; but in other cases, the individual lies in a state of stupor from the first, and there is no mark or trace where the effusion has taken place, or whether he be not in a state of concussion; while in others again, only one or more symptoms of compression present themselves. Sometimes the blood-vessels of the dura mater are ruptured, at other times those of the brain; hence, the effusion of the blood may either be between the cranium and dura mater; the dura mater and arachnoid membrane; the arachnoid membrane and pia mater; in the medullary substance of the brain, or in the ventricles. The first of these is more or less circumscribed; and when it occurs at the basis of the cranium is generally fatal. When between the dura mater and arachnoid membrane, the blood is extensively diffused, so that unless the quantity be great, there is no marked degree of pressure. It is also widely extravasated when situated between the arachnoid membrane and pia mater, one of its most common seats, and does not produce much pressure, unless the quantity be considerable. When effused in the medullary substance of the ventricles, it is circumscribed, and resembles that effused in apoplexy. In some rare cases, blood has been extravasated at once in all of these places. In the treatment of this affection, when the blow has been severe, and the patient lies in a state of stupor from the beginning, we can only use the lancet, and watch the progress of the symptoms, and if these continue clearly indicating compression, apply the trephine. If the blow has not stunned the patient, bloodletting nevertheless should be had recourse to, as it may check the further effusion of blood, and prevent inflammation succeeding. If the patient recovers from the insensibility which is occasioned by the blow, and again relapses into stupor, the trephine should be instantly applied. If there be no tumefaction of the scalp to denote the seat of the injury, the instrument must be applied in the region of one of the meningeal arteries, where it imprints the anterior inferior angle of the parietal bone, being there commonly encased in a bony canal, and consequently very liable to be ruptured either from the unyielding nature of the bone, or from fracture of this delicate osseous channel. If no extravasated blood be found on the side we have trephined, there is no other alternative than the applying of the instrument to the opposite side; and even then the blood may be effused in the basis of the cranium. If no blood be found between the bone and dura mater, but the latter appears purplish, it is probable the fluid is effused between the arachnoid membrane and pia mater, and in such an event we appear justified in puncturing these membranes, in order to give exit to the blood, although it is commonly so extensively diffused, that it either proves fatal by compression, or by inducing inflammation. Cases are on record where both sides of the cranium required to be trephined, the first operation removing only one clot of extravasation, and symptoms of compression still continuing until the opposite was removed. No reliance should be placed on the condition of the bone, as inculcated by some writers; it is of no moment whether the bone be dry or bleed, for its circulation may be carried on for a time by the vessels of the diploe.

Concussion is that state of the brain which results from a fall or blow, wherein its particles are so agitated, and its minute vessels so injured, that symptoms of compression are more or less evidenced; for if the violence of the concussion produce lesion of the medullary fibres or globules, and extravasion of blood, as was observed in dissections by Sir A. Cooper, the same train of symptoms must take place in concussion as in compression. Pott, Desault, and Bichat assert, that concussion and compression are frequently evinced by the same symptoms. In the majority of cases, the patient lies comatose, but still feels when his skin is pinched; the pulse is slow and intermitting; the breathing laborious without stertor; the pupils in some degree dilated; and the extremities cold. If not attended to, he remains for some time in this state, and either falls a victim, or becomes paralytic, or is attacked with inflammation of the brain, which may be said in such a case to be beyond the power of art. Inflammation is the most frequent consequence, and there often occurs a longer or shorter interval between the state of oppression, and that of excitement, which have been divided by Mr. Abernethy into three stages, but such a division is seldom verified in nature, and has led to erroneous practice. The treatment of concussion is by active and strict antiphlogistic means from the very beginning; copious bloodletting at this early period is supported by Sir A. Cooper's dissections, and by his own scientific practice, and also by that of Pott, Boyer, J. Bell, Abernethy, and Hennen. Broomfield, B. Bell, and Allan recommend cordials. The most characteristic symptom of concussion, is that degree of sensibility even in a comatose state, and which resembles somnambulism, some extraordinary and diverting cases of which are related by Sir A. Cooper. Concussion occasionally co-exists with extravasion of blood, the former preceding the latter; and so also do compression and concussion. The symptoms set down as indicating either of these conditions of the brain, are far from being conclusive, as is candidly acknowledged by many experienced surgeons. Convulsions and paralysis are frequently consequent on these affections of the brain.

In injuries of the brain, there occasionally exist some remarkable peculiarities in the symptoms, those in the pulse are related in Latta's *Surgery* and Hennen's *Military Surgery;* those of the memory in the latter work, and in Larrey's *Memoirs of Military Surgery* and Sir A. Cooper's *Lectures;* those of the stomach and liver, by Bertrandi, in *Memoirs of the French Academy of Surgery*, vol. iii. in Pouteau's *Works*, Desault's *Works*, J. Bell's *Principles of Surgery*, Richerand's *Nosographic Chirurgicale*, Hennen's *Military Surgery*, and *Rose's Observations upon Depositions of Pus and Lymph;* but it is doubtful if these visceral sequences are not the result of confinement.—See *Edinburgh Annual Register* for 1822.

Acute inflammation of the brain generally soon ends fatally, either by general effusion between the arachnoid membrane and pia mater, and also into the ventricles; or by effusion of coagulable lympth; or by suppuration of the arachnoides and pia mater. Gangrene and blood are said by Bursarius, Riverius, J. Bell and others, to be also terminations. The first of these constitutes acute hydrocephalus, which prevails both in the child and in the adult, and originates from many causes; and when it is evident that effusion has taken place, there is no hopes of relief but by an operation, however faint that hope may be; for no medicine as yet discovered can remove the effused fluid. The operation must be performed early if at all, and ought to be repeated on any appearance of re-accumulation of the fluid. In all cases where the symptoms have crept on gradually and insidiously, the water is found effused solely in the ventricles; while, where the symptoms have been rapid, the effusion has taken place, both within the cavities and on the surface of the brain; because in the latter it produces compression more suddenly, for it is only when the whole brain is acted on by the general pressure of the fluid, that its functions are paralyzed or destroyed. Chronic hydrocephalus, from being generally congenital, and from the cavity in which the fluid is contained being invested with an epithelium, resembling coagulable lymph, there is less chance of success. In infancy the operation is performed with a small trocar and canula, which is carefully plunged into one of the lateral ventricles, at one of the lateral corners of the anterior fontanelle. After the closure of this fontanelle, especially when the bone has become ossified, a small trephine is required to remove a circular portion of the bone, before having recourse to the trocar and canula. In those cases however, where the fluid is effused between the arachnoid membrane and pia mater, and at the same time into the ventricles, the mere puncturing of the arachnoid membrane with a lancet will evacuate the fluid, in consequence of the free communication inferior or basilad to the velum interpositum Halleri. For an account of hydrocephalus, the reader is referred to the article Medicine, to *Edin. Med. and Surg. Journal*, vols. xv. and xvi; and *Medico-Chirur. Review*, vol. vii. No. 21.

Chronic Hydrocephalus occurs also between the dura mater and arachnoid membrane, as lately proved by the dissection of a patient in Guy's Hospital. The fluid sometimes appears through a foramen of the cranium from a deficiency in the bone, and forms a tumour, whose sac consists of the dura mater and integuments. This has been termed spina bifida; although spina bifida or hydro-rachitis literally applies to a disease of the spine, and consists of a malformation of the osseous canal, the spinal cord and its membranes; the bone being deficient in few or more of its spinous processes and arches, the membranes with the integuments forming a pouch, which contains either the cord itself or the nerves, together with serous effusion. The fluid only occasionally communicates with the ventricles of the brain, and is precisely analogous to congenital hydrocephalus. Children seldom live for many years under this affection, but there is on record a person who survived until twenty years of age. This disease generally occurs in the lumbar or sacral region, but has been observed also in the dorsal and cervical, and in one instance the spinous processes were deficient the whole length of the column. Sometimes there is a double cyst. In consequence of the effused fluid pressing upon the nerves, there is involuntary passage of the feces and urine, and this is instantaneously produced, together with occasional convulsions, by external pressure on the tumour; and in the worst cases paralysis of the lower extremities is present. The treatment is by puncturing the tumour with a fine needle, previously drawing upwards the skin that it may act as a valve; and whenever the water collects, removing the fluid, but never the whole quantity at once, as it is liable by producing a collapse to prove fatal. Between the intervals gentle pressure should be applied. Caustic and ligature have proved fatal. Apoplexy has been already treated of under Medicine, Vol. XIII. p. 11. The reader is also referred to Abernethy's *Surgical Works*, to J. Bell's *Principles of Surgery*, and to Dr. Armstrong's *Lectures*, for further information on this interesting disease. Paralysis or palsy has been also described under Medicine.

Besides the diseases of the brain already enumerated, there are several diseased secretions, such as calcareous depositions, scrofulous tumours and abscesses, and globular vascular tumours, some of which are evidently scirrhous, and all of which are described by Platerus, Bonetus, Baader, Anderson, J. Bell, Bateman, Yellowly, and Baillie. These tumours produce acute or obtuse pain of the head, either constant or intermitting; occasionally the pupils appear dilated with more or less strabismus; now and then convulsive or epileptic fits, commonly transitory; and not unfrequently paralysis of one or more extremities: and in the last stage, symptoms of compression. In most cases the side opposite to the tumour is affected with paralysis, according to a principle generally prevalent in effusion of blood or matter in the brain. When these tumours are situated in the region of the optic nerves, vision is impaired; when on the tuber annulare or medulla oblongata, convulsions manifest themselves. Such tumours are beyond the reach of surgery. Fungoid tumours occasionally grow from the dura mater, in consequence of the latter being injured in a general concussion of the brain, and of then healing apart from the cranium, which is absorbed by the pressure, and allows the fungus to protrude. These tumours are also generated when the cranium is rendered carious, and the dura mater separates slowly from the bone. They excite either epilepsy, or palsy, in which the bone remains firm, and forms a resistance to the tumour; and when pressed upon, pain, tremors, and convulsions are excited. Instances are detailed by Baader, Sivert, Le Grand, Chopart, Marignes, Hill, and J. Bell. These tumours when opened, immediately prove fatal, so that the patient's sufferings can only be palliated. In the Edin. Medico-Chir. Trans. vol. iii, an interesting case is described by Dr. Stewart, Physician to the Forces. These tumours seemed to originate in the diploe. The air of particular countries and hospitals has been considered to be more prejudicial to injuries of the head than other wounds, by Lusitani, Phioravanti, Donatus, Saviard, La Motte, Petit and Desault; but this is evidently to be ascribed to the importance of the organ injured. The rapid putrefaction of those who die of such affections is also taken notice of, which is to be accounted for, by the centre of the nervous energy being injured in its organization.

The ear is subject to many diseases which are commonly left to the aurist. The auricle is affected in early life particularly with a herpetic ulceration, which sometimes spreads over the scalp, producing tinea capitis, and is to be treated in the same manner, preceding it, however, with anodyne fomentations and poultices, until all inflammatory action is subdued. The cerumen of the auditory tube is sometimes too copious, and slightly impairs the hearing, and is readily checked with the same astringent lotions and ointments, as mentioned under tinea capitis, together with a blister behind the auricle. When the secretion of the cerumen is scanty, deafness is occasionally the result, and is to be remedied by electricity gently administered, and an ointment of iodine applied at bed time, and washed away in the morning with soap and water. Children often insert pease and other foreign bodies into the auditory tube, the removal of which, although tedious, may be accomplished by a common probe, having the eyed-end bent. When cotton or wool has been inserted in the tube, and allowed to remain surrounded with cerumen sometimes for years, deafness is gradually produced, in which case the cerumen becomes exceedingly hard, and should be softened with oil of olives for six or eight nights, before attempting to remove it by syringing the ear with warm water and soap. Various insects sometimes get into the tube, and produce a terrific noise resembling thunder, and occasionally convulsions. They are easily killed by dropping oil of olives into the ear, or a decoction of tobacco, and afterwards, if small, syringed out, and if large, removed with the forceps or probe. These various objects are easily discovered by means of Buchanan, Le Roy or Segala's speculum, delineated in Fig. 25, Plate DXVI., or simply by placing the ear affected in the rays of the sun, and taking hold of the auricle with the thumb and forefinger, and gently raising or elongating it.

Polypus not unfrequently grows from either the sides of the tube or the membrane of the tympanum, impairing the hearing, and sometimes destroying the membrane, the tympanic cavity, and extending its irritation to the dura mater and proving fatal. It generally produces a copious discharge of fœtid matter from the tube; and is to be treated as Polypus in the nose, with fully more caution, as they are liable to excite inflammation and suppuration of the dura mater and prove fatal. Children are seldom born with a septum shutting up the auditory tube, but when such occurs, it ought first to be punctured with a very small trocar, for it might be the membrana tympani; and if found to be an adventitious septum, it ought to be entirely removed with forceps and knife or scissors. The membrana tympani is sometimes so relaxed that it cannot receive the aerial impulsions, and hence more or less deafness results; and is to be treated with electricity and the iodine ointment. It is sometimes ruptured from blowing the nose too forcibly; and occasionally thickened after measles and other acute diseases, and likewise in syphilis: when it is consequent on measles, &c. electricity and iodine ointment are applied to the tube, with blisters or moxas around the root of the auricle. When it occurs in the syphilitic constitution, these are to be combined with mercury, &c. The threads of the facial nerve supplying the ear and the chorda tympani are subject to neuralgia, which is here termed otalgia, and is to be treated in the same way. If dependent on a carious tooth, this should be extracted, and a decoction of tobacco dropped into the tube. The Eustachian tube becomes obstructed from many causes, some of which are mentioned under diseases of the nose; it is easily distinguished by making the patient shut his mouth and compress his nostrils, while he attempts to breathe through the latter with a gentle force, when, if the tube be pervious, the air will rush along it, and cause a crackling sound of the membrana tympani, whereas, if the tube be shut up, no sound is heard; also, by putting a watch between his teeth, when its sound will be heard if the auditory nerve be healthy. It is extremely difficult to insert bougies along the nares into the tube to dilate it, unless by means of the speculum, Fig. 25, Plate DXVI.; and therefore the membrana tympani should be punctured with the trocar by inserting it sheathed in the canula until the latter meets with resistance from the membrane, which is known by the yielding and springing vibration felt, and then the trocar is to be pushed along the canula, and the membrane punctured. In this little operation, the rays of the sun should be directed along the tube, and the auricle held as in inspecting the ear. When the obstruction is recent, it is most probably from mucus, and may then be removed by injections of warm water. Inflammation of the internal organ named otitis has been already described in MEDICINE. Otorrhœa is a discharge of fetid ichorous matter from the mucous membrane investing the tympanum, and occasionally even from the vestibule, cochlea, and semicircular canals, the bone being occasionally carious. Sometimes it begins in the ear itself, on other occasions within the cranium, and succeeds various acute febrile affections, particularly in scrofulous constitutions. Air rushes out from the pharynx at the ear, and water injected by the tube flows into the pharynx; and the ossicula auditus, especially the malleus and incus, are generally discharged. This affection should be treated as ophthalmia. An abscess sometimes takes place in the mastoid cells in children, the communication with the tympanic cavity being shut up with coagulable lymph, in which case the application of a small trephine is necessary, otherwise the disease proves fatal. The labyrinth is subject to many affections, the greater number of which are beyond our compre hension, partly from our ignorance of the physiology of this most interesting and most important organ, and partly from the difficulties encountered in examining morbid cases, in consequence of the prejudices of the public. There are diseases of the auditory nerve, of the *fenestra ovalis et rotunda*, and of the secretion of the labyrinth. For further information on this interesting branch of pathology, the reader may consult Itard, *Traité des maladies des oreilles.* Saunders *On the Ear.* Buchanan *On the Ear*, and M'Crae's interesting inaugural dissertation *De Morbis Auris*, 1828.

In consequence of the division of Medicine and Surgery into Physicians, Surgeons, Accoucheurs, Oculists, Aurists, Dentists, &c., the diseases of the eye have multiplied to no less a number than one hundred and eighteen; a catalogue at once frivolous and arbitrary.

Ophthalmia, or inflammation of the eye, is most absurdly subdivided according to the part affected, thus there are ophthalmia conjunctiva palpebrarum, ophthalmia conjunctiva oculi, ophthalmia conjunctiva corneæ, and ophthalmia sclerotica. There is also idiopathic, symptomatic, erysipelatous, mucous, purulent, catarrhal, orbital, and chronic ophthalmia.

In acute inflammation of the eye, there are pain, heat, redness, and swelling, with the feeling of sandy particles between the upper eye-lid and the ball of the eye, and an increased secretion of tears and mucus; which symptoms vary according to the severity of the injury, and the extent of the inflammation. As the disease advances, it extends to the brain, and the whole constitution, producing more or less phrenitis and inflammatory fever. The sensation of sand is caused by the blood-vessels of the eye-ball becoming turgid with blood, and being felt as a neutral body between the globe of the eye and the eye-lid. The eye, when thus affected, has its blood-vessels enlarged and increased, those which formerly carried serum, now conducting coloured blood, while the ciliary glands appear turgid and secrete yellow mucus resembling pus. The treatment depends on the violence of the inflammation: if the brain or constitution be not affected, leeches, warm anodyne applications, cathartics, low diet, rest and confinement in a darkened chamber will suffice: but if the brain or constitution be involved, general blood-letting from the temporal artery, external jugular vein, or one of the veins of the arm, will be required. The turgid vessels of the eye-ball and eye-lids ought only to be scarified when the affection is tardy, or these blood-vessels threaten to shoot over the cornea. The rubbing in gently of the extract of belladonna on the outer surface of the eye-lids and contiguity is of benefit. Whenever the sensation of sand leaves the eye, the warm applications are to be laid aside, and pure cold water used in their stead, bathing the eye whenever it feels weak and tender; at the end of twenty-four hours, rose-water is to be substituted, and after a few hours perseverance, as much sulphate of zinc is to be added as to produce the feeling of heat in the eye. This solution is to be progressively and cautiously strengthened, and to be dropped into the eye whenever it feels feeble. Laudanum may be early added to it, and afterwards sulphuric ether. As soon as the sulphate of zinc can be employed, the margins of the eye-lids should be gently anointed at bed time with an ointment of the red oxide of mercury, in the proportion of three grains to the two drachms of lard. After blood-letting has been performed, blisters to the temples and nape of the neck will be found advantageous. There are other local astringents besides those mentioned. If the eye-ball feels very tense, it will be advantageous to evacuate the aqueous humour with a couching needle. See Fig. 22 of Plate DXV. The causes of ophthalmia are exceedingly various; when it arises from sand, lime, pepper, snuff, insects, &c., they should be washed away with warm water and a syringe; when from a piece of a quill, iron, steel, gunpowder, small leaden shot, the couching needle, or cataract knife, depicted in Fig. 20 of Plate DXV., the forceps and camel's hair brush are the best to remove them. When ophthalmia becomes chronic, which is best distinguished by its duration, it ought to be treated with the same astringent applications rendered gradually stronger, together with mercurial ointment and opium to the eye-brow, and blisters, moxas, and setons. For further information on ophthalmia, the reader is referred to the article MEDICINE.

Iritis or acute inflammation chiefly of the iris, although it affects at once the whole choroid coat, and rapidly extends to the other structures of the eye, is consequent either on an injury, or occurs in syphilis, gout or chronic rheumatism, and frequently after operations on the eye. The surface of the eye, or tunica conjunctiva, is slightly inflamed, the iris appears swollen, changes its colour, when naturally black or brown to red, and when grey or blue to green, and the pupillary is darker than the ciliary margin, with some degree of deformity, not being so distinct and sharp, and gradually becoming more and more contracted. The inflammatory action extends most rapidly to the capsule of the lens, to which the iris is liable to adhere, and a deposition of lymph takes place early in the texture of the iris. There is a dull heavy pain of the eye, with intolerance of light, violent headach, and symptomatic fever. This affection requires very active antiphlogistic treatment; and after the first bleeding, mercury ought to be administered so as to prevent the deposition of lymph, or to excite its absorption; and in order to prevent the adhesion between the iris and capsule of the lens, the extract of belladonna ought to be employed, also mercurial ointment, with opium. Coagulable lymph is not unfrequently effused into the posterior chamber of the aqueous humour, especially in the iritis consequent on syphilis, and forms a delicate semitransparent web, which shuts up the pupil. Closure of the pupil also occurs from adhesion of the iris to the cornea, and is that in which an artificial pupil succeeds best. This operation, however, should never be attempted if the patient can see with the other eye, or when there is any complication of disease, and not until all inflammatory tendency has ceased for some time. In the majority of cases, there is more or less opacity of the cornea, so that the best point of the iris for making a pupil depends on the part where the cornea is transparent; it is therefore better to remove the opacity in the first instance. Various modes have been recommended for making an artificial pupil, from Chesselden downwards, and the most simple is that supported by Janin, Maunoir, Guerin, Scarpa, Richter and Beer, which consists either in making a puncture of the cornea with Daviel's scissors, as represented in Fig. 11 of Plate DXVI. at the upper part, and then cutting the iris perpendicularly near the inner or nasal canthus, or in making an incision of the cornea, first with the cataract knife, and next using the scissors.

Hydrophthalmia is dropsy of the eye, consequent on violent acute ophthalmia, and in this disease the eye is swollen, with protusion of the cornea, which is tolerably clear, although the aqueous humour is turbid. The sclerotic coat around the cornea is of a blue colour, the iris dull and dark, the pupil neither contracted nor dilated, and the vitreous humour much increased in quantity. In the beginning of the disease, the patient sees objects at a greater distance than formerly, or is far-sighted, but this soon changes to weakness of vision, the eye becomes horribly disfigured, its textures are disorganized, the bones of the orbit rendered carious, and the patient is soon cut off. By some, it is stated that the tunics burst, while by others this is denied. In the commencement, the cornea should be punctured, or an issue or a seton established, as recommended for staphyloma; and if these fail, the cornea ought to be removed, as described under that disease. Hypopium is an effusion of coagulable lymph and purulent matter in the posterior, and afterwards into the anterior chamber of the aqueous humour, consequent on acute ophthalmia, and is to be treated by active antiphlogistic means, and puncturing the cornea, also using astringent and stimulating ointments, with an alterative course of mercury. If not cured, adhesion of the iris to the capsule of the lens, and an opacity of the lens, together with ulcer of the cornea, are liable to follow.

Opacity of the cornea, named also albugo, leucoma, nebula, and speck, is one of the consequences of ophthalmia, whether acute or chronic. Nebula is said to be the result of chronic ophthalmy, and to consist of an effusion of milky serum in the tunica conjunctiva corneæ, with thickening of this coat and varicose veins; albugo, to be an effusion of coagulable lymph between the laminæ of the cornea, consequent on acute ophthalmy, and to have first a milky and then a pearly appearance; and leucoma to be also an effusion of lymph, but to occupy the whole extent of the cornea, and to arise either from violent acute ophthalmy, or ulceration of the cornea, or a wound of this tunic; but these opacities indiscriminately arise from chronic as well as acute ophthalmia, and being evidently the same disease, require therefore the same line of treatment, which consists in applying daily, or every second day, the dry nitrate of silver for an instant to the opacity, and bathing the eye for a few minutes afterwards with warm water or oil. In children it may be removed by blowing into the eye a finely levigated powder of equal parts of calomel and white sugar. In acute inflammation of the eye, a pustule occasionally appears on the cornea which requires to be freely opened; otherwise the depression or pouch is filled with lymph, and forms an opacity or leucoma. This pustule sometimes appears larger and more formidable, and is then termed an abscess, which should be treated in the same way. When the abscess bursts, it becomes an ulcer which is characterized by high ragged edges, by the base being of an ash-colour, and the discharge acrid serum. An ulcer is also consequent on wounds from sharp-pointed instruments, glass and lime. The symptoms are the same, as in acute or chronic ophthalmy according to its duration; and the best diagnostic of an ulcer is the pain produced on looking at the light, for on general examination it very much resembles an opacity of the cornea. A chronic interstitial ulcer is described by some oculists. If an ulcer of the cornea be neglected, it either spreads superficially and destroys the transparency of this tunic, or penetrates deeply to the anterior chamber of the aqueous humour, producing a fistulous aperture, where prolapsus of the iris may take place, and even protrusion of the crystaline and vitreous humours. A fungous excrescence sometimes protrudes, resembling a pterygium. As long as the pain is severe, and there is acute inflammation, it should be treated as the irritable ulcer of other parts; and whenever these are subdued, by the application of the nitrate of silver every two or three days; and when granulations are visible, by astringent collyria. Puncturing the cornea to evacuate the aqueous humour and thus relieve the tension and pain will be found beneficial, and prevent prolapsus iridis taking place. If a fungus shoots forth, it ought to be excised with the knife or scissors, and the nitrate of copper or silver afterwards applied.

When the cornea ulcerates, and the aqueous humour escapes, the support of the iris is removed, and the latter protrudes, forming prolapsus iridis, named also staphyloma and procidentia iridis. This also ensues occasionally after the operation of extraction of the lens, likewise when the cornea is ruptured by a contusion, especially from glass, and in evacuating the matter in hypopium, and even sometimes from violent vomiting. The iris appears like a small dark brown or grey tumour, surrounded by an opaque circle of the cornea, with an oval-shaped pupil, and more or less inflammation of the conjunctiva. On some occasions, there is more than one protrusion, simply because there is more than one aperture. The symptoms are pain like a pin pricking the eye, an oppressive sensation of tightness over the eye-ball consequent on the strangulation of the iris, a burning effusion of tears and intolerance of light. If the prolapsus be recent, an attempt should be made to reduce it with a probe, but if that fails, as it is very difficult, it may be removed with the knife, scissors, or nitrate of copper or silver, taking care not to continue the application of the escharotic too long. Whenever the wound heals, the pupil tends to reoccupy its former situation, although the adhesion remains. The wound is recommended by some oculists to be enlarged, which is improper; by others, the iris to be stimulated to retire into the eye by exposing the eye to a vivid light, a practice still more improper. Besides the iris being protruded, the investing layer of the cornea is occasionally forced out filled with the aqueous humour in the form of a transparent vesicle, and termed by Janin prolapsus of this tunic, in which formation of this disease he is joined by Pellier, Guerin, Descemet, Demours and Veitch; this is considered by Scarpa to be the hyloid membrane of the vitreous humour; while Bëer and Travers conceive it to be the innermost lamella of the cornea, the former naming it ceratocele. We are disposed to consider Janin in the right. The symptoms and treatment of this protrusion are the same as in prolapsus iridis. The choroid coat has also been protruded through the sclerotic near its junction with the cornea, in consequence of violent ophthalmia producing an abscess at that point. This is to be treated in the same manner as the last.

Staphyloma (from σταφυλη, *a grape*) consists of an opacity with distention of the cornea, according to Scarpa; while according to Richter, there must be also an adhesion of the iris to the cornea, but it may certainly be both. The eye has a disgusting appearance, from the variegated or mottled look of the cornea, which is alternately of a white, bottle-blue, or purple colour. Sometimes only the one half of the cornea is affected, which is commonly the lower; sometimes the cornea forms one uniform convex projection, while at others there are two or more, giving it a nodulated appearance. The distended condition follows a superabundant secretion of the aqueous humour, for in many cases the individual has indistinct vision with remarkable projection. Staphyloma is the result of acute, especially the purulent form of ophthalmia, and occurs frequently in children after small-pox From the projection of the eye-ball, it is exposed to the sun, air, and to particles of dust producing friction between it and the eye-lids, and rendering it a most distressing complaint; and it not unfrequently ends in ulceration of the cornea. This affection, if vision be totally gone, is to be treated by piercing the projected part of the cornea with a tenaculum, pulling the eye-ball gently forwards from the eye-lids, which ought to be kept out of the way by an assistant, and then cutting away the whole projection with a scalpel at once. The eye-lids are then to be gently closed, and the eye bathed with hot water for the remainder of the day, and afterwards to be treated with mild collyria. On the second or third day, the wound is filled with coagulable lymph, which gradually cicatrizes with an opaque horny texture, not unlike the cornea. Some recommend the establishment of an ulcer at the lower margin of the cornea; while others the inserting of a seton of fine thread, but unless the adhesive inflammation accompanies the ulcerative, it fails.

Cataract, (from καταρασσω, *to confound*, is either an opacity of the crystaline lens, its capsule, or the fluid between these, or a combination of them all. The varieties of this disease, according to ophthalmologists, are truly ludicrous, and would form a rhyme for Caleb Quotam. They may, with every propriety, be reduced from upwards of fifty to four. The capsular, the lenticular, and the milky. with a combination of these, and it is even very difficult to discriminate between these four in the living body When examining the diseased eye, the sound one should be closed or shut up, in order to prevent the motions of the one influencing the other. The capsular cataract presents a general white surface behind the pupil, producing nearly total blindness, with dilated pupil, which is not affected by any light; and when belladonna is rubbed on the eye lids, no ring is seen around this white spot. This species is generally consequent on local causes. The lenticular begins in the centre of the lens, producing opacity behind the pupil, with dilatation, so that although vision is no doubt impaired, yet the patient can see in an obscure light, as the twilight, in consequence of the rays being admitted around the lens; and there is almost always a clear deep ring around, particularly if the pupil be dilated with belladonna. This species commonly arises from constitutional causes, rendering the disease idiopathic. The milky variety, termed also cataracta morgagniana, begins in the liquor morgagni, and involves the lens, which degenerates into a thin milky fluid; it also generally affects the capsule, so as to form a combination of these three textures. Cataract is sometimes complicated with adhesion of the iris, obliteration of the posterior chamber of the aqueous humour, the latter of which is termed false or spurious. This disease is either idiopathic or local, is very often hereditary, and also congenital; the hereditary disposition being very extensive, frequently affecting a whole family. In the constitutional species, the individual begins to complain of weakness of sight, that he cannot see distant objects, has a mistiness or cloudiness over his eyes, and that when he turns his back to the light, or when the sun begins to set, he sees more distinctly; and he also occasionally sees more distinctly on the one side of the axis of vision than on the other. A candle appears to him to have a halo around it, and as he recedes from it, the halo becomes broader and the flame more indistinct. These defects gradually increase until he can only distinguish between light and darkness, and then the opacity may be perceived behind the pupil, having either a gray, silvery, dead white, yellow, brown, or dirty black appearance. In some rare cases, the opacity begins with two or three white spots. Local or accidental cataract is consequent on inflammation from wounds, and is sometimes so gentle and insidious, that the patient has not been conscious of its formation. With the exception of the congenital, we never succeed in curing cataract but by an operation, and before it is performed, several circumstances are to be attended to. We must distinguish between this disease and amaurosis, and be careful that the two affections are not co-existent; also between cataract and glaucoma, and there must be no inflammatory tendency, the eye ought to be free from all other disease, and the patient to be in a healthy state. A number of other points are mentioned by ophthalmologists, which do not merit attention. The inflammatory tendency is characterized by flashes of light, fiery sparks, pain in the eye, orbit, or forehead. When both eyes are effected, the one should be operated on before the other.

There are various operations for this disease, as couching, depression, displacement, and extraction. Under the three first, there are operations posterior and anterior to the iris; under operations posterior to the iris, there are simple depression, the depression of Scarpa, and the reclination of Willberg and Beer. Under operations anterior to the iris, there are the reclination of Langenbeck and keratonyxis. Before any of these operations is performed, the patient should take a brisk cathartic the preceding day, and any other course of preparation, as recommended by some, is unnecessary. An hour or so before operating, the extract of belladonna should be rubbed on the eye-lids to dilate the pupil, when the operation of couching is performed. The patient should sit on a low chair before a clear light, with an assistant behind, who is to raise with his fingers the upper eye-lid, while the operator depresses the lower; the surgeon then inserts Scarpa's needle, previously moistened with the tears of the patient, about a line and a half from the cornea, and half a line below its horizontal diameter, at the outer canthus of the eye, directing the needle towards its centre; the hand of the operator resting on the patient's cheek. The needle is to be seen anterior to the capsule of the lens, with the one flat surface upwards, and the other downwards, and the lens is then to be depressed to the bottom of the vitreous humour, keeping the instrument above the lens for a few seconds. The motions which are described by opthalmologists, to be performed in this simple process of depression, resemble the broad sword exercise. If the lens does not rise again, the needle is to be cautiously withdrawn; but if it ascends, the depression is to be repeated. The operation of reclination of Wilberg is almost the same. Langenbeck performs reclination through the cornea anterior to the iris, with a curved needle, the convexity of the instrument being towards the lens. Keratonyxis consists in entering a spear-pointed needle through the cornea, at its inferior margin, lacerating the capsule of the lens laterally, and either merely making a small aperture in the texture of the lens, or by breaking it up, and endeavouring to bring it into the anterior chamber of the aqueous humour, where it is ultimately dissolved and absorbed by its agency. Care must be taken to prevent the escape of the aqueous humour. This operation is the simplest and safest which can be performed for cataract, whether capsular, milky, or lenticular. It is advocated by Conradi, Bëer, Saunders, Buckthorn, Langenbeck, and Walther, with a slight variation in some trifling points.

Extraction, the most radical cure for hard or lenticular cataract, is probably the most difficult to perform. The patient should lie on a firm table, and an assistant hold up the upper eye-lid, when the operator, with a cataract-knife, (Fig. 20, Plate DXV.) makes an incision of the lower half of the cornea, entering the instrument at the outer canthus, about a line from the sclerotic coat, and nearly the same distance above the horizontal plane, pushing the knife at once across the cornea, and transfixing the other side, as delineated in Fig. 5 of Plate DXVII., and then cutting downwards and outwards, care being taken not to wound the iris. If the operator cannot force the point of the knife through the opposite aspect of the cornea at once, before the aqueous humour escapes, he should gently press the cornea in front of the knife, which causes the iris to retract, and then proceed with the knife; or he may withdraw the knife, and complete the incision with Daviel's scissors, which are to be used to enlarge the incision if too limited. After the incision of the cornea, great care is required to employ no degree of pressure, otherwise the vitreous humour will protrude; the capsule needle or cataract lance is then cautiously inserted onwards to the cataract, and the capsule lacerated by crucial incisions, the operator previously seeing the pupil distinctly, which if not fully dilated, a curtain should be interposed between the patient and the light. The lens generally follows this capsule needle, but if not, the most gentle motion of the eye upwards, together with very delicate pressure on the lower eye-lid, discharges it; but if this does not take place, Daviel's scoop should be inserted between the cornea and the iris, and the lens assisted by its pressure. The operator should carefully investigate if the section of the cornea be large enough, and the capsule of the lens sufficiently lacerated. All fragments of lens should be carefully removed with the scoop, the patient put to bed, the eyes covered with a handkerchief, and warm applications, and otherwise treated antiphlogistically, according to the state of the inflammation. When the right eye is the seat of the cataract, the section of the cornea should be upwards. Extraction is recommended in hard cataract, keratonyxis for soft and capsular cataract. Capsular cataract frequently follows extraction, and then keratonyxis is requisite. There are a number of circumstances mentioned by authors, interdicting extraction, which appear frivolous. Congenital cataract is almost always the capsular, and should be removed by keratonyxis, when the child is six months old.

Glaucoma, (from γλαυκος, *bluish green*), consists, first, in an alteration of the texture of the vitreous humour and its membrane, ultimately involving the retina, choroid coat, and lens; the vessels of the choroid being varicose. The eye has an unhealthy appearance, and feels firm and hard, the cornea is turbid, the sclerotic of a bluish or yellow tinge, with tortuous varicose vessels piercing this tunic at a distance from the cornea, leaving the latter surrounded with a white circle; the iris, if naturally blue, becomes gray, and if black, a dirty brown; the pupil is dilated, irregularly angular or oval, and immoveably fixed as it were to one canthus. The individual cannot distinguish light from darkness. As the disease advances, the green colour increases; the lens swells and presses the iris forwards into the anterior chamber of the aqueous humour, when it is termed glaucomatous cataract. The treatment consists in local blood-letting, blisters applied to the temples, moxas, issues and setons to the nape of the neck, laxatives, mild diet, and the avoiding of all exciting causes.

Amaurosis, or gutta serena (from αμαυροω, *to obscure*), is generally consequent on a diseased affection of the retina and optic nerve, since the function or structure is deranged. The patient sees in the light gnats, or flies, or threads or spots flying before his eyes; while in the dark he perceives fiery sparks, or balls, and flashes of blue, yellow, or red; and often sees double and squints. The flame of a candle appears to change from white to yellow, red or green; the halo also appears of these colours; at last total blindness ensues. When the eye is examined, it is either clear or cloudy, the cloudiness being deep in the eye, the bottom of which is of a pale greenish colour resembling horn. The pupil is very variable, commonly irregular, angular and fixed. This disease is sometimes slow, at other times rapid, and is even congenital, being more hereditary than cataract; and its causes are exceedingly various, from which it is either temporary or permanent, depending either on a deranged function of the eye itself or the brain, or some more distant organ, or even on an organic affection of them all. When it originates from diseased function it is sometimes capable of being cured, but when from diseased structure incurable; and none of the diseases of the eye so completely baffles the skill of the surgeon. When diseased function is the cause, it is generally from pressure of the blood on the internal carotid or its branches, particularly the opthalmic artery on the optic nerve; also from the arteries distributed on the choroid coat when varicose pressing on the retina. In these cases, blood-letting, blisters, moxas and issues to the nape of the neck, pediluvium, shower-bath, powerful cathartics, and low diet occasionally cure it. When suppressed discharges are the cause, they require to be restored, or others to be substituted; when it arises from over-excitement, it is generally easily cured, and it is a peculiar circumstance in this case that the patient can see while under the influence of a glass of wine. When narcotics, it is curable; emetics are recommended, but they should never be administered, as vomiting is a common cause of the disease, and as calomel with other cathartics removes the diseased secretion of the stomach, and more effectually prevent regurgitation of the bile. When hydrocephalus, tumours in the course of the optic nerve, exostosis at the basis of the cranium, thickening of the retina, shrinking or atrophy of the optic nerve cause the disease, the case is hopeless. It is often very difficult to ascertain from what this disease originates. In northern and tropical climates, from the glare of the sun or snow, a variety of amaurosis occurs, which, if it produces blindness during the day, is named Nyctalopia; if during the night, Hemeralopia. A third variety exists, in which the individual is blind all day until a certain hour, when he sees distinctly, or he sees and is blind every alternate day, or is only blind one day in the week, fortnight, or month. These varieties are treated by purgatives, by removal from the effulgence of light, blisters to the temples, moxas to the nape of the neck, electricity, and nourishing diet with tonics.

Cancer of the eye begins either in the lacrymal gland, the conjunctiva, or the eye-ball itself, attacks the constitution after the meridian of life, and is characterized by acute stinging pains like the pricking of needles or lancets, the eye presenting an irregular nodulated tumefied appearance, the cornea becoming opaque, varicose blood-vessels forming on the conjunctiva, which become ultimately like flesh, and even the whole eye resembles firm flesh. When the conjunctiva is first affected, it is a common ulcerated fungus, hard and cartilaginous, attended with darting lancinating pains, exquisite sensibility, icorous discharge, and varicose enlargement of the blood-vessels, and ultimately involves the eye. If confined to the conjunctiva, we may then consider whether it ought to be removed together with the eye-ball, but if the eye-ball itself is affected, the whole ought to be extirpated. The eye-ball is to be transfixed with a curved needle, armed with a broad ligature, and if the eye-lids can be preserved, an incision is to be made between them at the outer canthus, to enable the operator to use more freedom; the conjunctiva at its angle of reflection between the eye-lids and eye-ball is then to be divided completely round: next the insertions of the superior and inferior oblique muscles; the knife is then carried close around the bone, and deep into the orbit, pulling gently at the same time the ligature, and lastly dividing the origins of the recti muscles, and the optic and other nerves. Great care should be taken to remove every portion of the disease, and if there be much bleeding, a piece of dry sponge should be inserted, or the actual cautery applied; but if not, the orbit ought to be gently filled with lint, with a small compress over the eye-lids, and a bandage around all; the patient put to bed, and an opiate administered. Inflammation may be apprehended, and the patient ought to be treated accordingly.

Fungous hæmatodes also attacks the eye, commencing in the retina and optic nerve, the vessels of which secrete the peculiar medullary matter that fills up the whole cavity of the eye-ball, presenting an irregular nodulated appearance, with a muddy cornea, and a dark livid coloured conjunctiva. At first, the cornea is so transparent as to resemble a piece of polished steel, or a concave silver plate, and the bottom of the eye is greenish, or of a dark amber colour, the pupil being dilated and immoveable. As the tumour advances to the iris, it can be seen to be a solid body of a yellow or brown colour and an irregular shape, with arteries ramified upon it. The aqueous, crystalline and vitreous humours are absorbed, together with the retina and choroid coats; the optic nerve becomes thickened, of a brownish colour, and divided by the tumour into threads. The nerve is sometimes involved even backwards to the thalamus and anterior lobe of the brain. The cornea or sclerotic coat ulcerates, and a fungus protrudes of an irregular, red colour, covered with coagulated blood, bleeding on the slightest touch, and discharging a fetid matter. The lymphatic glands in the region of the parotid and submaxillary glands become affected. On rare occasions, the disease begins in the cellular tissue, connecting the conjunctiva to the cornea. This affection also requires extirpation of the eye, but unless the operation be early performed, it rarely succeeds. It attacks chiefly children under twelve years of age.

Cancer of the lacrymal gland is a very rare disease, and is characterized by lancinating pains in the region of the organ, which from its irregular hardness and enlargement, presses the eye-ball downwards and outwards, which cannot be turned towards the external canthus without producing violent pain. This also requires removal by the knife, although it is objected to by Beer and others. An incision should be made over the tumour parallel with the superciliary ridge through the integuments, orbicularis palpebrarum, and ligament, which descends from the frontal bone until the tumour is exposed, which is then to be insulated from the bone and muscles of the eye, and removed. If hemorrhage follows, it must be stemmed with dry sponge and pressure. The lacrymal gland is occasionally subject to inflammation and suppuration, and an encysted watery vesicle, for the encysted lacrymal swelling, and the watery vesicle of the lacrymal gland are the same disease. During inflammation, there is a suspension of the secretion of the tears. The encysted swelling arises from the obstruction of the ducts of the gland, for the tears collect and form a pouch, which should be punctured, and a seton inserted from the conjunctiva to the skin at the external canthus, or a portion of the pouch removed with scissors, in order to obliterate the sac.

Tumours of the eye-lids are very common, from a simple stye to a cancerous watery excrescence. Hordeolum or stye is a small phlegmon generally on the margin of the lower eye-lid, and is commonly one of the ciliary glands, which advances slowly to suppuration and bursts; and it occurs most frequently in the scrofulous constitution, and may be treated as a common phlegmon.

If hordeolum does not suppurate, it is liable to degenerate into a hard tumour, named chalazion, grando, lythiasis, tophus, porosis, &c. which are sometimes small fleshy tumours containing calcareous matter. These require to be extirpated, for if allowed to remain, they often produce a malignant ulceration. Other small tumours of a fatty or chalky nature, or hydated vesicles, termed phlyctenulæ, occur on the eye lids, which require to be lanced, and their contents squeezed out. Warty excrescences should be excised. Encysted tumours are very prevalent on the eye-lids, occurring sometimes between the tarsus and skin, on other occasions between the tarsus and conjunctiva, in which latter situation they ought to be extirpated, if possible, from the inside of the eye-lid, by making an incision parallel with its margin; and after its removal, the wound should be anointed with oil of olives to prevent adhesion. As inflammation is liable to follow this operation, the patient must remain in a darkened room on low diet.

Encanthis, (from εν, κανθος, *the angle of the eye*,) is an enlargement of the caruncula lacrymalis, which ultimately involves the plica seminularis, and when inveterate extends along the eye-lids and surface of the eye-ball to the cornea, and even the whole eye, it being then purely cancerous. It ought therefore to be excised as early as possible; for, in its advanced stage, the whole eye may require to be extirpated.

Pterygium (from πτερυξ, *a wing*) is a triangular object or tumour situated on the conjunctiva, generally at the inner canthus of the eye, with its base towards the caruncula and apex towards the cornea.

There are two species of this, the membranous and the fleshy pterygium, both of which require to be removed with the forceps and knife or scissors, since they are liable to degenerate into a malignant or cancerous nature, although they often remain dormant for years. When they become cancerous, the whole eye should be extirpated. A small deposition of matter sometimes takes place near the edge of the cornea, which should be removed. Small oval substances, of a dirty yellow colour, also form in advanced life, in this place, which may be left alone so long as they remain inert. Fleshy and cartilaginous tumours are not unfrequently formed beneath the conjunctiva, and require extirpation. A small pale red, hard and itching tumour of the size of a pin's head is found on the lower eye-lid, near the plica semilunaris, occurring in chlorotic young women, and likewise requires removal with the knife.

Lippitudo, or blear-eyedness, is a diseased secretion of the ciliary glands and conjunctiva palpeblarum, the eye-lids are red and excoriated, are glued firmly during sleep, and vision is in some degree weakened or impaired. The treatment consists of warm anodyne applications in the first instance, and afterwards of cold astringents and stimulant ointments as mentioned under ophthalmia. The preceding affection often gives rise to diseases of the lacrymal passages; and on everting the eyelids, they present a villous granulated appearance, with swollen ulcerated ciliary glands; and in scrofulous patients the lacrymal sac is frequently inflamed from this source. In which case, there is a circumscribed hard tumour of the shape of a bean, in the situation of the sac, attended with lancinating pains when touched, and soon having a red external appearance, which is more or less erysipelatous. The lacrymal puncta or papillæ are shrunk and invisible; the tears flow over the cheeks, and the affected nostril is at first moist, but soon becomes dry. There is more or less headach and even symptomatic fever. The inflammation ultimately extends to the conjunctiva of the eye-lids, the caruncula lacrymalis and plina semilunaris, producing a copious secretion of tears, mucus, and purulent matter; coagulable lymph is effused into the nasal duct, the sac enlarges, the skin becomes of a deep red with a white point in the centre, and ultimately bursts, forming a fistulous opening. The moment that the sac tumefies, and the tears are shed over the cheek, that instant it should be freely lanced, and afterwards treated on the common principles laid down under inflammation and suppuration; attention being paid at the same time to the ciliary glands and conjunctiva, as recommended under ophthalmia; and likewise, to the nasal duct, which is more or less obstructed. At first a simple gum bougie should be inserted into the duct, and worn as long as it produces no painful feeling or inflammation. This should be repeated either daily or every second day, first washing out the sac and duct with warm water, and afterwards with a solution of the sulphate of zinc in rose water, gradually increasing its strength. The bougie is to be progressively enlarged, to the size of a large crow quill, and anointed with a weak ointment of the red oxide of mercury, which ought also to be gradually augmented. If the lacrymal sac does not advance to ulceration and rupture, a discharge of puriform mucus takes place, named blenorrhœa, in which affection the tears flow over the cheek. This requires to be treated as the preceding, otherwise it gives rise to repeated attacks of erysipelatous inflammation of the integuments over the sac, which ultimately induces closure of the nasal duct, or a communication with the sac named spurious fistula of the sac; or ulceration of the sac and integuments forming true fistula lacrymalis, in which latter case obstinate blenorrhœa occurs with stillicidium lacrymarum. Dropsy of the sac or mucocele also occasionally results, and must be also treated in the same way. Sometimes the puncta lacrymalia, and canaliculi are obliterated, causing stillicidium lacrymarum for life, in which event the lacrymal bone should be pierced from the inner canthus immediately inferior to the caruncula, and a bougie inserted daily until it forms a mucous tube. When the nasal or lacrymal duct becomes obstructed from such diseases, or if it is congenital, the same treatment ought to be adopted as mentioned under inflammation with suppuration of the sac; and if this is found impracticable, a small trocar and canula, as that used for piercing the membrana tympani, is to be inserted along the duct to the naris, and followed by a bougie; and if even this is impracticable from the obliteration of the duct, the anterior fossa of the lacrymal bone must be pierced with a small style, and then a bougie inserted. The after treatment is the same as that mentioned above. Some recommend the dilatation of the nasal duct in these obstructions, by a probe inserted from the lower extremity in the naris, but this is with difficulty effected. Various other modes of treatment have been recommended from the time of Fabricius to the interesting work of M'Kenzie on *Lacrymal Diseases*.

Entropeon, (from εν, and τρεπω, *to turn*,) named also entropium, ptosis, phalangosis, trichiasis, trichosis, distichiasis and tristichiasis, is an inversion or irregular direction of one or more of the eyelashes, either alone or accompanied with an alteration of the curvature of the eye lid, which produces great irritation, and even inflammation ending in opacity of the cornea, which sometimes resembles a macerated ligament. Occasionally the other eye also becomes affected. When the eye-lashes merely are attacked, it has been proposed to pull them out, and also to burn their roots; but these seldom succeed, and therefore in such mild cases, a longitudinal portion of the integuments of the eye-lid should be removed with scissors, and the wound approximated with fine ligatures and adhesive plaster. In severe cases, besides the removal of this longitudinal portion of the integuments, it is necessary to make a transverse one on each side of the inverted hairs, through the tarsus, guarding against wounding the punctum lacrymale, and healing these lateral incisions slowly by granulations. When the lower eye-lid is the seat of the disease, a transverse incision at the outer canthus is generally all that is necessary.

Ectropium or Ectropeon is an eversion of the eye-lids, commonly the lower; occasionally however both, and then the eye has an annular shape; and when confined to the upper eye lid, it is termed lagophthalmos. In mild cases, the nitrate of silver shaped like a pencil and passed along the conjunctiva longitudinally, the eye being bathed immediately after with warm water or oil, will effect a cure; but in severe cases, if the preceding treatment fails, a longitudinal portion of the conjunctiva should be removed with the knife or scissors, and a corresponding incision in the integuments made, the eye-lid brought down, and fixed with adhesive plaster, compress and bandage; care being taken that no adhesion occurs between the conjunctiva palpebræ and the eye-ball. The nitrates of silver or copper may be still necessary to establish a cure. When the lower eye-lid is everted from a scald or any cicatrix, the adhesion of the cicatrix is to be detached from the bone, and then a triangular portion of the eye-lid is to be removed, the margin of the eye-lid forming a base; and the limbs of the triangle are next approximated by suture. The edges of the eye-lids are sometimes united at birth, which is termed ancyloblepharon, and is cured by a simple division. The eye-lid occasionally adheres to the ball of the eye, and is named symblepharon, which is cured by division and preventing re-union by anointing from time to time the surfaces with olive oil.

The cornea has been found ossified, and also so convex, that the individual has not been able to see at the distance of two inches, which condition, when originating from disease, is termed myopia, and is to be remedied by concave glasses; likewise in some instances both convex and irregular on its surface, and requiring the same remedy. At other times, the cornea is flat and relaxed, which can only be remedied by convex glasses. See a most philosophical explanation of these by Dr. Brewster, in Wardrop on the Eye, Vol. I. p. 132. The eye has been transformed into a calcareous mass; the cornea, the capsule of the lens, the lens itself, the iris, the hyaloid membrane, and choroid coat have been ossified.

Under adhesion the Tagliacotian operation has been considered, and under fractures, injuries of this organ. In the article Medicine, Vol. XII. p. 815, inflammation with increased secretion of the mucous membrane is described, and we shall merely add, that venesection should be more frequently had recourse to, so as to prevent the baneful consequences of this disease. Inflammation of this membrane occasionally produces abscess of the frontal and superior maxillary sinuses. That of the frontal is characterized by violent pain in the region of the sinuses, darting along the forehead, and sometimes down the neck, with a profuse discharge of most offensive matter, intolerable both to the patient and the bystander, and convulsions or epilepsy on some occasions occur. The best treatment is the inhaling the vapour of water, the remaining in a moderately dry warm room, farinaceous diet, and preserving the bowels open. When the disease becomes chronic, the smoking of tobacco is beneficial; but if it continues severe, the sinus should be trephined, and afterwards mild warm diluents, and ultimately cold astringents injected. Abscess of the antrum maxillare also originates from carious teeth, and from injury occasioned by their extraction. It begins with acute pain in the fangs of the teeth, darting upwards to the nostril and cheek, and ultimately producing tumefaction of the latter, which then moderates the pain, while the cheek itself feels hard and painful when pressed upon, the pain often darts along the pharynx, and the patient imagines the secretion comes from them. When the patient inclines the head to the opposite side, a most offensive discharge flows out at the nostril. The external wall of the antrum becomes extremely thin, ulcerates, and then involves the muscles and integuments of the cheek, forming fistulous apertures; at other times, the matter excites absorption and caries of the alveolar sockets by which the matter is discharged; while at others the palate ulcerates and the discharge flows into the mouth. Whenever, therefore, the diagnosis clearly shows that matter has been deposited in the antrum, the second anterior molar tooth or bicuspis ought to be extracted, and the antrum perforated with a small style, but occasionally this tooth communicates with the cavity, and no perforation is required. This disease ought to be afterwards treated as recommended for abscess of the frontal sinus. If the osseous structure be carious, it becomes sometimes necessary to open the cavity freely by dissecting the lining membrane of the mouth upwards, and removing gently and carefully the diseased bone, taking care not to induce inflammation. Tincture of bark and myrrh form a good injection in such cases.

Inflammation of the mucous membrane of the nares sometimes ends in a malignant ulceration, which is characterized by pain, redness, and tumefaction, extending to the cartilages, bones, and integuments of the nose, the ulceration being first confined to the inside of the ala, and afterwards spreading both inwards and outwards, and then resembling *noli me tangere*. There is also an increased discharge of mucus, which soon becomes ichorous and fetid; the breathing is obstructed; the pain is increased by pressure, and on inserting the finger, which also produces slight bleeding. The cartilaginous septum is first destroyed, next the ethmoid bone and vomer, and ultimately all the bones entering into the formation of the nares, rendering the nose flat and disfigured. This affection, named ozæna, generally follows some syphilitic or scrofulous taint in the constitution, and prevails in the highlands, where yaws and sibbens are common. During the inflammation, it ought to be treated with the inhalation of steam, and warm anodyne injections into the nares, with fomentations and poultices externally, and with the insertion of small pieces of lint dipt in olive oil; and when the pain has been subdued, cold astringent injections and ointments should be applied, and the muriate of mercury and compound decoction of sarsaparilla administered internally. The patient should be instructed to snuff up into the nares the different injections used, and bring them round the velum, into and out at the mouth; and he should remain in a warm dry atmosphere.

Epistaxis or hemorrhage from the nares is a more serious disease than is generally supposed, proving fatal even in early life; therefore, in all cases where the bleeding is not arrested by styptics, the naris should be plugged up first at its posterior aperture into the pharynx, which is accomplished by introducing a long double canula, with a loop of silver wire along the floor of the naris, keeping close to the mesial septum, backwards to the pharynx, and downwards behind the velum palati, until the loop is felt or seen in the throat, when it is to be brought forwards by the forceps into the mouth, and then have attached to it a dossil of lint or piece of sponge, with a ligature, which is to be pulled upwards into the posterior aperture of the naris, so as to shut it up. The canula should then be removed, but the ligature left hanging out at the anterior aperture, which must be also stuffed with lint.

Polypus is a delicate fleshy tumour, of the shape of a pear, which frequently grows in the nose, either from the mucous membrane investing the bones of the nares being generally attached to the ethmoid bone, or in the antrum maxillare or in the frontal sinus. The mucous membrane appears to take on a diseased action for secreting these bodies, since they grow like fungi, or the shoots from creeping plants. In some individuals, the mucous membrane throughout is flocculent and spongy. They are variously arranged and divided by Pott, J. Bell, Ritcher and others. The delicate pale gelatinous polypus and the fleshy one adhere commonly by a small pedicle; they appear visible in the anterior nares, and can sometimes be felt, and even seen, hanging down behind the velum; and they are not attended with pain, until they press on the contiguous parts, when they produce sneezing, watery eyes, headach, stupor, and difficulty of breathing, and deafness; they destroy the ethmoid bone, the vomer, the walls of the antrum, raise the nasal bones, project the eyes out of their sockets, cause amaurosis, and ultimately prove fatal. The fleshy polypus is the most numerous. The firm, hard, dark red polypus, with a broad base, is commonly solitary, and is usually, though not always, attended with pain from the beginning, and is more frequently reproduced, than the others. Polypi are removed by excision, extraction, ligature, and caustic. The first is to be preferred whenever it can be accomplished, and should be done by seizing hold of the tumour with the forceps delineated, Fig. 9 of Plate DXVI. and gliding along them, the open limbs of curved blunt-pointed scissors, Fig. 11 of Plate DXVI. until they reach the pedicle of the polypus, which is then to be cut. If any hemorrhage occur, it is easily stemmed with the nitrate of silver, but if not, the actual cautery can be used, or the nostril plugged up. The caustic should be applied on the day following, and every succeeding day, until the pedicle is completely stunted. But if the polypus has a broad base, or plugs up the anterior naris, the knife Fig. 8, or 12 of Plate DXVI. should be employed. When the polypus hangs back into the pharynx and cannot be pulled forwards, it should be noosed by silver wire and a double canula, which are passed as recommended for epistaxis, and the noose carried around the polypus, and elevated as near its root as possible, when the wire is to be tightened. Silver wire must not be twisted, as it readily breaks, but turned round one of the rings of the canula daily. If neither scissors, knife, nor ligature can be employed for this polypus, it must be bruised with forceps, Fig. 10 of Plate DXVI; but it ought never to be extracted with the polypus forceps or any other instrument. No pulvis sabinæ or any other errhines should be used.

Polypi or sarcomatous tumours in the antrum maxillare burst open the parietes of this cell, and either force their way into the nostril, or forwards towards the cheek, or upwards into the orbit, and even into the cranium, or downwards into the mouth, by exciting absorption of the bone, or rendering it carious; and sometimes they force their way in all these directions at once, giving to the countenance a horribly distorted appearance. The alveolar processes become fungous, the teeth drop out, a fetid discharge flows, the eyes weep, are amaurotic, and even burst, and the patient is rendered wretched to himself, and loathsome to his friends. By the present mode of proceeding to remove this disease, with the exception of one or two cases, all have either died in a few weeks after this operation, or the disease has returned, so that we have proposed the entire removal of the superior maxillary bone. See Lizars's *Anatomical Plates*, Part IX. Occasionally a fungus excrescence grows from the gums, which is liable to deceive us for that originating within the antrum; but it can be easily removed and prevented from regenerating by the nitrate of copper or the actual cautery. Other tumours of a firmer consistency originate from the gums, and commonly on the lower maxilla, and ultimately involve the bone. When early perceived, the teeth should be extracted in their vicinity, and the tumour, with every portion of the diseased gum or bone, removed. The teeth being like the nails inert, inanimate objects, and in this resembling minerals, are subject only to denudation or desquamation, decay or rottenness, and lastly fractures. The other diseases usually described as belonging to them properly attack the contiguous textures.

The inferior maxillary bone is affected with encysted tumour and osteo-sarcoma; the former being distinguished by crepitation and the absence of pain, and treated like encysted tumour of the soft parts: the latter or osteo-sarcoma by the following operation: An incision ought to be made along the base of the bone, in order not to disfigure the face, when the facial artery will spring and require to be secured; the tumour and bone are then to be divested of their soft coverings, and the latter at its symphysis first sawn in a slight degree, and next broken across with Liston's forceps; having previously extracted any tooth which may interfere with the saw. The operator can then move this half of the bone outwards, divide the insertion of the pterygoideus internus from above downwards, cut across the coronoid process with the forceps, leaving the division of the insertion of the temporal muscle until the operation is nearly finished. The insertion of the external pterygoid muscle is next to be divided, keeping the back of the knife towards the internal maxillary artery, and by now depressing the symphysis, the capsular ligament may be easily but carefully cut round, and the one half of the bone removed. The coronoid process may then be detached. It is seldom necessary to remove either the condyloid or coronoid processes, but merely to saw and cut with the forceps the ramus immediately behind the dens sapientiæ. If the whole bone be diseased, the same steps are to be pursued on the opposite side, if the tumour will admit of being divided in its middle at the symphysis menti. After the removal of the bone, all arteries are to be carefully secured, the wound approximated with stitches, adhesive plaster, compress and bandage. The patient should be fed on liquids for some time, and nature left undisturbed, will repair the deficiency of bone by an exudation of callus, which will nearly remove all deformity.

Calcareous depositions are found in the submaxillary duct, which are easily extracted by an incision through the mucous membrane of the mouth and the duct; and when either these or any other causes prevent the escape of the saliva from this duct, the latter enlarges, forms a large pouch which occasionally becomes thickened in its coats, and constitutes the disease named ranula. This is to be treated by removing a portion of the sac and applying the potassa so as to obliterate it, or following the plan of Dupuytren, which is by making a puncture into the tumour, and inserting a small hollow cylinder of the shape of the eye stilette, with a small ellipical plate convex externally attached to each extremity of the tube, in order to prevent it from slipping either into the dilated duct, or out of it into the mouth.

The tongue is subject to tumours, to enlargement from mercury and small pox, to abscess, and to cancerous ulceration. Tumours are removed either with the knife or ligature, and if the former be preferred and the tumour very large, the lingual arteries ought to be first secured, or the actual cautery applied. In enlargement of the tongue, we make free longitudinal incisions, and if they do not bleed sufficiently, perform venesection at the bend of the arm, administer saline cathartics and glysters, expose the patient to a cool atmosphere, and discontinue the mercury if it be the cause. In abscess a free opening should be made. In cancerous ulceration, either the ulcerated surface or the whole tongue must be removed, with the ligature or knife; if the latter is used, the lingual arteries ought to be first secured. The ligature produces less irritation in this case than almost in any other disease. When the ulceration is trifling, a mixture of honey and water, or a weak solution of arsenic often succeeds; and if these fail, the nitrate of copper or silver, and even the actual cautery may be tried. If any of the teeth irritate the tongue, they should be extracted. Children are occasionally born with the frenum linguæ so short that they cannot suck, in which case it is to be divided with a pair of blunt pointed scissors, directing their points towards the symphysis of the inferior maxillary bone. Tumours occasionally grow from the mucous membrane of the mouth, investing the cheeks, lips, and palate, and require to be removed by the knife. The amygdalæ or tonsils frequently suppurate when attacked with inflammation. See Article Medicine, Vol. XII. p. 807, and should be freely opened with a bistoury cutting towards the mesial line, to avoid any risk of wounding the important blood-vessels in the vicinity. They are also subject to such a degree of enlargement as to require extirpation, as they impair the voice, the breathing, and deglutition. This operation is effected either by the knife, the cautery, or the ligature. When the knife is adopted, the operator seizes hold of the tonsil with the forceps, Fig. 9. Plate DXVI. and pulls it gently forwards and mesiad, while he carries the scalpel from above downwards, or from below upwards, by which the greater portion of the mass may be extirpated. Any bleeding is easily suppressed by styptic solutions, but if not, by the actual cautery or sponge held on the part. When the uvula is so elongated as to irritate the tongue and epiglottis, exciting coughing and a disposition to swallow, and even to interrupt respiration, it must be trimmed with forceps and scalpel or scissors.

Children are not unfrequently born with a cleft velum palati, which can only be remedied when they arrive at an age capable of appreciating the beneficial effects of the operation. The operation is termed velu-synthesis or staphyloraphy, and consists in rendering the edges raw, and approximating them by means of the interrupted suture. See Dr. Stephenson's *Inaugural Dissertation*, and Lizars' *Anatomical Plates*, Part IX. The partition occasionally extends between the two superior maxillary bones, and even the upper lip, exposing at once to view the nares and basis of the cranium. Children when thus malformed cannot suck, and are even with difficulty nourished on spoon meat. The cleft lip is named hare-lip, and should be operated on when the child is three or four months old, by rendering the edges raw, and approximating them with delicate sewing needles, and entwining a large flat ligature in the figure of 8 around each needle, being careful not to do it too tightly, as some degree of tumefaction must occur; a piece of lint is then to be put between the ends of the needles and the lip, and the whole gently covered with a compress and a roller. In transfixing the lip, the needle should pass as near as possible to the mucous membrane investing it, and the one near the villous part of the lip should be inserted first; the needles should be removed on the third day. When there is a double cleft, the middle portion is to be left or removed according to its magnitude; and if of such a size as is to be left, one of the fissures is to be operated on before the other, allowing two or three months to intervene. We thus perceive that in such cases of extensive malformation, all that can be done in very early life, is to cure the cleft lip; and the two sides of the face, or the superior maxillary bones might be slowly and gently approximated by an apparatus resembling the chin stay: and about maturity the cleft soft palate can be united, so that if any fissure remained in the hard, its edges might be rendered raw and approximated, or if impracticable, a piece of sponge and silver plate, or simply a silver plate with a groove round its margin might be inserted.

The lips, particularly the lower, are very subject to cancerous excrescence and ulceration, which if not early removed, soon contaminate the contiguous lymphatic glands, rendering an operation hopeless. When the lower lip is the seat of disease, the cancerous portion, with some of the healthy structure on each side, requires removal, and is done by making two incisions of the figure of the letter V, the apex pointing towards the chin, and approximating the raw surfaces as described above.

The nerves of the face, viz. the supra-orbitary, infraorbitary, mental and facial, are all liable to be affected with neuralgia, or tic douloureux, which is a peculiar excited state of the nerves, being either an inflamed condition of the neurilema, or a spasmodic condition of the medullary structure, and often results from a deranged state of the stomach, or rest of the alimentary canal or liver. The treatment therefore depends on the cause; if not constitutional, the best local application is the moxa, the next the knife. For an account of the various operations, see Lizars' *Anat. Plates*, Part. II.

The face, from its glandular structure, is very subject to tumours, warty excrescences, and cancerous ulceration, all of which should be early excised; and in performing operations in this region, we must be careful to avoid the parotid duct, and disfiguring the face. When the parotid duct is wounded, the saliva discharges itself over the cheek, constituting salivary fistula, and is to be treated by establishing a fistulous aperture into the mouth by means of a seton, then closing the external wound towards the cheek by caustic, actual cautery, compress and bandage. The parotid gland, and particularly the lymphatic ones superficial to it, are frequently scirrhous, and require extirpation. Some we have known remain dormant for thirty years, while others have advanced to ulceration, and produced a most painful and loathsome existence. In removing the parotid gland with the knife, the common carotid of the affected side ought to be first compressed or secured, then an incision over the gland, from the zygoma downwards to the sternomastoid muscle, or two semi-elliptical ones, according to the magnitude of the tumour. The skin dissected, first forwards towards the face, and next backwards towards the ear; and the gland carefully insulated by lateralizing the knife with its cutting edge towards the chin, and preserving the nervus vagus and internal jugular vein, both of which may be so embedded in the tumour, as to require a portion of the disease to be left. It has been removed repeatedly with success.

The submaxillary gland, or its contiguous lymphatic glands, are subject to the same diseased condition as the parotid, and also require removal with the knife; but as there is only the facial embedded in the tumour, there is no necessity for securing the carotid. The lingual, however, may be wounded in the operation. The knife should be lateralized in the same manner as recommended for the parotid. The different lymphatic glands in the region of the carotid artery, are very subject to the various sarcomatous enlargements, particularly the carcinomatous, and require extirpation. Those at the angle of the inferior maxilla, are frequently so braced down by the sterno-mastoid, and the platysma myoides muscles, together with the cellular fasciæ, that they are in close contact with all the important blood-vessels and nerves in this region, while they appear to be immediately under the skin. In removing them, the knife is to be lateralized as mentioned above. In the lower region of the neck, and near the axillary plexus, tumours are generally softer, occasionally encysted and cartilaginous.

The enlargement of the thyroid gland, which depends on the water drunk by the individual, is now found curable by iodine, and a removal to a distance from the water which produced it, avoiding, however, every danger of falling into Charybdis. Wry-neck is a contraction of the sterno-mastoid muscle, which then requires to be divided. Sometimes only the clavicular attachment need be separated; but if the whole muscle, either its origin or insertion should be selected, and the latter is less dangerous; and if the operator proceed cautiously, he will injure no important objects. After the operation, the chin-stay, Fig. 22 of Plate DXVI. should be worn.

While in the act of eating various substances, especially fruits, the stones are liable to be swallowed and enter the larynx, and unless removed, immediately produce suffocation, by entering the glottis, or sacculus laryngis; or they descend into the trachea, and produce difficult respiration, inflammation, effusion, and occasionally emphysema. They even sometimes descend into the minute divisions of the bronchii, and produce abscess of the lungs, or phthysis pulmonalis. As suffocation may be produced by bodies arrested in the pharynx, a probang should be first inserted into it, but if the suffocating symptoms continue, laryngotomy ought immediately to be performed, which consists in making a longitudinal incision over the thyro-cricoid membrane, and securing any small arteries, if necessary; then making an incision in this ligamentous membrane, and searching for the foreign body. If it be below the incision in the trachea, the efforts of coughing will bring it up; and if in the ventricles of the glottis, a probe scoop, or forceps will dislodge it. Any incision of the thyroid, or even cricoid cartilage, is to be as much as possible avoided, especially the former. Laryngotomy is also performed when foreign bodies have been arrested in the œsophagus, threatening instant suffocation, and the operator unable to dislodge them by the probang; it is also adopted to inflate the lungs in suspended animation, likewise in laryngitis. See Article MEDICINE, vol. XII. p. 807. And when the glottis is ulcerated in syphilis, or too much mercury has been taken, and when tumours in the vicinity oppress the breathing. With the exception of the first of these cases, laryngotomy appears unnecessary; and when performed, a trocar and canula, as delineated in Fig. 18, Plate DXVI., should be plunged obliquely downwards into the trachea, after the oblong square space is brought into view, the canula left and the trocar withdrawn.

Tracheotomy is performed for supended animation, foreign bodies in the trachea, and œsophagus, chronic laryngitis, and trachitis; but, with the exception of the three last of these affections, laryngotomy is to be preferred. This operation is done by making a longitudinal incision in the mesial line of the trachea, through the integuments, when the operator should feel that there be no artery pulsating, as the innominata and right carotid may come in the way of the knife. He must then proceed cautiously, avoiding the isthmus of the thyroid gland, and plunge the trocar and canula through the rings of the trachea obliquely downwards, withdrawing immediately the trocar.

During mastication and deglutition, fish and other bones, pieces of flesh, &c. are sometimes arrested in their progress to the stomach, either in the pharynx or œsophagus. Fish bones are generally found sticking in the fauces or pharynx, so also are needles, pins, and fish-hooks; while bread, bone, flesh, gristle, cheese, coins, and other large bodies, are arrested where the pharynx becomes œsophagus; and when these objects are very large, they often produce instant suffocation; if not, they excite inflammation and suppuration, or gangrene, which ultimately prove fatal. But sometimes an abscess forms in the neck that bursts externally, from which they are discharged; at other times they are spit up, or fall into the stomach, and if insoluble, they are generally arrested in their course along the alimentary canal, and excite inflammation, ulceration, gangrene, and death; pins and needles, however, occasionally travel with impunity over the whole body, when some are expelled per anum, others per urethram, others again through the skin, and some have been known to produce fistula in ano. When they are soluble in the gastric juice, and not sharp-pointed, they should be pushed down by the probang into the stomach; but if otherwise, they ought to be pulled up into the mouth, either with the common polypus forceps, or with a hank of thread doubled; so as to form a number of loops, and fastened to the probang, or with the hook end of that instrument. If the object arrested in the pharynx cannot be dislodged, and if it threatens suffocation, the operation of pharyngotomy ought to be performed, which is done by making an incision through the integuments and platysma myoides, on that side of the neck where the body projects most, parallel with the tracheal margin of the sterno-mastoid muscle, avoiding the external and internal jugular veins, the common carotid artery, and the nervus vagus, which ought to be held aside towards the dorsal aspect by an assistant, when the prominent object will appear, which should then be liberated by an incision through the muscular and mucous tunics of the pharynx. The knife should be lateralized with its edge towards the trachea. The external wound is afterwards approximated by adhesive plaster, the patient kept extremely quiet, nothing allowed but milk or water for some days, which must be introduced into the stomach by an elastic tube, or the patient supported by injections of nourishing soups, per rectum.

The mammary gland is generally the seat of disease in the female, but rarely in the male. It is subject to phlegmonous and erysipelatous inflammation, to mammary abscess and sinuses, to excoriation and ulceration, to lacteal swelling, to the various species of sarcoma, to hydatid or encysted swelling, to cartilaginous and ossific tumour, to hypertrophy, and to simple chronic tumour of the mamma. Inflammation of this gland is to be treated in the same manner as formerly recommended under inflammation; and the reader is also referred to the Article Midwifery. The treatment ought to be active and prompt, as all glands are easily and rapidly ruined in their functions by an injury done their structure. Under inflammation it is stated that coagulable lymph was effused, which in glandular texture unites its conglomerate portions in such a manner as to suspend the functions in the first place, and in the second to obstruct too often the secretion ever afterwards. The coagulable lymph lays the foundation for future diseased organization, and forms the substratum of the diversified variety of tumours, and in those tumours where no acute inflammatory action is present, a chronic state exists, which converts the secretion of the capillary vessels of the affected part from their natural to the diseased condition which they respectively assume, in precisely the same way as acute inflammation disposes these capillaries to secrete lymph or pus. This appears a simpler explanation, than Adams's multiplication of hydatids, or Dr. Baron's conversion of encysted hydatids into tubercles. For the phenomena and treatment of mammary abscesses and sinuses, see acute abscess, for in no respect do they differ from those occurring in any other part of the body, with this exception, that sinuses of the mamma should first be tried to be cured by injections of diluted acids. Exfoliation of a rib has supervened to deep abscess of this gland. Mammary inflammation and abscess occur most frequently within the first three months after parturition. A deep-seated abscess is described by Hey, but this is simply a chronic species of it. The excoriation and ulceration which attack the nipple are to be treated like ring-worm, tinea capitis, or noli me tangere, according to their severity. Lacteal swelling of one or more of the lactiferous ducts requires to be punctured.

The mamma is peculiarly subject to the sarcomatous tumour, which is divided by Mr. Abernethy into the common vascular or organized, the adipose, the pancreatic, the mastoid or mammary, the tuberculated, the pulpy or medullary, and the carcinomatous. Of these various sarcomatous tumours, the pancreatic, the medullary, and the carcinomatous chiefly affect this gland. The pancreatic attacks the portion situated between the nipple and the axilla, and ultimately involves the axillary glands. It is either quite indolent or very active; and when the latter is the case, there are severe lancinating pains with an inflamed state of the skin, which produce fever and undermine the health. The treatment is to reduce the cutaneous inflammation and constitutional febrile excitement, and then to extirpate the whole mammary gland, together with the axillary. The medullary sarcoma or fungus hæmatodes is characterized by its elastic feeling, nodulated appearance, some portions being inflamed, others indolent, and some again natural. The elasticity of this tumour often deceives the practitioner for matter, but it consists of a brain-like substance, cartilage, bone, flesh and blood. This species also involves the axillary glands; occasionally it is as encysted as the common wen, and may then be removed by the scalpel with every chance of success.

The carcinomatous sarcoma, or scirrhus, or occult cancer, attacks this more frequently than any other gland, and is characterized by an unequal knotted hardness, diminished bulk, and a puckering or depressed appearance of the nipple, while the skin remains in a natural state. These phenomena constitute the indolent state of the scirrhous mamma, but when it assumes the malignant disposition, there are most acute lancinating pains, the skin acquires a purple hue in some spots, and the veins of the skin become enlarged and more or less varicose, and is then termed occult cancer. Whenever ulceration takes place, it is denominated open cancer, which generally occurs before the mass has acquired any great magnitude, when it now forms irregular sloughs, or ulcerates and sloughs in different places; has everted irregular hard edges, with a violaceous coloured inflammation around; and the discharge is thin, dirty green, and ichorous. The axillary glands are commonly affected immediately after the disease becomes occult cancer, and they soon afterwards contaminate those under the claviele and in the neck; and even all the subcutaneous, for it is a mistaken idea to suppose that ulceration must precede the contamination of the axillary glands. The affection now becomes constitutional, extending to the glandular system of the thorax and abdomen, and even to the pleura costalis and ribs; but by some authors these constitutional symptoms are supposed to take place at an earlier period. When the constitution is affected, the patient feels pains darting along the spine, and has cough with difficulty of breathing. This species commonly begins in a small spot at the nipple, and extends around in all directions like the radii of a circle, ultimately involving the whole mammary gland, the skin, the cellular substance, the muscles, the lymphatic glands, &c., for there seems no disposition to this horrible disease in the surrounding parts prior to the actual carcinomatous action. In some rare instanees this disease is sacculated. When the tumour after removal is bisected, it presents a hardened glistening appearance, with firm white bands intersecting it in all directions, either like radii or irregular bands, or in an arborescent manner; the whole very much resembles cartilage. This species generally attacks the female when the catamenia cease, between forty and fifty years of age, but occurs occasionally at its first appearance, when the pains are aggravated at every period of menstruation. It may be produced at any period of life by a blow, or succeed mammary inflammation and abscess. This species of tumour may be attempted to be discussed by the repeated application of leeches, especially when the catamenia are expected to take place, and by anodyne fomentations, poultices, low diet, and gentle exercise; and when pain has been subdued, by local pressure. But the tediousness and anxiety are such, that most patients demand an operation, which, without doubt, is the safest.

The patient should be laid on a table, and the arm of the affected side elevated towards the head with the hand supinated; two semi-elliptical incisions are to be made from the axilla to the sternum, so as to include all diseased skin, and to leave if possible enough to cover the wound, and the lower or sacral made first. These incisions should extend through the skin and cellular substance to the fascia of the muscle, dissecting the lower from the gland first, and defining clearly both angles. A few sweeps of the scalpel from above downwards will remove the whole gland, all of which ought to be invariably extirpated. Sometimes the muscle itself is affected to a considerable extent and requires removal. During the removal of the tumour, an assistant should put his fingers on the bleeding arteries, which ought now to be secured. The edges of the wound are then approximated either with ligatures or adhesive straps, according to the deficiency of the integuments; compresses of lint, together with a roller around the trunk, supported by two shoulder straps or braces are lastly applied. If there have been many small arteries wounded, and not all secured, a second roller should be applied, and tighter than the first, and which must be removed in a few hours, for whenever re-action takes place, respiration becomes affected. The wound to be dressed on the third or fourth day. When the axillary glands are diseased, one of the external incisions should extend over them at the outset of the operation; but they ought not to be cut out till the removal of the mammary gland, and the knife should run parallel with the axillary vein, with its back to the vessel. Whenever an artery springs in this region it ought to be secured; and even if a vein bleed freely, a ligature must be thrown around its mouth. There is a cutaneous variety of cancer which attacks both the male and female promiscuously.

Ascites has been already treated of in the Article Medicine; and when diuretics and cathartics fail to remove the effused fluid, paracentesis abdominis should be performed, and these remedies afterwards still persevered in. This operation consists in surrounding the abdomen with a belt of strong calico, which is to keep up an equable pressure during the flow of the fluid. The patient is to sit on the edge of a chair, when the operator pierces the abdomen with a trocar and canula, in the direct line of the linea alba, midway between the umbilicus and pubes, and removes the trocar. If the patient becomes faint during the flowing of the fluid, the bandage should be tightened, and the finger applied to the mouth of the canula for a few seconds. When all the fluid has been evacuated, the canula is withdrawn, a compress of lint applied to the wound, with a larger one of calico, and the ends of the bandage brought firmly round and pinned. The greatest care must be taken that the compression prevents any further flow of the fluid, for it collects with rapidity, and would soon exhaust life if the discharge continued. The best canula is that made of steel, the size of a hen's quill in diameter, and the round is superior to the flat. After paracentesis abdominis, if any inflammation follows, leeches, with warm fomentations to the abdomen, and, if necessary, the lancet, castor oil, low diet, and the warm bath. Many of the acute diseases affecting the abdominal cavity are detailed under MEDICINE. When knives or such foreign bodies are swallowed and lodged in the stomach, and appear to involve the life of the individual, they should be extirpated by cautiously making an incision in the line of the linea alba from the ensiform cartilage to the umbilicus, through the integuments and tendons of the muscles to the peritoneum, which is then to be carefully punctured, and one or two fingers inserted into the abdominal cavity, and this membrane divided to the same extent as the integuments. The stomach is next to be gently raised with the left hand, and opened with a transverse incision, and the foreign body taken out. The external wound is then to be stitched with broad ligatures, at the distance of an inch from each other, and the needle, Fig. 17 of Plate DXVI. passed immediately superficial or peripheral to the peritoneum, compresses of lint applied, and a large handkerchief rolled round like the binder after parturition. The patient should be nourished for three or four weeks, or even longer if his constitution can bear it, with animal jellies, soups and milk injected per anum. This operation is termed gastrotomy.

When laudanum or other narcotic poisons are swallowed, they should be discharged from the stomach by the stomach-pump delineated in Fig. 12 of Plate DXV. The surgeon puts the fore and middle fingers of his left hand into the mouth of the patient and presses gently on the tongue, while with his right hand, he glides the tube marked *a* over the tongue into the pharynx, œsophagus and stomach, and then proceeds to pump out of the latter viscus its contents with the syringe *b*. The gag of wood *c*, ought to be in the mouth to prevent it from injuring the tube. If the contents of the stomach are scanty, or of a thick consistence, warm water should be first injected into it, by putting the end of the syringe into a basin full of warm water, and joining the two tubes *a*, *d*, together. By alternately filling and emptying the stomach in this manner, it may be fully divested of every drop of the narcotic fluid; and when this has been accomplished, a tea-cupful of strong coffee ought to be injected, and allowed to remain; the patient kept walking about his room between two attendants; and his bowels afterwards freely opened. In some cases, it is necessary to apply a blister to the region of the stomach.

Ileus, volvulus, or intussusceptio, is already described under MEDICINE, and if the remedies mentioned there fail to effect a cure, we should first try large enemata of a weak infusion of tobacco, pressing the caput cœcum coli at right angles in order to overcome the valve: and if these enemata likewise fail, we seem justified in opening the abdomen and disentangling the viscus. This operation ought only to be performed in the adult, as children in the last stage of tabes mesenterica have occasionally from one to seven intussusceptions.

Calcareous concretions are occasionally deposited in the colon, and if our diagnosis is clear, they ought to be removed by gastrotomy. The spleen is subject to prodigious enlargement, which sooner or later destroys the individual; and if iodine, mercury and other medicines fail to reduce it, gastrotomy may be considered. In this case, whenever the enlarged spleen is brought into view, its plexus of vessels should be secured by a ligature, both ends of which are to be cut off. Abscess of the liver is a frequent termination of hepatitis (see MEDICINE), and when clearly indicated, should be freely opened with a bistoury; and the nitro-muriatic acid pediluvium, or the alterative course of mercury continued. Biliary calculi have been proposed to be extracted by an operation.

Nephrotomy, or the removal of calculi from the kidney was proposed in 1696, but has never been performed until the calculus has produced inflammation and suppuration with a prominent tumour. Many die before such a result takes place, from the urine diffusing itself between the peritoneum and the parietes of the abdomen. Sometimes a communication is established between the pelvis of the kidney and the colon. When a calculus is arrested in its progress along the ureter, it generally soon proves fatal, by exciting inflammation, suppuration and ulceration; but occasionally it advances to the external parietes of the abdomen, and is discharged near the umbilicus, or pubes, or crista of os ilium. Various kinds of tumours grow in the abdominal cavity, as the fatty pendulous, and the medullary sarcoma; the latter of which affects the kidneys, and the mesenteric glands.

Hernia or rupture is commonly applied to a protrusion of one or more of the abdominal viscera, either at one of the natural apertures of the abdomen, or at some preternatural one; and in the majority of cases, there is a sac formed by the peritoneum. Hernia is applied also to a protusion of the thoracic viscera. It is estimated that one-eighth or one-sixteenth of mankind are affected with rupture, young and old, male and female indiscriminately, and in every condition and mode of life. It is not immediately dangerous, but the least exertion is liable to render it fatal, and it too often keeps up such a determination to the intestines, that they either become strictured, tuberculated or ulcerated, and then cause death. Hernia is divided first into the reducible and the irreducible; the former signifying the possibility of reducing the protruded viscera into the abdominal cavity; and the latter or the irreducible, the reverse. The irreducible is subdivided into the simple irreducible, the irreducible with obstruction, and the irreducible with strangulation or incarceration. The viscera, which are protruded, are the omentum, then named omental hernia or epiplocele; the intestine, named intestinal hernia or enterocele, and these two viscera conjointly entero-epiplocele. When the stomach is the protruded viscus, gastrocele; the liver, hepatocele; the spleen, splenocele; the urinary bladder, cystocele or hernia vesicæ; and besides these, the uterus or ovarium, or both, in conjunction. The omentum and the intestines are those most commonly protruded; the omentum the most frequent, next the ilium, then the jejunum, and lastly the colon. The apertures of protrusion are, the inguinal canal, the crural or femoral aperture, the umbilicus, the great sacro-ischiadic notch, and the foramen ovale. Sometimes one of the apertures of the diaphragm, and occasionally a gap in the muscular parietes of the abdominal cavity. When the viscera are forced out at the inguinal canal, either in the male or female, it is named bubonocele, or incomplete hernia, and when into the labium pudendi or into the scrotum, complete hernia; that into the scrotum is termed also scrotal hernia or oscheocele. When the viscera do not descend along the inguinal canal, but protrude opposite the external aperture, it is named ventro-inguinal or direct or internal hernia; and when they merely enter the inguinal canal, but do not appear externally, it is denominated internal hernia. Male children are occasionally born with inguinal hernia, which is then named hernia congenita, or hernia congenita infantilis; and this as they advance in life, is liable to be complicated with common inguinal hernia. When the viscera protrude at the crural foramen, it is termed crural or femoral hernia, or merocele; the protrusion at the umbilicus, umbilical hernia, exomphalos or omphalocele; and when the viscera are forced out at any muscular gap, ventral hernia, which protrusion generally occurs at the linea alba. Hernia may be said also to exist within the abdominal cavity, when a portion of the intestine is entangled by the omentum, the latter of which in such a case commonly adheres to the muscular parietes in the region of the inguinal or femoral aperture. Two or more hernia not unfrequently exist at the same time, generally double inguinal, *i. e.* an inguinal rupture on each side; and there are instances where three protrusions have existed in one inguinal region. The assigned causes of hernia are exceedingly numerous, but they may be reduced to violent muscular exertion, and a more than natural size of aperture, in consequence of a relaxation of the muscular fibre; and hence hernia is as hereditary as scrofula or phthysis pulmonalis. In scrotal hernia, the peritoneal sac has descended to the knee, in which case it becomes so remarkably thin, that the vermicular motion of the intestines has been seen through the integuments, and a blow inflicted on the tumour has ruptured it; the omentum, jejunum, ilium, colon, and even the pyloric orifice of the stomach, have been found in it; and if the sac adhere intimately to the ring, the fundus is occasionally lacerated, forming as it were small cysts or secondary cavities, and if the neck of the sac yields and descends, a new neck is formed, and thus two or more constrictions are produced. The sac very early forms adhesions to the contiguous cellular substance, and through this means to the neighbouring organs, uniting in a mass the integuments, cremaster muscle, sac, and even the intestines in the inguinal hernia. By some the sac is said to become thickened, but this only occurs in small old hernia; in large hernia, the cellular substance is generally thickened, but not the sac. When the caput cœcum coli, the sigmoid flexure of the colon, or the urinary bladder is protruded, there is commonly no peritoneal sac.

The symptoms which distinguish reducible hernia from the numerous affections with which it is liable to be confounded, are a colourless tumour in the region of one of the abdominal apertures, or even at any part of the abdominal cavity capable of being returned with the fingers, varying in size before and after meals, and in the mornings and evenings, influenced by coughing, and disappearing in the horizontal position; and the patient is frequently troubled with colic. Its treatment consists in reducing the protruded viscera into the abdomen, which is termed the taxis, and is performed by placing the patient on his back, in the horizontal position, with his head and shoulders and knees so elevated, as to relax the abdominal muscles and the fascia lata femoris; and by pressing with the fingers upwards and outwards in inguinal hernia, and centrad upwards and inwards in crural hernia. Pressure first near the neck of the sac, and then on the body of the tumour, sometimes succeeds, but various other ways are recommended, which in our estimation appear fanciful and absurd. Then applying a rupture bandage, Fig. 24 of Plate DXVI. which ought to be worn day and night for life, together with the application of oak bark decoction for three or four months, (See *Edin. Med. and Surg. Journal*, vol. xviii.) These will in nine out of ten cases effect a radical cure.

By irreducible hernia is understood the impossibility of returning the protruded viscera into the abdominal cavity, in consequence of their having either remained so long down in the sac as to have become swollen, and hence too large, or contracted adhesions with the contiguous structures and the different viscera; the omentum is the most frequently so situated, next the caput cœcum, then the sigmoid flexure of the colon, and lastly, the urinary bladder. In this species of hernia, as the patient's life is constantly endangered, every attempt should be made to reduce it, and the bowels ought to be first unloaded by means of a cathartic; but we often fail, and if the mass protruded be very large, the patient cannot suffer it to be returned, in consequence of the abdominal cavity having become habituated to a smaller quantity of intestine, and to persist may prove fatal. The patient must be exceedingly circumspect in his diet, his regimen, exercise, and all his conduct; and should support the mass with a T bandage or suspensary truss. Long confinement to bed, light spare diet, occasional bleeding, purgatives and glysters, have succeeded in returning the protruded viscera; so also has the employment of trusses with hollow pads gradually reduced in size, together with confinement to bed; likewise rest in the horizontal position, combined with suspensary bandages progressively diminished in size. The application of ice has also succeeded. An operation has been likewise performed, but from the peritoneal inflammation which followed, it ought not to be done unless absolutely necessary. The great Zimmerman nearly fell a victim to this operation, and the illustrious Gibbon preferred carrying his load along with him to the grave. In some of these large irreducible hernia, so great a quantity of serous effusion takes place at the fundus of the sac as to require to be drawn off with a trocar and canula.

In this irreducible hernia, if the protruded intestine becomes overloaded with feces, and an impediment be produced, or a fresh portion of this viscus or omentum be forced out, strangulation may occur; again, in the reducible hernia, if a greater portion of viscus be protruded, and the bowels be loaded with feces, which may be only a portion of the diameter of the intestine; while again, in a recent hernia, if the aperture be too small to permit the return of the viscus, the same event may take place, strangulation may also ensue. Inflammation is soon excited, which causes thickening of the coats of the protruded intestine, and interruption to the circulation of the protruded omentum, an effusion of bloody serum in the herniary sac, coagulable lymph on the intestine, with adhesion of the parts to each other, and ultimately mortification; while within the abdominal cavity, the inflammation extends to the intestines above the seat of the stricture, and to the peritoneum, both of which generally become coated with coagulable lymph, and more or less serous effusion is deposited. The strictured portion of intestine almost immediately assumes a dark purple colour, in consequence of its venous circulation being arrested, and soon becomes black and brown, and then ruptures; the portion of intestine above the seat of the stricture within the abdomen becomes also purple and black, approaching nearly to gangrene, while that below the seat of the protrusion retains its natural colour. When the omentum is the protruded viscus, its circulation becomes also strangulated, and produces inflammation, mortification, and death. If the patient has not previously fallen a victim to the derangement thus produced in his system, the strangulated portion of the intestine mortifies and ruptures, the feces are diffused in the neighbouring cellular tissue, which produce sloughing of the integuments, and are thus discharged, forming an artificial anus; or the integuments over the intestine inflame, mortify and ulcerate. In some cases the feces are so extensively diffused in the cellular tissue of the thigh, as to produce erysipelas phlegmonodes, and death. In those instances where a portion of the diameter of the intestine is merely strangulated, the feces not only escape by the mortified aperture, but also descend naturally along the intestine to the anus.

The symptoms of strangulated intestine are obstinate constipation, pain in the tumour extending from thence over the whole abdomen, aggravated on coughing, sneezing, pressure, or any movement, nausea, vomiting, small, quick, and hard pulse, anxiety, restlessness, thirst, and general inflammatory fever. These are soon followed by hiccup, cold extremities, cessation of the pain, cadaverous countenance, imperceptible pulse, feeble respiration, cold clammy perspiration and death. Strangulated hernia is as liable to be confounded and complicated with other diseases as reducible hernia, so that we require to be very circumspect in our diagnosis; and probably, of all such affections, a swollen inguinal gland, accompanied with obtinate constipation, is the most frequent, and at the same time the least dangerous, for even, provided an operation is performed in such a case, no evil would be produced.

Let us suppose it to be purely strangulated inguinal hernia, the taxis is to be first employed, and if there be not much pain, it may be persevered in for some minutes; but if the reverse occurs, venesection even to fainting should precede the taxis, and if a warm bath can be procured, it ought to precede blood-letting. He ought to be bled while immersed in the water, and the taxis tried while in it. If he does not faint when the ordinary quantity for producing this effect has been abstracted, he ought to be raised to the erect attitude, and the instant syncope takes place, to be seated in the bath and the taxis employed. The tobacco enema may be combined with blood-letting to produce fainting in this disease, but is objectionable as it retards an operation. Purgative enemata should be employed. The time which is to be allowed in the employment of the preceding measures must be regulated by circumstances; more patients, however, fall victims to delay, than to an operation. We should operate immediately if the pain increases after giving a fair trial to the taxis combined with blood-letting, for perseverance in the taxis may produce suppuration, gangrene, and rupture of the intestine, and we allow the opportunity to pass of saving our patient by an operation. Small herniæ are more difficult of reduction than large, in consequence of the smallness of the aperture. We must be careful not to be deceived in reduction, for sometimes, only the contents of the intestine are returned; in other instances, only one of the viscera; at others, the intestine is still in the inguinal canal strangulated; in others, although the sac and intestine are returned, still the neck of the sac continues to incarcerate the intestine; in others the omentum bridles down the intestine and strangulates it; in some ileus may be combined; while sometimes there exist two distinct herniæ, and the contents only of the one are reduced. The symptoms consequently ought to be our guide, but here also we may be deceived, for after reduction, although the patient is relieved from his immediate sufferings, inflammation may continue from the effect of the stricture. If therefore pain with vomiting still continues after reduction, strangulation must exist, and an operation is required, and if after that operation these symptoms are not abated, either the omentum must be bridling down the intestine or ileus exist, and then the propriety of gastrotomy must be considered. When the mesentery within the abdominal cavity is the cause of strangulation, the case is named mesenteric hernia, and when the mesocolon, mesocolic, and that formed by the omentum may be termed internal omental hernia.

The operation to relieve strangulated inguinal hernia is performed by making an incision from a little above the tumour down to its lowest point, carefully through the skin and cellular substance; then pincing up with the fingers at the lowest portion any cellular tissue, and cutting it horizontally with the scalpel, until the sac or intestine appears, for in some cases we have said there is no herniary sac, but when present, it is of a whitish colour, while the intestine is purple. We must likewise be on our guard in case of the spermatic cord running superficially to the peritoneal sac. The sac is next to be divided in the same cautious manner, when a bloody serous fluid generally escapes, and afterwards cut up to the seat of the stricture, with a probe-pointed bistoury represented in Fig. 8 of Plate DXVI. The portion of the muscle forming the seat of the stricture, which in a recent small hernia is commonly the transversalis, while in an old large hernia the external oblique, is now to be divided directly upwards with the same bistoury, but in some cases only the sharp-pointed bistoury can be admitted. The viscera are now to be returned, reducing that first which protruded last; thus if both intestine and omentum are present, the former should be first replaced, and in doing so, considerable difficulty is generally experienced, in consequence of the action of the diaphragm and abdominal muscles forcing it out as soon as replaced. The edges of the wound are to be approximated with sutures passing the needle through the muscles, then applying adhesive plaster, lint, and bandage. The nates are to be elevated above the level of the body when the patient is put to bed, and as mild diarrhœa commonly follows, a gentle laxative, as castor oil, should be given; and since inflammation frequently supervenes, if the patient has not lost much blood, venesection ought to be performed. The other remedies adopted in this affection are to be kept in view, and the diet should be low for many days. When the individual has recovered the operation, he must wear a rupture truss for life.

There are many points to be attended to in this operation; thus the spermatic cord sometimes descends in front of the tumour running on the sac, but generally it separates into its constituent parts, the plexus of nerves and blood-vessels lying on the inner and anterior aspect, and the vas deferens on the posterior and outer aspect; while in other cases, this order has been reversed. In the ventro-inguinal hernia, the epigastric artery runs on the outer or iliac aspect of the neck of the sac. At the period of reducing the protruded viscera, we should examine carefully that two herniæ do not exist, or that there is not a second protrusion near the same aperture. We must be also guarded against pushing the viscera between the abdominal muscles, or between the muscles and peritoneum, instead of into the abdomen, which is termed by the French *reduction en bloc*. We must be satisfied that the viscera are returned into the abdominal cavity; adhesions are occasionally formed between the portions of intestine, or the intestine and omentum, or between these and the herniary sac, and if recent or of trifling extent, they should be carefully separated by the scalpel, but if the intestine adheres intimately and extensively to the sac, the stricture is to be freely relieved, and the intestine covered with the integuments, when nature will afterwards reduce it. On the contrary, sometimes an artificial anus is the result. The colour of the protruded intestine ought to be no criterion with regard to reduction; unless it breaks down or ruptures under the fingers, it should be reduced: the colour of a gangrened intestine is commonly brown. The omentum sometimes surrounds the intestine in such a manner as to require to be disentangled. The omentum is also occasionally so consolidated, as to be incapable of being returned without making a prodigious aperture, and even when returned, it has excited inflammation, suppuration, and mortification. It should therefore be excised, and if the vessels bleed, which are here chiefly veins, they must be secured. A serous fluid is not invariably present in a herniary sac, neither is the herniary sac itself, and in those latter cases, when the colon has been the viscus, it has been proposed not to return it, which, in our opinion, appears injudicious. In a large hernia, the sac should not be opened, as the neck is large enough to allow the reduction of the viscera, and would expose too large a surface; all that is requisite, therefore, is to divide the stricture formed by the muscle on the outer side of the neck of the sac. Congenital inguinal hernia is of most importance when it occurs in the male, and consists in a protrusion of the viscera, within the tunica vaginalis testis, either with or without a peritoneal sac, and, consequently, in some instances, in contact with the latter body. In children, as the testis cannot be felt before the viscera are reduced, we require to be careful in the application of the truss; and as children are subject to hydrocele, and these diseases frequently co-exist, equal caution is requisite. When this variety becomes strangulated, the sac should not be laid open from the bottom, but at the upper margin of the testis, in order that enough may be left to cover the gland: but if any adhesion exists, the sac must be cut open to the bottom. Sometimes a common inguinal and a congenital hernia exist together.

Crural hernia is said to be peculiar to the female, and inguinal to the male, although our own observations do not corroborate this. The viscera are protruded either at the crural aperture, or in the sheath of the femoral vessels, but much more frequently at the former than the latter place. The stricture in this hernia is generally caused by Gimbernat's ligament, and requires to be divided horizontally towards the pubes, inserting Weiss's probe-pointed bistoury, Fig. 12 of Plate DXVI. as short a distance as possible within the abdomen. There is seldom any serous fluid effused in the sac of femoral hernia, and intestine more frequently than omentum is protruded. The constriction produced on the intestine by the crural aperture, has sometimes caused either permanent contraction of the part, or ulceration of the mucous and muscular tunics, followed by fatal extravasion.

Umbilical is fully more frequently congenital than inguinal, and great circumspection, therefore, is required in securing the umbilical cord at birth. The peritoneal sac in this species becomes exceedingly thin, and is often ruptured, forming cysts, and the viscera, not unfrequently, adhere to the integuments, and have been strangulated at these foramina of the sac. It is not very liable to be strangulated, but when this event does occur, the symptoms are more violent, and gangrene takes place more rapidly than in the preceding species, and hence an earlier operation must be had recourse to. The stricture is to be divided either directly upwards or downwards in the linea alba, but the latter should be preferred. Ventral hernia commonly occurs in the linea alba near the umbilicus and between it and the ensiform cartilage. Perineal hernia is when the viscera protrude between the urinary bladder and the rectum in man, and between the rectum and vagina in woman, rupturing the fibres of the levator ani muscle. Vaginal hernia is when the viscera descend either between the urinary bladder and uterus, or between the uterus and rectum. Pudendal hernia is when the viscera protrude between the ramus of the ischium and vagina through the fibres of the levator ani muscle, the tumour appearing a little below the middle of the labium externum. Sacro-rectal hernia is a peculiar species arising from an incomplete ossification of the sacrum.

If the intestine which is protruded becomes gangrenous and ruptures, an artificial anus is formed, and if this portion be even so near the anus as the ileum, close to the caput cæcum, the patient dies from inanition. If the intestine at either end admits the little finger, there is no necessity for dividing the stricture, if otherwise, there is. The palliative treatment consists in cleanliness, in stopping up the external aperture by sponge or linen plugs, and ultimately, when the aperture of the intestine is reduced to a small foramen, by applying the actual cautery, and nourishing the individual with nutritive soups and enemata; the radical cure, in destroying the septem with Dupuytren's forceps, delineated in Fig. 16 of Plate DXVI.; but this instrument ought not to be used too soon after the formation of an artificial anus, and if inflammation is induced, it must be subdued by local blood-letting, fomentations, &c. The external wound is to be afterwards healed by pressure, caustic, and the actual cautery, or paring the edges and employing a suture. Dupuytren uses an instrument consisting of two pads and a screw, to approximate the sides of this fistulous aperture.

Retention of urine, or ischuria vesicalis is, when the urine is collected in the bladder and cannot be expelled; and is either partial or total, or complete and incomplete. Partial or incomplete retention is when the patient voids a little urine from time to time, but still his bladder is becoming more and more distended with water, a condition very deceitful and equally dangerous as the complete, and hence very improperly named. The complete or total state is, when no urine whatever is voided. The causes of this malady are, inflammation of the neck of the bladder or urethra, stricture of the urethra, diseased prostate gland, fistula in perineo, blood, worms, calculi or other foreign substances in the neck of the bladder or urethra, pressure of the uterus in the advanced stage of gestation, and displacement of the viscera of the pelvis in the female, pressure of the rectum, tumours, and abscesses in the vicinity of the neck of the bladder, paralysis of the bladder, and, in some instances, from a false passage made by the surgeon. In all of these, there is acute pain in the hypogastric region, particularly when pressed upon, with a constant desire to make water, and accompanied with some degree of a fever. On examining the hypogastric region, the urinary bladder is found distended, and more or less of a pyramidal figure; and on inserting the finger in the rectum in the male, or vagina in the female, a bulbous projection is felt. If the urine is allowed to accumulate, the bladder loses its contractile power, inflames, sloughs, and ultimately ruptures, when the urine escapes into the pelvis, and is extravasated into the contiguous cellular tissue, occasionally upwards to the loins, and downwards to the perineum, scrotum, penis, and upper region of the thighs, either exciting inflammation of the peritoneum and viscera, with a typhoid fever ending fatally, or at once producing coma and death. The kidneys, in the advanced stages of retention are mechanically impeded in the further secretion of urine, by this fluid accumulating in the ureters and pelvis of these organs.

In retention of urine, there is commonly no time to investigate the cause, since the urine must be immediately removed by inserting into the bladder a silver catheter delineated in Fig. 8 of Plate DXV, which is done, either while the patient stands, or lies on his back, by the surgeon grasping the penis with his left hand, while with his right he enters the point of the instrument into the urethra, the handle being over the left groin of the patient; the catheter is then slowly and cautiously conducted along the urethra, bringing its handle to the mesial line, while the penis is at the same time pulled upon it, until the operator considers the point of it in the membranous portion of the canal, when he is to relax the member, and bring forward the handle to a right angle with the body, and ultimately depress it, pressing upwards the point of the catheter with the fore-finger of his left hand in the perineum. If he is foiled in its introduction, he should partially withdraw it, and insert the fore-finger of his left hand in the rectum and press upwards its point as he glides the instrument onwards: this latter attention is especially requisite when diseased prostate gland is the cause, or he may try a smaller-sized instrument. If he is still foiled, he ought to try a flexible gum catheter after the manner of inserting a bougie, which is, to withdraw the stilet, make the patient stand before him, grasp the penis with the left hand, and gently elongate it, so as to make the urethra a straight canal; then insert this catheter cautiously. If these trials fail, and the patient is not suffering severely, he should be bled to fainting, and the introduction of the catheter again attempted; or he may be put first into a warm bath before being bled; and if the catheter does not pass along, a tobacco glyster as directed in hernia may be used: but no violence whatever should be employed in the attempts to insert the catheter, for the surgeon may rest assured that whenever blood flows at the meatus urinarius, he has ruptured the mucous coat of the urethra, is in the corpus spongiosum, or cellular tissue in the vicinity of the membranous portion, and has begun to make a false passage, so that he ought to desist, and puncture the bladder. Male catheters are of different shapes, varying chiefly in their curves. Lieutaud employed a straight catheter, which is now used by Mr. Amussat and others in Paris; a surgeon should have them of different curves, and longer and shorter in the beak, and of smaller and larger diameters. The French, when foiled in the introduction of the common catheter, occasionally use a conically pointed one, which is termed a *sonde conique*, and which they force onwards from the point of resistance in the urethra into the bladder. If the operator succeeds in its introduction, the instrument should be kept in the bladder until all irritation is subdued by antiphlogistic means, when the cause ought to be investigated, and if possible removed. Mr. Amussat, in the Bulletin des Sciences Medicales for October 1825, describes a most ingenious apparatus for relieving retention of urine, by forcing an injection of warm water along the urethra.

The female catheter is delineated in Fig. 10 of Plate DXV. although a male one is equally serviceable, and is inserted while the patient is in bed with her limbs in a bent position, by the right hand of the surgeon holding the instrument, being conducted under the right thigh, when the clitoris is to be felt by the middle finger, and the point of the catheter glided downwards about an inch into the meatus urinarius, and then its handle gently depressed and pushed upwards and backwards around the symphysis pubis. The operator is nearly equally liable to injure the mucous coat of the female urethra, and hence ought to proceed with the same precaution as in the male.

The urinary bladder is punctured at the perineum and per rectum in the male, per vaginam in the female, and above the pubes in both. The operation per rectum is much the simplest and safest, and can be done even in cases of enlarged prostate gland. The patient's nates are brought to the edge of the bed, and his feet placed on chairs widely separated, so that the position nearly resembles that adopted for the lateral operation of lithotomy; the operator then inserts the fore and middle fingers of his left hand oiled into the rectum until he feels the prostate gland, when he conducts along them the trocar and canula delineated in Fig. 11 of plate DXV, sheathed to the space formed by this gland and the fold of the peritoneum named the *cul de sac*, and the vesiculœ seminales, and then plunges the trocar with the canula into the bladder, depressing at the same time its handle, so that the instrument may run parallel with the patient's body; the trocar is next removed, and when the urine has been evacuated, the canula is fixed by tapes run through the hole at its exterior aperture and around the loins and thighs of the patient, this aperture being plugged up with a piece of wood, and the patient afterwards laid in bed, with directions to remove this plug when the bladder feels distended.

After this operation, there may continue such a degree of inflammation or inflammatory fever, as to require active antiphlogistic treatment, and in such an event the canula ought not to be plugged up. The surgeon ought next to investigate the cause, which he is to endeavour to remove; but whatever that may be, he should at the end of 48 hours, by which time suppuration will have ensued, substitute a flexible gum catheter for the silver one, as the latter will excite ulceration of the bladder; a small papilla will direct him, and as the urinary bladder and rectum are intimately united in the healthy state in this space, he can scarcely introduce the instrument between them. When performing this operation on a stout fat man, the operator must expect to experience difficulty in feeling the prostate gland, and reaching the space beyond it. In the female, the bladder is easily punctured from the vagina, the operator calculating the length of the urethra, and if the canula requires to be left, it should be fixed with a T bandage, and care taken that it does not slip into the bladder. The after treatment is the same as that directed in the male.

Stricture of the urethra frequently ensues from gonorrhœa, (described in the article MEDICINE under *Syphilis*, Vol. XIII. p. 30.) and every patient who has been once affected with this complaint, has more or less contraction of the urethra, in consequence of the injury done to the canal, but if left alone to nature the apparent stricture will be removed, while if bougies be used, it will be aggravated. Stricture also arises from stimulating medicines taken internally, from stimulating injections, ulcers in the urinary canal, injury of the urethra, calculus in the bladder, and excess of venery. It has likewise occurred in those who have resided in a warm climate, and in people of a naturally irritable urethra, and so early in life as eleven years of age. It is divided into the spasmodic and permanent, and a combination which is termed the mixed stricture; it occurs in every part of the urinary canal, but most frequently just behind the bulb, which is between six and seven inches from the meatus urinarius; next, anterior to the bulb, or about four and a half inches; thirdly, three and a half inches; fourthly, close to the meatus; occasionally in the prostatic portion; and on some rare occasions, at all these places in one individual. Spasmodic stricture consists in a temporary contraction of the longitudinal fibres of the urethra; permanent stricture, in a greater or smaller contraction of the passage from thickening, which is consequent on an effusion of coagulable lymph, that becomes more and more organized, and ultimately hard and of a white colour. Sometimes this permanent stricture is so narrow or short, as to resemble the constriction made by tying a thread round the urethra, and is named the corded or ring stricture; at other times, only one side of the canal is contracted; while occasionally, cases occur where the whole diameter is contracted for a considerable extent, and this has been termed by some the ribbon stricture. There is always an enlargement of the urethra immediately behind the stricture, considerable thickening of the coats of the urinary bladder, enlargement of the ureters, with affection of the kidneys.

The symptoms of this disease are, inability to expel all the urine at once, there being always a few drops remaining between the stricture and the bladder, so that when the patient imagines he has finished, he finds his clothes wet, and on pressing the penis more urine is expelled; the stream soon becomes wiry, spiral, forked, or scattered, and there is straining with an uneasy feeling in the perineum and anus after voiding the urine; there is a greater desire to make water in the evening and during the night, being seldom able to lie longer than four hours, and occasionally making it involuntarily, with now and then a nocturnal emission. A gleety and even a purulent discharge is present from the beginning, so that it is liable to be mistaken for gonorrhœa. As the disease advances, the urine is voided in drops, great pain is experienced extending to the loins, the urinary bladder is thrown into violent action, and discharges mucus and pus, and the patient elongates the penis. These symptoms, with retention of urine from time to time, either gradually exhaust the patient, or the urethra behind the stricture bursts, and the urine is effused into the cellular substance in the vicinity, as described under retention, or the bladder ruptures, and the same event occurs, or lastly, the urine escapes, and forms fistula in perineo, and the patient survives. The slightest excess in drinking aggravates the symptoms, and often produces the spasmodic stricture, as well as retention of urine; and so also does the change from a warm to a cold atmosphere. These causes, together with the insertion of the bougie, often produce a febrile paroxysm resembling ague. The simple spasmodic stricture is rarely met with in consequence of the patient disregarding it until a permanent state has been induced by the inflammation excited from repeated attacks. When the violence of the spasm is present, the treatment is by bloodletting, a dose of nitrous ether and laudanum, the warm bath, an enema of warm water, or one combined with laudanum, and warm opiate fomentations.

The treatment of the permanent, is by catheters or bougies, the latter of which are made of wax, cat-gut, horse-skin, elastic gum, silver and steel; but the wax, elastic gum, and steel, are those chiefly employed. One of elastic gum or steel, as large as the meatus will admit of, is to be conducted along the urethra down to the seat of the stricture, and the point marked with the nail of the finger, when various ones of smaller dimensions are to be inserted, until one enters the stricture, which if of short extent, or the ring stricture, may be treated with the caustic bougie, which is merely one of wax, having a small portion of the nitrate of silver inserted in the point, and which is to be conducted to the stricture, and kept there with a slight degree of pressure for a few seconds at first, but at each application longer and longer, previously however inserting a common bougie of the ordinary size of the canal for a few seconds, to remove any mucous or spasmodic irritability of the urethra. If the caustic produces so large an eschar as to plug up the urethra, a small common bougie will remove it; and the application of the caustic ought only to be repeated every second day. When there is so great a degree of irritability of the urethra and bladder that the caustic produces a febrile paroxysm, the pure potassa should be used instead of the nitrate of silver, and the warm bath combined, together with the internal exhibition of the muriate of mercury and nitrous ether. The caustic occasionally produces hemorrhage, which may be easily suppressed by compression. The caustic is very liable to make a false passage, especially if the stricture be beyond the bulb of the urethra, and consequently ought never to be employed excepting in this ring stricture. A false passage is to be apprehended if the bougie makes progress towards the bladder, while the difficulty of voiding the urine continues as at first.

In the lengthened stricture, the common or metallic bougie is to be preferred, beginning with one the size of the stricture, and gradually increasing them in size, and retaining them each time for a longer period: indeed, even when a cure is established, the patient should be taught the insertion of an ordinary sized catheter, which he ought to use at least once a week. If irritability follows the employment of this bougie, the same mode of relief is to be adopted as recommended when using the caustic one. The metallic bougie acts by distention, absorption, ulceration, and again absorption. A more expeditious and safe way of curing either the short or long stricture, if the patient will confine himself to bed, is by the insertion into the bladder of a series of elastic gum or silver catheters, beginning with one the size of the stricture, and progressively increasing them. They can generally be enlarged every second day. This is also preferable to Mr. Arnot's method or Mr. Stafford's lancetted stilettes.

The stricture, if of some length, and so small that the bougie cannot overcome it, ought to be cut down upon, and a larger urethra made by the introduction of the flexible gum catheter. A sound is inserted in the urethra down the length of the stricture, and an incision made with a scalpel to its point, when the strictured portion is to be discovered with a probe and laid open, the sound withdrawn and a catheter inserted in the bladder. When the stricture is situated opposite the scrotum, a free incision should be made in the cellular tissue of the latter to prevent the urine from diffusing itself in it. The French use a *sonde conique* and force the obstruction. Mr. Amussat, however, employs the injection of warm water as described under retention of urine. In many instances of strictured urethra, it is advisable to puncture the bladder, and afterwards restore the continuity of the canal.

When the canal ruptures behind the stricture, a free incision should be made to allow the urine to flow by the wound, and the contiguous infiltrated cellular tissue ought to be freely punctured. When the surgeon makes a false passage by the bougie, which is known by the rough feeling communicated to the fingers, by a tearing sensation, and by the instrument being in a degree grasped, he should immediately withdraw it, and desire the patient to retain his urine if possible, that it may not irritate the wound, and diffuse itself in the contiguous cellular tissue, but allow a clot of blood to form, and a slight degree of inflammation to heal the wound. If he persists, either with the bougie or the catheter, he will only aggravate the evil, for the false passage being distended with blood, presses on the urethra, and prevents him from conducting it onwards to the bladder, the urine flows into this passage, is extravasated in the contiguous parts, and forms an abscess which commonly ends in fistula in perineo, or urinary fistula. This disease also ensues from ulceration of the urethra behind a stricture, which is sometimes involved in the ulceration. If there be only an abscess, it ought to be most freely cut open. In this affection, a sound should first be passed into the bladder, and then a flexible gum catheter, which must be worn and progressively enlarged until the fistula is healed. When a stricture has been the cause, either this should be destroyed with caustic or cut down upon, and the latter ought to be preferred. In some rare instances no trace of the original canal can be discovered, in consequence of the urine rendering the substance in the contiguity of the fistulæ (for there is often more than one aperture) purely cartilaginous; and then the operator must make a urethra according to his anatomical knowledge. In the healing of such a wound considerable difficulty is experienced, and may be best accomplished by treating it, as recommended in hare-lip, or by the actual cautery. Stricture of the urethra rarely occurs in the female, and only in consequence of maltreatment in parturition, or in the insertion of the catheter; and when it is present, its treatment is the same as recommended in man.

The prostate gland is very liable to be affected with inflammation in gonorrhœa, and in stricture, and to lay the foundation for more serious disease. In these affections, the symptoms indicative of the prostate gland being inflamed, are an irritable state of the urinary bladder, pain and straining at stool, with tenesmus. An examination per rectum confirms it. Sometimes retention of urine ensues with a throbbing pain in the region of the neck of the bladder, and when the catheter is inserted, great pain is experienced when the instrument arrives at the gland, and is with difficulty passed beyond it into the bladder. The treatment consists in the application of leeches to the perineum or in the anus, enemata of warm water followed by one of laudanum, warm fomentations externally, gentle laxatives, low diet, and rest. General bloodletting is sometimes requisite, and even puncturing the bladder. Abscesses occasionally succeed this inflammatory attack, and the matter is sometimes situated on the exterior aspect of the gland: in general their formation is indicated by rigors, which, however, are not always present, particularly when it takes place in advanced life, from irritability of the bladder. Sometimes the matter is discharged into the urinary bladder, sometimes into the urethra, rectum, and occasionally at the perinæum. Whenever it is ascertained that matter is formed, it should be freely evacuated by an incision; and in those cases where there is not too much irritation it is advisible to insert an elastic gum catheter and retain it in the bladder. Calculi are sometimes secreted in its substance, and require to be removed by an operation similar to the lateral one of lithotomy. Varicose enlargement of its blood-vessels occasionally take place, and are relieved by leeches applied through the medium of the rectum. Medullary sarcoma, fleshy excrescences and scrofulous enlargement, with suppuration, occur; but the chronic scirrhous state is the most common affection of this gland, attacking the male about forty years of age, like that disease in the female mamma about the same period of life. It has been seen in a few rare cases of early life.

The symptoms are, a frequent inclination to make water, which is voided very slowly, in small quantities and with difficulty, and has a strong flavour of ammonia; a dull heavy pain in the region of the gland, which, however, is occasionally sharp and lancinating along the urethra even to the glans, the latter of which, as well as the prepuce, sometimes feels benumbed. He has a difficulty in expelling his feces, which become small, wiry, or flattened; is affected with hemorrhoids and prolapsus ani. When riding in a carriage or on horseback, he passes blood per urethram, and as the disease advances, the urinary bladder becomes affected, and also the urethra and kidneys. On dissection, the gland is indurated, and resembles that described under scirrhus of the mamma; and when much enlarged there projects towards the bladder a portion which resembles a third lobe; sometimes, however, this projection takes place laterally; and in rare instances fungous polypi are attached to its base. The mucous tunic of the urinary bladder, immediately behind the prostate gland, is occasionally forced through the muscular, forming herniary sacs, an event that sometimes occurs in stricture of the urethra, in consequence of the violent straining efforts in expelling the urine. The treatment hitherto has been only considered palliative, which consists in local bloodletting, semicupium, domestic and opiate enemata, and teaching the patient to draw off the urine with the catheter whenever he has a desire to void it, or by his wearing a flexible gum or pewter catheter, which must be changed every ten or fourteen days. The radical treatment consists in removing the gland by an operation, for which the reader is referred to the late Dr. Bruce's Thesis *De Morbis Glandulæ Prostatæ* 1827. In the fungoid condition of the gland, the blood flows into the urinary bladder, and requires to be removed by a silver catheter having a brass syringe adapted to it.

Calculus in the urinary bladder has been already described under *lithiasis* in the article Medicine, so that it remains only for us to detail the resources of surgery, which are the extraction of the stone along the urethra by means of a pair of forceps, with or without dilatation of the urethra; secondly, the breaking down of the calculus in the bladder by means of a lithontripter; and thirdly, by an operation to cut into the bladder and remove the stone. When the calculus is small, it may be extracted by the forceps represented in Fig. 14 or 15 of Plate DXV., or by dilating the urethra by means of flexible gum catheters or metallic bougies, for small calculi are often voided with the urine; but if large, attempts may be made to seize and break it down with the lithontripter represented in Fig. 16 of Plate DXV. which was invented either by Meirieu, Leroy, or Civiale; but the pain attendant on this method is so harassing, and occasionally so severe, that a patient affected with calculus vesicæ will rather submit to the lateral operation. Besides the lateral, there are several other operations of lithotomy; the apparatus minor or cutting on the gripe; the apparatus major; the high or hypogastric; the recto-vesical; the bilateral or Celsian; and lastly, the quadrilateral method. The apparatus major, and the recto-vesical operations may be said to be now abandoned; and the high operation only performed when the calculus is so large that the outlet of the pelvis will not permit its exit. The bilateral is a revival of Celsus or rather Ammonius of Alexandria's method by Beclard and Dupuytren, and differs from the lateral in this, that a lunated incision is made from the tuberosity of the one os ischii to that of the other; and Beclard's differs from Celsus's that he keeps the sound in the urethra until the bladder is freely incised. This is evidently an advisable operation when the calculus is large, and is decidedly to be preferred to the hypogastric. We are confident that this mode, together with Le Cat's teeth forceps or Mr. Earle's stone breaking or screw forceps, will extract the largest calculus that was ever removed in life. This bilateral appears to answer every purpose that the quadrilateral operation, invented the other day by Vidal, can possibly do, and is unquestionably safer and simpler.

The lateral operation is found to succeed best between sixty and sixty-five years of age, next from four to twenty, and most seldom between twenty and sixty. A patient who is to undergo this operation should be free from any flakes of purulent matter in his urine, from diseased prostate gland, from spasmodic action of the abdominal muscles, or any affection of the thorax; he should take a cathartic the day before, have a laxative glyster on the morning of the operation, and the hair of the perineum shaved off. He is then to be secured with tapes on a firm table, with the nates projecting over the margin, and again sounded with a staff delineated in Fig. 3 of Plate DXVI. In ordinary cases of sounding, the patient is not tied up, but is laid horizontally, and if no calculus be found, he should be sounded with a catheter while standing, and when the bladder is full of urine, by which means the stone will strike the point of the instrument; and to facilitate this, the flow of urine may be stopped from time to time. When using the sound, the fore and middle fingers of the left hand of the operator should be inserted in the rectum. A calculus being ascertained to be in the bladder, the staff is to be held firm by an assistant at right angles to the pelvis close under the symphysis pubis, who at the same time supports the scrotum, while two assistants hold the feet and knees of the patient. The operator then makes nearly a perpendicular incision with a scalpel two or three inches longer in its handle (see Fig. 14 of Plate DXVI.) on the left side of the raphe of the perineum, from the root of the scrotum to the fibres of the gluteus maximus muscle which cross the bottom of this wound, and some of which ought to be divided if the operator calculates the stone to be large; this incision is to run midway between the anus and tuber ischii, and should divide the integuments and cellular substance. The operator next deepens this incision opposite the membranous portion of the urethra, carefully avoiding the bulb and the accelerator urinæ and erector penis muscles, but cutting freely the transversus perinæi and levator ani muscles. Having reached the staff, by dividing the membranous portion, he enters the point of the scalpel into its groove, and with his fore and middle fingers depressing the rectum, he runs the scalpel along the groove of the staff through the prostate gland into the bladder (when the urine flows, satisfying him that he has entered the viscus) and cuts obliquely downwards and outwards between the termination of the ulcer and vesicula seminalis, proportioning the incision in the bladder and that of the levator ani muscle to the size of the calculus. The moment he has finished the wound of the bladder and the levator ani muscle, he should insert the fore and middle fingers of his left hand into the bladder over the stone, to prevent its being grasped by the muscular contractility of the viscus; and then pass below his fingers a scoop represented in Fig. 4 of Plate DXVI., and if he cannot easily remove it with this instrument, he should seize it with a pair of forceps, Fig. 5 of Plate DXVI., below the scoop which is to remain in order to prevent the calculus from being removed from its situation, and extract it. If either the bladder, the levator ani muscle, or the external wound is the barrier to its extraction, it should be more freely incised.

Whenever a calculus is extracted, its surface should be examined, and if any part be depressed, it is to be presumed that another calculus is present, which is to be extracted in the same way, but if grasped by the muscular contractility of the bladder, and it cannot be with facility removed, the patient should be unbound and put to bed, for, when suppuration is fully established, which is commonly the third day, it may be done without giving the patient the least pain, by simply inserting the fore and middle fingers of the left hand into the wound. But if not, the scoop may be again used, or the forceps, if the operator prefer them, and even a sound may be inserted along the urethra without exciting pain. This mode is termed *operation en deux tems*, and may even be employed with advantage, if any difficulty exists in extracting the first, or even when only one calculus is present. If a calculus is soft, and breaks in extraction, the bladder should be carefully washed out with warm water injected by means of a syringe.

When the operation is finished, the patient should be unbound, and put to bed, with a piece of oiled lint applied to the wound, and a bottle of hot water to his feet; and, whenever reaction has taken place, he ought to be bled, if he has not lost much blood during the operation, and in both cases, if there be the slightest appearance of peritoneal inflammation, which, if it follows, must be most promptly treated with antiphlogistic remedies. If hemorrhage supervenes, it is to be checked with a piece of dry sponge inserted in the wound, having a female catheter pushed through its centre to allow the urine to flow. If the blood flows into the bladder, it excites spasms, and must be washed out with tepid water. Low diet, with gentle laxatives for eight or ten days, ought to be prescribed. In general the urine begins to flow along the urethra about the twentieth day, and the patient is well in four or five weeks.

When calculi are encysted in the bladder, unless at its neck, they produce no irritation; and when situated there, they require to be removed by the same operation. Occasionally, calculi have been found in the bladder at death, in those who have never complained of them during life; and individuals have passed the greater portion of their lives with a calculus in their bladder, until a certain exertion has called into action all the horrible sufferings attendant on this complaint. In this lateral operation, there have been a great many deviations, and a great number of instruments invented, from the time of Ammonius of Alexandria to the present day; indeed, it may be said, "that every surgeon performs this operation after his own fashion, the same manner as he signs his name."

Cutting on the gripe, invented by Fabricius Hildanus, and practised in the present day on boys, consists in inserting a staff or sound into the bladder, then the fore and middle fingers of the left hand in the rectum, and bringing forwards the calculus to the perineum, when an incision is made on the left side of the raphe in the perineum as in the lateral operation, at once upon the stone, which is extracted with the fingers of the right hand or a hook.

When calculus occurs in the female, it may be removed by dilating the urethra with Weiss's forceps; but unless the stone is small, this is a cruel method, and often causes the patient to be tormented with incontinence of urine for life. An operation is, therefore, to be preferred, and that per vaginum, as done by Fabricius Hildanus, Ruysch, Tolet, Klein, and Vacca, appears superior to those of Messrs. Louis, Dubois, and Lisfranc.

When small calculi are arrested in the male urethra, they are stopt either at the perineum, opposite the scrotum, or opposite the frenum. When at the perineum, a large sound is cautiously inserted into the urethra, until it touches the calculus, the penis and sound are then tied with a piece of tape, and the patient desired to drink freely of diluents; and when the urine has accumulated in the bladder, the tape and sound should be removed, that he may make water forcibly. If this does not succeed, an incision should be made over the stone and extracted. When opposite the scrotum it is highly dangerous, and an attempt must be made to push the calculus gently backwards to the perineum, and treated as just recommended; but if this is impossible, a free incision must be made through the scrotum over the calculus and extracted. When opposite the frenum, it may be removed by inserting a common silver probe, with its eyed-end bent for a short distance; but if this does not succeed, it must be extracted by an incision.

There are a few surgical operations appertaining to gonorrhœa and syphilis, which require to be adverted to. In both of these diseases, phymosis, which is a swollen condition of the prepuce, with inability to denude the glans penis, frequently occurs, and when it takes place in syphilis, and the surgeon suspects chancres beneath it, it ought to be cut up, by inserting the curved sharp-pointed bistoury, with a button of wax, between the prepuce and glans, until its point reach the angle of reflection between them, when the operator, retracting the skin, pushes the point of the bistoury through the prepuce in the mesial line, and opposite the frenum, or by the side of the frenum, and cuts at once outwards. The two sides should be stitched individually, to accelerate their healing. A contracted state of the free margin of the prepuce is a frequent congenital affection, and should always be divided, so that the individual may be able to denude the glans; for, as Mr. Roux observes, such a condition predisposes to cancer of the penis.

Paraphymosis is a contracted condition of the prepuce behind the glans, preventing the latter from being covered, and frequently happens to boys in their innocent gambols. In this affection, the glans becomes tumefied, and both it and the prepuce are infiltrated with serum, sometimes giving a peculiar twisted shape and appearance to the organ. If recent, it may be reduced; and, in general, a few punctures of the lancet, followed by fomentations or poultices, subdue the swelling, and allow the prepuce to be brought forward; but in some cases it is requisite to divide the strictured integuments and mucous membrane of the prepuce with a bistoury. Abscesses sometimes occur in the lacunæ of the urethra, which require to be freely opened from without, otherwise they are liable to produce retention of urine, fistula in perineo et ano, and if into the scrotum, they prove fatal. When a chancre affects the frenum præputii, the latter should be divided with a bistoury.

The prepuce, glans, and even the body of the penis sometimes become indurated, and the glans ultimately cancerous or fungous, either spontaneously or in consequence of repeated attacks of syphilis, and sometimes from neglected warty excrescences. The discharge in such cases is extremely fetid and sanious. If the remedies recommended under syphilis fail to cure it, the diseased portion ought to be removed by laying hold of the penis, and cutting it off at once, at a healthy portion of the member; then instantly inserting a flexible catheter in the urethra, securing the arteries, approximating the edges of the wound, from above downwards with suture and adhesive plaster, but leaving the catheter free. The wound to be dressed on the third or fourth day.

The testis is extremely liable to be affected in gonorrhœa, and when inflamed, swollen, and painful, it is termed hernia humoralis: and is treated by antiphlogistic remedies, with the injection of warm water into the urethra, to reproduce the discharge which is ordinarily checked, or to mitigate the irritation of the canal, the source of the disease of the testis. If the patient cannot procure leeches, he should immerse the scrotum in warm water, or stand before a fire until the veins become turgid, when they should be lanced in several points, and the scrotum again immersed in warm water; the patient standing all the time, for whenever he sits the bleeding ceases. After the activity of the inflammation has been subdued, and if the swelling remains, the scrotum should be fumigated with mercury, or anointed with mercurial ointment, having ultimately camphor mixed with it. In some cases an alterative course of mercury, with sarsaparilla, is requisite, with a succession of blisters, and the insertion of the bougie into the urethra, and the patient ought to be confined to the horizontal position for a considerable period. The testis sometimes suppurates, and should then be freely opened, as recommended under acute and mammary abscesses. Occasionally a fungus shoots forth, which requires to be removed either with the knife or the caustic. At other times wasting, or a total disappearance of one or even both testes occasionally takes place, and generally occurs between 14 and 20 years of age; and sometimes from the most simple accidental causes.

The different species of sarcomy, and the theory of their formation, have been described under diseases of the mamma; and the medullary, and carcinomatous of the testis, in no respect differ from these affections of the mamma, either in character or treatment. The medullary very soon contaminates the spermatic cord and lymphatic glands in the region of the kidney, the latter appearing in the form of a tumour in the short space of a few weeks, so that unless castration be performed very early in this species of sarcoma, it soon becomes incurable. It attacks the constitution so early as four years of age, but more commonly between fifteen and thirty-five.

If the antiphlogistic treatment, and other means mentioned under hernia humoralis fail in curing the carcinomatous, and the spermatic cord is free from pain, castration should be performed in the following manner:—An incision is made from the external aperture of the inguinal canal along the cord to the inferior point of the scrotum, through the skin and cellular substance; the cord is then insulated, and grasped by the fingers of an assistant, and divided between the fingers and the testis, the latter of which is to be dissected out, cutting first on the mesial aspect, to preserve the mediastinum scroti. The arteries of the scrotum are next to be instantly secured, and then those of the spermatic cord; the sides of the wound approximated with sutures and adhesive plaster, and a piece of charpie and two silk handkerchiefs, or a T bandage applied. If there is any diseased skin, two semi-elliptical incisions are to be made on each side of it, that it may be removed along with the testis; and since hemorrhage from the arteries of the scrotum is exceedingly liable to follow, an assistant ought to be appointed to observe their situation during the operation.

If hemorrhage ensues and fills the scrotum, the affection is termed hæmatocele, and is to be treated by styptics; and if these fail, the wound must be exposed, and the arteries secured, but they are commonly so small as to be scarcely visible, the wound therefore must be stuffed with dry lint or sponge, and afterwards stitched. The common vascular or organized sarcoma, or sarcocele also requires castration, and in this species the cord is commonly thicker, which however is no obstacle to the operation. In the advanced stage of sarcocele, cancer, and fungus hæmatodes, a fungus excrescence sometimes originates from the body of the gland; and a similar growth, in some instances, arises from the tunica albuginea, or even the body of the testis, in consequence of hernia humoralis, or an enlargement from a bruise. A small abscess occasionally appears, which bursts, and a fungus is protruded, that is named lipoma. In all of these the excrescence should be removed with the knife, and nitrate of copper or potassa afterwards applied. A chronic enlargement of the testis sometimes occurs in gonorrhœa, stricture, and syphilis, which is to be treated as recommended under hernia humoralis. At other times, this chronic enlargement is not dependent on these affections, but upon scrofula, and acquires, on some occasions, a prodigious magnitude, ultimately involving the other testis and the scrotum, and cured by no other remedy but castration.

A peculiar irritable condition of the gland not unfrequently presents itself, resembling neuralgia; which is to be treated with rest, warm bath, and the mecurial pill, combined with hyosciamus; and if these fail, by castration. A neuralgic affection of the external spermatic nerve occasionally occurs, which is to be treated as recommended under that disease of the face. Sarcocele is frequently accompanied with hydrocele, and then termed hydrosarcocele, in which case it will become a matter of consideration, whether the hydrocele ought not first to be cured, and then an attempt made to cure the affection of the testis, by the means recommended for hernia humoralis. This will chiefly depend on the magnitude of the gland; and hence, in all complicated cases, a trocar and canula should be plunged into the tumour, to ascertain whether fluid does not chiefly constitute the bulk of it.

Hydrocele is also occasionally complicated with hernia and circolele. In simple hydrocele, the serous fluid is effused between the tunica vaginalis, and tunica albuginea, and gradually as it collects, the testis ascends, and occupies the middle and back part of the tumour, while the fluid rises by the side of the gland and cord, upwards to the inguinal region, and hence is liable to be mistaken for hernia, diseased testis, circocele, and anasarca of this part. Hydrocele is distinguished from these affections by its pyramidal figure, elasticity, transparency when examined by a candle, by the deficiency of swollen cutaneous veins, and the history of the case. The fluid is generally serous, of a pale straw colour, but sometimes greenish, at other times dark, turbid and bloody, while occasionally it is of a violet colour. When the disease has existed long, cartilaginous bodies are found in it, and the tunica vaginalis becomes thickened. In some instances, adhesions exists either between the middle, the sides, or the bottom of the testis and the tunica vaginalis.

The treatment of hydrocele is palliative and radical; the former consists in simply drawing off the fluid with a trocar and canula of steel, as represented in Fig. 9 of Plate DXV, which are to be plunged into the tumour, a little below its middle, and where no veins are present, first at right angles until the operator feels he has entered the tunica vaginalis, and them sloped obliquely upwards nearly parallel with the integuments; the operator during this grasping gently the tumour and the testis with his left hand, in order to remove the latter from the trocar, which is then to be withdrawn; and after the removal of the fluid, the canula also. A piece of adhesive plaster, a compress of lint, and a T bandage are to be applied. This palliative operation is performed to remove the fluid when the testis is diseased, in order that all pressure may be removed; and afterwards, an alterative course of mercury with sarsaparilla, a succession of blisters or mustard cataplasms, or friction with the ointment of iodine, and the insertion of the bougie if necessary. It is also performed to ascertain the condition of the gland.

The radical treatment consists in incision, excision, caustic, tent, seton, and injection, the last of which is now only employed. A kind of tent, however, made of a piece of elastic gum catheter is employed by Baron Larrey; the seton by Sir A. Cooper in children; and excision in a modified way by Mr. K. Wood. Injection is merely re-distending the vaginal sac, after the evacuation of the serous fluid, with cold water, port wine, a solution of the muriate of mercury in lime water, spirit of wine, a solution of the sulphate of zinc in water, in order to excite such a degree of inflammation, as to cause adhesion between the tunica vaginalis and albuginea, which is accomplished with the greatest safety and equal certainty by the cold water; for if injected at the temperature of 32° of Fahrenheit, it will produce, instead of the adhesive inflammation, mortification; and if diffused in the contiguous cellular tissue at a more moderate temperature, it will prove less stimulating than any of the other fluids. In this operation, therefore, whenever the serous fluid has been evacuated, the canula is to be allowed to remain, and into it is to be inserted the pipe of a common brass stopcock having affixed to it an ox's bladder, filled with cold spring water, see Fig. 23 of Plate DXV. The cold water ought to excite pain in the testis, spermatic cord, and loins, which it commonly does in ten or fifteen minutes; but if not, a fresh quantity should be injected, or some at a lower degree of temperature. If the water by accident is diffused in the cellular tissue of the scrotum, it should be evacuated by punctures with the lancet.

If hemorrhage takes place in the tunica vaginalis producing hæmatocele, this tunic is to be laid open, according to circumstances, the blood removed, and its further effusion checked by the application of cold water, or some other styptic, or lint. After this operation, the patient is to be treated antiphlogistically, or allowed to walk about, according to the inflammation induced; and when this action subsides, the scrotum should be annointed or fumigated. If this operation fails, it ought to be repeated in the course of two or three months. Encysted dropsy of the spermatic cord occasionally occurs, particularly in children, and is to be treated like hydrocele.

Circocele, or varicocele of the spermatic cord, is a varicose enlargement of the veins of the cord, occasionally extending to those of the testis and scrotum, and sometimes present on both sides, which either presses on the gland, and removes it by absorption, or produces ulceration. It has a knotted or vermiform appearance, and is easily distinguished from the preceding diseases. The mode of treatment is confining the patient as much as possible to the horizontal position, suspension of the parts with a suspensory truss, the application of cold water, or oak bark decoction twice or thrice a day, and keeping the bowels gently open.

Chimney sweeper's cancer, or soot-wart, is a peculiar cancerous ulceration of the scrotum, which spreads to the clefts between the latter and the thighs, and ultimately involves the testis, the lymphatic glands in the groins, the spermatic cords, and the viscera of the abdomen, and proves fatal. The ulceration is divided into rugæ, is of a red colour, and the discharge extremely nauseous and fetid, even the perspiration of the whole body has a rank ammoniacal smell. This ulceration generally occurs between twenty and forty years of age, although it has appeared so early in life as eight, and attacks chimney sweepers, shoemakers, and smelters of ores which contain arsenic, and all classes of workmen who are uncleanly in their persons. The treatment is the same as that recommended for *noli me tangere*, and the other herpetic ulcers; and if this fails, by the knife.

Some of the diseases of the female organs have been already described in the present article, and others under Medicine and Midwifery. One or both of the external labia are sometimes so injured in parturition by a blow, that ecchymosis takes place to such an extent as to produce retention of urine by closing the meatus urinarius. This is to be treated by leeches, warm fomentations or poultices, and drawing off the urine by the catheter. Sometimes they suppurate and even mortify, the treatment of which is described under acute abscess and mortification. Laceration of the labium or perineum is sometimes to such an extent, and produces so much hemorrhage as to require compression with lint, or dry sponge and a bandage. The labia, particularly in children, are often attacked with inflammation that runs on to phagedena gangrenosa; and in milder attacks, or even in excoriation, they sometimes adhere, and shut up the passage, which requires to be opened with the scalpel, that the urine may be voided.

Children from one year old to puberty are frequently the subject of a purulent discharge from the pudendum, that originates chiefly beneath the præputium clitoridis, the nymphæ, the orifice of the vagina, and the meatus urinarius, all of which are inflamed: and this disease has been mistaken for the injury done to these parts in a rape, and men, says Sir A. Cooper, have been executed on the evidence of an ignorant surgeon. The treatment is the same as that recommended for acute inflammation of a mucous membrane.

Imperforated congenital vagina is far from being uncommon, and there is generally a mark or raphe indicative of its situation; sometimes it is deficient, at others the whole of the middle portion of the canal is filled up with solid matter; and in other instances again a firm septum is stretched across behind or deeper than the hymen. An incision should be made from above downwards, carefully guarding against wounding the meatus urinarius, and preserving enough to correspond with the perineum; and preventing a reunion by oiled lint. In some instances there is a small aperture superiorly into which a probe or bistoury can be inserted, and the part divided.

Imperforated hymen is fully more common than that of the vagina, but is seldom discovered until the catamenia have been secreted, when great pain is produced by the distention of the uterus and vagina; and a tumour becomes perceptible above the pubes. A transverse division of it with the bistoury gives free exit to the catamenia and relieves the patient, but attention must be paid to the effects of their retention, for frequently considerable inflammation is excited, which requires active antiphlogistic treatment, with injections of warm water per vaginam. To prevent the membrane from reuniting, a rectum bougie should be inserted, either daily or every second day. In the division of the hymen the operator must guard against wounding the meatus urinarius. This membrane has been also found so rigid, as to require a similar incision. In some cases, there is great confusion of the genital parts, the vagina communicating with the urethra, the rectum terminating in the vagina, a double vagina, and even two uteri. There are also cases of the uterus being deficient.

Various species of tumours grow from the labia, nymphæ and orifice of the uretha, requiring to be removed by the knife. The nymphæ become sometimes so pendulous as to require partial removal; and the clitoris so large, that when a congenital protrusion of the ovaria at the inguinal canals is combined, the sex is mistaken, or the individual is pronounced a hermaphrodite; it is also occasionally affected with cancer, and, in either case, requires amputation. In these little operations, there is commonly so considerable a degree of hemorrhage as to require the ligature or actual cautery. The clitoris, likewise, requires to be removed in nymphomania. In ascites and dropsy of the ovarium, the fluid occasionally gravitates between the vagina and rectum.

The uterus is subject to acute inflammation from cold, which often becomes chronic, although this latter stage sometimes begins *à priori*, and leads to dropsy, ulceration, scirrhus, cancer, ossification, atheroma, steatoma, medullary sarcoma, tubercles, polypus, moles, and hydatids: calculi, vermes, and air have been generated in the uterus. The acute is easily distinguished, and is to be treated antiphlogistically; the chronic is peculiar in this, that the patient often feels pain near the liver, and after it has continued for any time, a discharge of mucus which becomes occasionally purulent and mixed with blood, takes place: there is sometimes uterine hemorrhage, and the patient has an exsanguineous countenance. On examination, the os tincæ is larger than natural, soft, and tender; and, in the hypogastric region the uterus feels swollen, and is painful to the touch. The palliative treatment in this and the other diseases is by cupping or leeches, to the pubes and groins, anodyne enemata, and injections, per vaginam, extract of hemlock inserted in the vagina, gentle laxatives, low diet, and confinement to the horizontal position, and the administration of ergot internally. The radical, by extirpation of the organ, as lately done with success by that profound scientific accoucheur, Dr. Blundel of Guy's Hospital. The uterus has been extirpated by Carpus, Laumonier, Osiander, Langenbeck, Sauter, Siebold, Holscher, Wolff, Recamier, and Lizars.

There is a peculiar ulcer described by Dr. Clark, termed the corroding ulcer of the womb, and by Mr. Burns, phagedenic ulcer, which should also be treated by excision, as practiced by Lisfranc, or extirpation, by Dr. Blundel. There is another species of ulceration attacking the os and cervix uteri, described by systematic writers, which, however, is merely a modification of the preceding, and should be treated in the same manner. Firm and cauliflower excrescences frequently grow from the os uteri, which should be excised. Polypous excrescences from this region may be removed either with the ligature and double canula, or the knife.

The ovarium is subject to acute and chronic inflammation, to dropsy where the fluid is contained in one or more cysts, to dropsy combined with various degenerations of texture, and morbid productions, viz. collections of hydatids, scirrhus, ossification, calculi, steatoma, sarcoma, atheroma, melliceris, hair, bones, and teeth. The ovaries, as also the fallopian tubes, are subject to congenital malformation. These tumours grow sometimes to an enormous size, and are then frequently complicated with ascites, or adhesions to the abdominal parietes and viscera, when hydatids also originate from the latter. In the first stage, their pedicles are very small, and they can be removed from the one side of the abdomen to the other, and are then favorable for an operation, which is performed as recommended for ileus. When the abdomen is freely laid open (the temperature of the room being at 80° Fah.) the viscera are to be encircled in a towel that had been previously immersed in warm water at 98°, the tumour held by an assistant, its pedicle secured with a ligature, both ends of which, as also the tumour, are to be cut off. If the disease be complicated with ascites, the case is still more favourable. If extensive adhesions are present, an incision through the abdominal parietes should be made, and if these are found to exist between the tumour and the anterior parietes of the abdomen, a seton ought to be inserted across the abdomen and tumour, care being taken not to wound the epigastric arteries. For further information on this subject the reader is referred to Lizars *on Extraction of the Ovarium.*

It is chiefly in the female constitution that violent or excessive hemorrhages occur exhausting life, which is reanimated by the process termed transfusion, for the revival of which the public is indebted to Dr. Blundell, who has now performed it repeatedly with success. The best apparatus is that invented by Reid, which is delineated in Fig. 13 of Plate DXV. A vein of the arm of a healthy person should be opened, as in phlebotomy, and the blood received into the cup *a*, from which the tube *b* conducts it to the bottom of the syringe *c*, whence it is propelled along the tube *d*, into the small pipe *e*, inserted in the vein of the expiring patient.

The diseases of the rectum are piles, tubercles, sarcomatous tumours, and ulceration; stricture of the rectum, abscess near the anus, fistula in ano, prolapsus ani, and imperforate anus. Piles, or hemorrhoids, arise from constipated bowels, pressing and impeding the circulation of the hemorrhoidal veins, or from relaxation of the bowels, produced by diarrhœa while these veins are not sufficiently supported, or from one or other of these causes, especially the first occurring in pregnancy; and hence pregnant women are most subject to them, for the pressure of the uterus becomes also a cause. They are small purple coloured tumours situated around the anus, consisting either in a distended thickened varicose state, or rupture of these veins, the blood, in the latter case, being most frequently diffused in the cellular tissue around them. Piles are divided into external, internal, blind, and open. The external are situated outside of the anus, the internal within the rectum; the blind are such as do not bleed, while the open bleed.

Piles are a most troublesome complaint, preventing the patient from either walking or even sitting with comfort, since he is only easy in a horizontal attitude; and not unfrequently the pain is most excruciating, particularly on going to stool, when they sometimes bleed to such an extent as to debilitate the individual, and give to his countenance the peculiar exsanguineous aspect. The great Copernicus bled to death from this disease. The treatment consists in removing the cause, which, when constipation, by mild laxatives, and in laying them open with a lancet or bistoury, or applying leeches to them, and afterwards by fomentations or poultices. After the inflammation has been subdued, by the application of the ointment of gall nuts, or a decoction of oak bark. When piles are lanced, care should be taken that hemorrhage does not flow internally in the rectum, for patients have thus bled to death. Sponge is the best suppressor of bleeding in this part. When neither pregnancy nor diarrhœa is the exciting cause, an alterative course of mercury is beneficial; but the last mentioned disease must be checked by astringents. A rectum bougie or tallow candle is an excellent discutient, which should be inserted at bed time, and allowed to remain during the night, care being taken that it is properly fastened to a belt round the loins, and that the hemorrhoids are reduced within the anus. All kinds of constipating stimulant food ought to be abstained from, and the patient should avoid exercise, and sit on a hard chair. When piles are large and pendulous, they ought to be removed with the knife; ligatures should never be applied, as they have produced symptoms of strangulated hernia and tetanus.

Tubercles of the rectum frequently follow hemorrhoids or constipation, and consist of an indurated state of the solitary glands of this intestine; the mucous tunic being arranged into irregular hard folds, and the muscular subdivided by membranous septa, the whole wall of the gut being much thickened and hardened, and this condition of the rectum is seldom discovered before it has assumed the carcinomatous action. The patient is troubled with irregularity of his stomach and bowels, with vomiting, cholic, diarrhœa, and dysentery. The disease next forms a stricture, and often extends to the colon, when more than one of these constrictions is present; in this case, there is greater irregularity of the bowels, for the patient occasionally has no motion for days, which either passes in the form of an earth worm, or is liquid from medicine, and he experiences considerable pain and straining at stool. The tubercles next become malignant and ulcerate, when his sufferings are generally truly deplorable. There is a voracious appetite, a constant vomiting, and a burning pain in the stomach and over the whole abdomen, with lancinating burning pains of the rectum and anus; together with hectic fever, and an inclination to go to stool every moment. This ulceration of the rectum occasionally extends to the urinary bladder, forming a communication between them, when sometimes the fœces flow into the bladder, and at other periods the urine into the rectum, and on some occasions they flow promiscuously into each other; and towards the end of the flow of the urine, air gurgles along the urethra, producing a loud and unpleasant sound: on rare occasions there is little or no pain. In some cases, a total obstruction to the passage of the feces along the colon takes place, when this intestine acquires so prodigious a magnitude as to deceive us for ascites. In other cases, the ulceration is fungoid, bleeding and discharging a great quantity of pus at every evacuation of the feces, with little or no pain.

In the first stage of the disease, the patient should be confined to bed, take gentle laxatives, apply leeches within the anus, have laxative and opiate enemata administered with the warm hip bath once or twice a-day; and his diet should be purely farinaceous. And if by this treatment no amelioration is produced, and the diseased part can be reached by the knife, it should be extirpated, as lately done by Lisfranc. If the pain can be subdued, the rectum bougie ought to be used, and may be anointed with an ointment of opium, hyoscíamus, or hemlock: and where a short stricture exists, it ought to be divided in the four diagonal directions with the bistoury. Generally all kinds of external applications produce pain, even warm oil. If the patient can be removed to a warm climate, he ought instantly to go, and if not, the same soothing means must be continued until the disease either subsides or proves fatal. The compound powder of ipecacuan in small doses is an excellent anodyne in this disease.

Abscesses very often occur near the anus, in consequence of the loose delicate cellular and adipose tissues in this region, and when permitted to burst of their own accord, generally rupture with a small aperture, become fistulous, and occasionally burrow towards the rectum, and even form a communication with it. They arise from constipation and hemorrhoids; also from fish bones, &c. which have been swallowed and arrested in the rectum; from bougies breaking, pieces of wood, and other foreign bodies slipping up the rectum. For the treatment of this, the reader is referred to acute abscess. When this becomes fistulous, the disease is termed a blind external fistula in ano, and should be freely laid open with the curved sharp-pointed bistoury, having a button of wax upon it, and afterwards treated as directed under acute abscess. All fistulous tubes are more or less callous. Sometimes this fistula burrows along the rectum for a considerable extent, having many digressions in its course in the natis, so that considerable difficulty is occasionally experienced in arriving at its source; and when the surgeon has inserted the bistoury into what he conceives the root of the fistula, and pushed the instrument through the walls of the rectum, and cut outwards so as to make them one tube, he has probably by no means reached the termination of the fistula. In such cases, the daily insertion of sponge tent, making it larger at each introduction, will so expand the sinus or fistula, as to enable the operator to explore all its circuitous routes. If the matter runs into the rectum, and there is no external aperture, the affection is named a blind internal fistula, a variety which seldom or ever exists, but when it does, ought to be laid freely open.

When the fistulous tube opens both externally and into the rectum, which is the most common variety, it is styled complete fistula in ano, and is ascertained by inserting a probe into the fistula while the fore-finger of the left hand is in the rectum. It is treated by inserting a probe-pointed bistoury into the fistula onwards into the rectum, and cutting freely downwards and outwards, so as to convert the fistula and rectum into one tube. The after treatment ought to be the same as described under acute abscess. The patient, after having motion in his bowels, should be careful to wash the surface clean with tepid water or a syringe. When fistula in ano occurs in a phthysical constitution, it is a question whether or not it should be cured, because it acts as a counter-irritant, or on the principle of counter revulsion, according to the doctrine of the ancients. Ligatures are used in France, but never in this country.

Prolapsus ani consists in an eversion of the rectum, consequent either on relaxation or irritation, and occurs in children affected with ascarides or calculus in the urinary bladder, in adults from gestation, hemorrhoids, constipation, dysentery, diarrhœa, and drastic purges; and in old people more frequently than in those of the meridian of life. On some rare occasions, the prolapsed gut has become gangrenous and sloughed off. The prolapsus is to be returned by making the patient stand on his feet, with his head dependant or resting on a chair, and then taking a piece of fine soft linen, and pushing gently and gradually. When reduced, a recurrence is to be prevented by remaining in bed for some time, or wearing a steel spring, delineated in Fig. 7 of plate DXV. by removing the cause if possible, and by injecting a strong decoction of oak bark. Sometimes it is necessary to foment the gut with warm water, or even to scarify or leech it before attempting reduction. Sponge has been inserted in the anus to prevent a recurrence, and pessaries have been worn; and the late Mr. Hey, Langenbeck, and Dupuytren, treat it by raising with the forceps or a ligature the skin around the anus, and removing this with curved scissors. A circular portion of the mucous tunic of the intestine has been also removed.

Imperforate anus is a congenital malformation, and hence all children should be carefully examined when born. Sometimes the rectum is perfect onwards to the integuments which are entire, and have a raphe and every indication of a perfect anus; at other times, there is a distinct external aperture or anus, but the rectum is closed by a *cul-de-sac* a little within or centrad; at others again there is no external aperture, but a communication with the vagina in the female, and with the urethra or urinary bladder in the male. In the female, the aperture of communication is occasionally exceedingly small, while in others it is tolerably large; in the male, the rectum commonly ceases at the promontory of the sacrum, where it forms a puckered purse-like pouch, which either communicates with the bladder by a valvular opening, or descends in a small tubular form, adhering to the bladder, and enters the membranous portion of the urethra in the same valvular manner. The last variety occurs where there is no communication with the bladder or urethra in the male, or with the uterus or vagina in the female, and no external aperture.

In the first of these cases, where the rectum is close to the integuments, a simple incision with a scalpel, will allow the meconium to be evacuated; but care should be taken that the bougie or wax candle is inserted daily until all tendency to contract is removed. Some authors recommend that this operation should be done between twenty-four and sixty hours after birth, but in our opinion the sooner nature is relieved the better, as respiration is much impeded until the evacuation of the meconium takes place, and inflammation not unfrequently ensues from delay, which is to be subdued by a leech or two applied to the hypogastric region and the warm bath, together with castor oil. Before making an incision in such cases, the skin should be titillated, which causes the child to make efforts to evacuate the feces, and produces a protrusion where the anus is to be made. A trocar and canula is recommended to be used for perforating the integuments and even the rectum in the other cases, but it is a dangerous instrument. Instead of the bougie or candle, sponge and sponge tent are used by some, but these, since they excite ulceration, ought not to be employed.

In the second variety, or where there is an anus, but the rectum has formed a *cul-de-sac*, the latter is to be opened with a narrow shaped scalpel. In that variety occurring in the female, where there is a communication with the vagina, characterized by the meconium discharged by this passage and in that of the male where it takes place with the urinary bladder or urethra, the meconium is discharged mixed with the urine; and in the last variety where none of these characters exist, the operator must divide the integuments with a narrow-shaped scalpel perpendicularly to the extent of an inch or so, sufficient to admit his forefinger where an anus should be, and which is generally distinguished by some puckering or indentation of the skin. He must next dissect carefully along the concave aspect of the os sacrum, leaving it sufficiently clothed with cellular substance, until he feels a small distended pouch, which he may rest assured is the rectum filled with feces, and forced down by the action of the diaphragm and abdominal muscles; this he is to puncture with the same scalpel, and not with a trocar and canula, when the meconium will flow by the side of his finger. After this operation, a tea spoonful of castor oil should be given, and the child immersed in a warm bath, and if there appear the slightest enteritic or peritoneal inflammation, one or more leeches must be applied to the hypogastric region. The after treatment is the same in this as in the first variety. Mr. Burns directs us, if no rectum can be found, to open the sigmoid flexure of the colon, and Mr. C. Hutchinson the caput cæcum coli; but neither we apprehend will ever be required, and of the two we should prefer the former, which we may observe has been done. Callissen recommends the colon to be opened in the dorsal region near the left quadratus lumborum muscle, while Mr. Burns more judiciously between the anterior and posterior superior spinous processes of the left os ilium; the gut to be opened where it is uncovered by the peritoneum, a direction difficult to be fulfilled, as it is loosely bound down by the mesocolon. In the Revue Medicale for December 1823, there is an extraordinary case detailed of a man who arrived at the age of seventy years and who was born with an imperforate anus and urethra, and who vomited his excrements during all that time. He was alive five years ago.

DESCRIPTION OF THE PLATES.

PLATE DXV.

Fig. 1. Scarificator, consisting of a brass box of twelve lancets, six of which move on two rollers in opposite directions through the medium of a lever *b*. When the lancets are moved round and hid, they are said to be set; and when applied to the skin, they are fired off by compressing the spring *c*. See page 527.

Fig. 2. A common bistoury five inches long in the blade, the point of which is double edged for a short distance. See page 535.

Fig. 3. A moxa-holder or *port-feu*. See page 531.

Fig. 4. An eighteen-tailed bandage, which may consist either of calico or flannel; *a*, is a longitudinal piece to which the other cross ones *b*, are stitched. See page 530.

Fig. 5. An aneurismal needle. See page 546.

Fig. 6. M'Intyre's fracture-splint improved by Mr. James Fortune. *a*, a joint between the thigh board *b*, and the leg board *c*, moved by a screw, so as to alter the angle at pleasure. *d*, a screw attached to the board *e*, in order to lengthen it. *f*, a foot-board moved by the screw *g*. See page 550.

Fig. 7. Bandage for prolapsus ani. &c. *a*, the belt which surrounds the loins; *b*, the pad which supports the protrusion. See page 596.

Fig. 8. A male catheter, to draw off the urine. See page 586.

Fig. 9. A trocar and canula employed in dropsy. *a*, the trocar, *b*, the canula. See page 581.

Fig. 10. A female catheter. See page 587.

Fig. 11. A trocar and canula for puncturing the urinary bladder. *a*, the trocar, *b*, the canula. See page 587.

Fig. 12. The stomach-pump. *a*, the tube inserted in the stomach; *b*, the syringe; *c*, the gag; *d*, a tube to carry the fluid into a basin. See page 582.

Fig. 13. Transfusion apparatus. *a*, a cup to receive the blood from a person in health; *b*, a tube which conducts it to the syringe *c*; *d*, a tube which conducts the blood from syringe *c*, to silver pipe *e*, that is inserted in vein of expiring patient. See page 595.

Fig. 14. Forceps to extract calculi from the urinary bladder. *a*, a silver canula; *b b b*, three prongs capable of being opened or shut by the spring *c*, together with the handle of the instrument. See page 590.

Fig. 15. A two-pronged forceps for the same purpose as Fig. 14. See page 590.

Fig. 16. Civiale's lithontripter, that consists of a canula *a*, in which is concealed a three-pronged forceps *b b b*, together with a drill *c*. The drill and forceps are represented in Fig. 24, concealed as they are introduced along the urethra; while in Fig. 16, they are expanded as if in the urinary bladder. The instrument is held firm by an assistant, and the operator, by means of the handle *d*, while the latter works the drill *c*, by a common drill-bow having the catgut string round the wheel *e*. See page 590.

Fig. 17. A trephine. *a*, the crown or saw. *b*, the centre-pin which is extended or retracted by means of the button *c*. See page 564.

Fig. 18. An elevator used when trepanning the skull. See page 564.

Fig. 19. Hey's saw, employed in depressed cranium. See page 566.

Fig. 20. Cataract knife. See page 572.

Fig. 21. Dissecting forceps. See page 546.

Fig. 22. Cataract needle. See page 569.

Fig. 23. Bladder, with stop-cock for hydrocele. See page 593.

Fig. 24. See Fig. 16. and page 590.

Fig. 2. Amputating knife. See page 561.

PLATE DXVII.

INDEX.

SURINAM, one of the provinces of Dutch Guiana, which derives its name from a river of the same name in which the capital Paramaribo stands, at the distance of 18 miles from its mouth. It is bounded on the north by the Atlantic, on the east by the Marawina or Maroni, on the south by an Indian territory, and part of French Guiana, and on the west by the river Corentyn. Its extent is about 150 miles from west to east, and 60 from north to south. The chief rivers are the Surinam, the Corentyn, the Copename, the Seramica and the Marawina. These rivers are generally from two to four miles broad, and are very shallow and rocky, with numerous waterfalls. The water rises and falls about 60 miles from the mouth of the river.

The climate of Surinam is now greatly improved in consequence of the clearing of the ground and the diminution of the swamp. The thermometer ranges between 70° and 84°, and the year is divided into two dry and two wet seasons. The first wet season is from the middle of April to August, the long dry season continues from August to November. The second wet season occurs in December and January, and the second dry season in February and March. The great rains fall in the middle of June.

The banks of the creeks or rivulets, which are both large and numerous, are cultivated by Europeans, with coffee, sugar, cocoa, and indigo plantations, which present a delightful picture to those travelling by water. In the time of Capt. Stedman there were about 700 plantations producing annually more than a million sterling. He computed the number of slaves at 75,000, and the annual supply at 2500. Paramaribo, the capital, contains about 5000 souls, of whom about 1800 were whites. A full account of the Natural History of Surinam will be found in our article GUIANA, Vol. X. p. 144.

SURREY, one of the inland counties of England, is bounded on the south by Sussex, on the east by Kent, on the west by Berkshire and Hampshire, and on the north by Middlesex and part of Buckinghamshire, from which it is separated by the Thames. It is about 37 miles long from east to west, and its breadth from north to south is 25 miles. It is divided into 13 hundreds (with the boroughs of Southwark and Guildford) which contain 14 market towns and 146 parishes, in the diocese of Winchester. It contains 758 square statute miles, or about 485,120 statute acres. The annual rental is L.369,901, and the amount of tithe L.47,320. In 1806 it paid L.3,646,783 of property tax, and in 1803, L.179,005 of poors rate, at the average of 5s. 8d. in the pound. The county pays 18 parts of the land tax, and returns 14 members to Parliament, viz., 2 from Southwark, 2 from Bletchingley, 2 from Gatton, 2 from Reygate, 2 from Guildford, 2 from Haslemere, and 2 from the county. The elections are held at Guildford and the assizes once a year. The other assizes are at

Kingston and Croydon alternately. The gaol is in Southwark.

The principal river in Surrey is the Thames. The Wey is the only other navigable river, barges going above Guildford into the Basingstoke Canal, which was finished in 1796. The Mole disappears in dry weather by absorption at Boxhill, and rises again in a strong spring at the bridge of Thorncroft, where the current continues constant. Its banks are beautiful all the way to Esher. It flows into the Thames opposite to Hampton Court. The Wandle, which runs into the Thames a little below Wandsworth, though it has only a course of 10 miles, yet it turns nearly 40 mills, and employs about 40,000 people. The Medway only has its origin in Surrey. The Loddon supplies the Basingstoke Canal, and there is a nameless stream rising in the town of Ewell, which supplies several gunpowder mills at Ewell and Maldon, and a large cornmill at Kingston, where it joins the Thames. The canals are the Basingstoke, the Croydon, and the Surrey Canal, already fully described in our article NAVIGATION INLAND, Vol. XIV. p. 280.

The surface of this county is generally undulating, and presents a great diversity of scenery. The northern part of the county is most beautiful, and covered with villas. The central part is a range of chalk hills, interspersed with dry arable fields. The southern part is a flat clayey country, containing the finest oaks in Britain. The north-west district is covered with black and barren heath, and on the south-west near Farnham, we meet with the most productive land in England.

The soils of Surrey may be divided into clay, loam and chalk. The Weold of Surrey in the south, about 30 miles by 4, is a pale, cold, retentive clay. Farther north it is chiefly loam across the whole county, and near Godalming, it has great depth reposing on an iron-veined sandstone. The chalky downs now begin, and have a breadth of about seven miles. Besides the crops common to other counties, there is a great deal of clover and sainfoin cultivated on the hills, and wood is also raised in the same districts to a great extent. Plants for druggists and perfumers are extensively cultivated near London on about 350 acres, and superior hops are raised near Farnham. The waste lands occupy 73,000 acres.

The principal useful minerals are fullers' earth, which has been dug for 60 or 70 years; there are two kinds, the blue and the yellow, the last of which is the finest. Excellent freestone is extensively wrought near Godstone. When first taken from the quarry it can scarcely bear damp, but when kept for a few months under cover, it resists the heat of a common fire, and is in great demand in London and elsewhere for fire-places. Limestone is abundant, especially near Dorking, and it and chalk are made into lime on a great scale for the metropolis. The sand of Dorking and Ryegate is in great request for hour-glasses and for the manufacture of glass. Iron ore was formerly wrought at Haslemere, Dunsfold and Cranley, in the south-west of the county, and about Lingfield and Horne in the south-east; but from the high price of fuel the works have been abandoned as unprofitable.

Surrey has no particular breed of cattle. It supports about 600 cows for the supply of London with milk, which are chiefly of the short-horned or Holderness breed. Cows of the Staffordshire breed are common and highly esteemed. The cattle on the heights are poor looking, but have a fine bone. They resemble the ordinary long-horned. The horses generally employed are usually large, heavy, and black. Great numbers of sheep are bred in the central and western districts. The most common are the South Downs, Wiltshire and Dorsetshire. Great numbers of hogs are fattened at the distilleries and starch manufactories. House lamb-suckling is a great object with the farmers. In the Weold, geese are reared in great numbers on the commons. The Dorking fowls, which are large, handsome, and perfectly white, with five claws on each foot, are well known. There is a rabbit warren of about 30 acres near Banstead Downs, where 200 pair are kept. It is surrounded with a brick wall ten feet high, with openings at regular distances, within which are wire gratings or hinges. These give way to the hares when they enter, but prevent their egress. In summer they are fed on clover, rye, &c. and in winter on hay.

The manufactures of Surrey are numerous and extensive, but the most important belong to London. (See our article LONDON, Vol. XII. p. 208.) On the banks of the Wandle are large establishments for bleaching and calico printing. At Beddington there are large flour mills, skinning mills, calico-printing works and bleaching greens. At Carshalton the same business is carried on, with the addition of a large cotton factory, paper mills, and several snuff and oil mills; and Mitcham and Morton are celebrated for their extensive calico and bleaching establishments. The principal objects of manufacture are starch, tobacco, snuff, gunpowder, paper, vinegar, leather, earthenware, wax, and hats.

Among the antiquities in this county are the Ermine Street, a Roman road passing through Clapham, Epsom, Dorking, and Farnham. Stane Street Causeway, a branch of Ermine Street, begins at Dorking, and may be traced through Ockley to Sussex. Another military way has been traced through Stretham, Croydon, and Godstone, to Sussex. Vestiges of Roman camps occur at Bottlehill and Waltonhill, on the Thames. The remains of a Roman temple, surrounded with embankments, occur on Blackheath, in the parish of Oldbury. There appear to have been Roman stations at Kingston and at Woodcote, near Croydon, the last of which, Camden and Horsley consider to be the *Noviomagus* of Ptolemy.

The following was the population of the county in 1821.

Number of houses, .	64,790
Number of families, .	83,806
Number in trade,	46,811
Total population,	398,658

The population of the principal towns is as follows:

Southwark, six parishes,	85,905
Croydon town and parish,	9,254
Richmond town and parish,	5,994
Kingston town and part of parish,	4,900
Chertsey town and parish,	4,279
Godalming town and parish,	4,098
Dorking town and parish,	3,812
Guildford, borough of,	3,161
Farnham town and parish,	3,132
Ryegate borough,	1,328
Bletchingley, borough of,	1,287

See the *Beauties of England and Wales*, vol. xiv. Stevenson's *View of the Agriculture of Surrey*, Manning and Bray's *History of Surrey*, and Salmon's *Antiquities of Surrey*. See article LONDON, Vol. XII. p. 208.

SURRY, county of, Virginia, bounded E. and SE. by Isle of Wight county; by Southampton S.; Blackwater river separating it from Sussex SW.; Prince George's county W.; and James river separating it from Charles City county NW.; and James City county NE. and E. Surry county of Virginia is nearly a square of 18 miles each way, with an area of 324 square miles. Extending in lat. from 36° 50′ to 37° 11′, and in long. from 0° 19′ E. to 0° 08′ W. from the meridian of Washington City.

The height of ground between the Chowan and James river basins, passes through and divides this county into two not very unequal portions. The northern declivity falls towards and is drained into James river, whilst the southern gives source to many creeks of Blackwater branch of Nottaway river, which water is finally discharged into Chowan river.

There are no villages or towns of consequence in this county; the court-house is situated rather to the eastward of the centre; and beside one there, in 1831 post-offices existed at Bacon Castle, Baileysburg and Cabin Point.

Surry Court-house and Post-office, Surry county, Virginia, is situated by post-road 60 miles SE. by E. from Richmond, and 183 miles a very little E. of S. from Washington City. Lat. 37° 09′ N., and long. 0° 10′ E. from the meridian of Washington City.

SURRY, county of, North Carolina, bounded by the northern part of Stokes county of the same state NE.; by Yadkin river separating it from the southern part of Stokes SE.; by Rowan S.; Pedell SW.; Wilkes W.; the Blue Ridge separating it from Ashe NW., and by Grayson and Patrick counties of Virginia N. Greatest length from S. to N. 33, mean width 22, and area 726 square miles. Extending from 36° 04′ to 36° 33′ N.: and in long. from 3° 26′ to 3° 58′ W. from the meridian of Washington City. By a local curve in its general direction, the Blue Ridge forms a boundary for Surry county, North Carolina, on the northwestern and northern borders, giving source to Toms, Ararat, and Fisher's creeks, which pour their fine mountain currents southwardly into Yadkin river. The latter, a navigable stream when issuing from the valley of Wilkes into Surry, crosses the latter in a direction a little north of east, dividing the county into two not very unequal portions, and again by a rapid bend turns to a little W. of S., and forming the southeastern limit, leaves Surry, and continues its southern course between Stokes and Rowan.

From the remarkable curve of Yadkin the southern section of Surry is enclosed on two sides by that stream, and the creeks flow like radii from a common centre, though all have the Yadkin as a recipient. Taken as a whole, the general declivity of Surry is eastward.

Beside at Rock Ford, the county seat, by the post office list of 1831, there were post offices at Hamptonville, Huntsville, Jonesville, Judsville, Kincannon Ironworks, Mount Airy, Panther Creek, and Scull Camp.

Rock Ford, the seat of justice, is situated near the centre of the county, on the left bank of Yadkin river, by the post road 151 miles NW. by W. from Raleigh, and 379 W. from Washington City.

The northern and northwestern sections of Surry are mountainous, but the features soften advancing to the southeastward down the beautiful valley of Yadkin. The soil is generally productive, and comprising air, water, and variety of surface, few if any other counties of the United States exceed Surry as affording a delightful residence to human society. The population of this county was 12,320 in 1820. DARBY.

SURVEYING is the art of measuring land, or of laying down or delineating the surface of a kingdom or any portion of the globe. In our article MENSURATION, Vol. XIII. p. 57. Sect. 1, the principles of land-surveying are laid down with sufficient clearness to enable any person to apply them in practice. The more important subject of measuring a base, and of carrying on large trigonometrical surveys, and of measuring a degree of the meridian, has been treated pretty fully in our article on PHYSICAL GEOGRAPHY. Vol. XV. p. 556. Our limits will not permit us to enter more fully upon any of these subjects.

SUSA and SUSIANA. See KUSISTAN, Vol. XI. p. 637.

SUSQUEHANNA, river of New York, Pennsylvania, and Maryland, having the basin of the Delaware E.; the valley of Potomac SW.; the valley of Ohio W.; the valley of Lake Ontario NW. and N.; and that of the Mohawk branch of Hudson NE.

If the correct principles of physical geography had been pursued in the nomenclature of the rivers of the United States, the name of Susquehanna would have been continued to the Atlantic Ocean, but custom has restricted the name to that part of the river above tide water, and confirmed the name of Chesapeake Bay to the common recipient of Patapsco, Patuxant, Potomac, Rappahannoc, York, and James rivers on the west; and Pocomoke, Nantikoke, Choptank, Chester, and other smaller streams on the east.

The great physical section, however, comprised in the real valley of Susquehanna, as the name is restricted, extends in lat. from 39° 33′ to 42° 55′ N.; and in long. from 2° 25′ E. to 1° 50′ W. from W. C., and embraces an area of 28,600 square miles. A small fraction of the extreme lower part of the valley, 350 square miles, is in Maryland; above N. lat. 42° the state of New York comprises of this valley 7600 square miles, drained by the two northern branches and their numerous confluents. But the main part of the valley, 20,650 square miles, lies within, and forms the central and upwards of four-tenths of the whole state of Pennsylvania.

The Susquehanna is formed by two main branches, called with some inconsistency the northern and western branches. The northern and principal branch rises in Otsego county of New York, by two confluents, the Unadilla and Chenango. As delineated on Tanner's United States, the creek which falls into the head of Otsego Lake has its remote source within five direct miles from the Mohawk, at the Little Falls, and is the highest northern fountain of Susquehanna. Other sources pour their tribute into the Unadilla or Susquehanna from the Catsbergs. Westward from the sources of Unadilla rise those of Chenango in Madison county. Both streams assume a southwestern course, and flow nearly parallel about 50 miles, where the Unadilla, now known as the Susquehanna, sweeps an extensive curve to the southward into and again out of Schuylkill county, Pennsylvania. Returned into Broome county, New York, this already navigable river is augmented by the reception of the Chenango at Binghampton. Thence first pursuing a western course of 20 miles to Oswego, inflects to SW. separating Broome from Tioga, re-enters Pennsylvania, and at the town of Athens on Tioga Point, receives another considerable branch of the Chemung or Tioga from the NW.

Before receiving the Tioga, the eastern branch of Susquehanna has drained an elliptic valley of 110 miles in its greatest length; 65 miles where widest, but having a mean width of 45 miles, or, area 4950 square miles, embracing in New York all the counties of Otsego and Chenango, with a large part of Delaware, Broome, Tioga, Courtlandt, and Madison; and in Pennsylvania the northern part of Schuylkill, and the northeastern of Bradford counties.

The Tioga or Chemung, the northwestern confluent of the north branch of Susquehanna, is composed of three minor branches, Tioga proper, Canisteo, and Conhocton.

The Tioga rises by numerous creeks in Tioga county, Pennsylvania, draining the northeastern half of that county, and after a general course northeastward unite on the boundary between Pennsylvania and New York. Entering Steuben county New York, and flowing N. about 10 miles. The Tioga joins the Canisteo from the west.

The Canisteo has its remote sources in Alleghany, but assumes the magnitude of a river in Steuben, near the village of Canisteo. Flowing over Steuben 35 miles to the SE. and uniting with Tioga as already stated, the united water turns to a little N. of E. and receives the Conhocton at Painted Post.

The Conhocton rises in the northeastern part of Livingston county, and affords the extreme northwestern fountains of Susquehanna. Similar to most other branches of that great river, the Conhocton becomes navigable within a few miles from its source, and at Arkport in Steuben turns to SE., and continuing in that direction 35 miles unites with Tioga, and known by the latter name continues on nearly the course of Conhocton 35 miles, to its final exit into the Susquehanna at Tioga Point.

The Tioga drains a valley of about 90 miles by 30 mean width, or 2700 square miles; comprising in New York all Steuben, and a part of Alleghany, Livingston, Yates, and Tioga counties; and in Pennsylvania a part of Potter, Tioga, and Bradford counties.

Combining the two sections of this northern section of the valley of Susquehanna, we have a physical section extending from the eastern sources of Unadilla to the western of Tioga, 180 miles, with a mean width of about 48, and area 8640 square miles, of which 1040 are in Pennsylvania.

The features of this region, and its lines of connection with the adjacent vallies, present some very interesting phenomena to the geographer and statesman. On the sides towards the Schoharie and Mohawk, where the Catsbergs and other elongations of the Apalachian chains form the dividing ground between the Susquehanna and Hudson vallies, there exists no intermediate gaps except at great comparative elevation. On the contrary, between the sources of Chenango and those which flow nothwards into the Ontario basin, deep vales extend from the respective sources through the intervening ridges. It is very difficult in many places to determine the point where the waters separate. The face of the country is hilly to an extent which gives a mountainous appearance, and yet the intermediate valleys are many of them broad and marshy. Very striking examples exist in Courtlandt and Madison counties. These deep traverse vallies are not, however, peculiar to the head sources of Chenango; one of the most remarkable amongst them extends from the Tioga at Elmira, to the head of Seneca Lake.

The mean water level at Tioga Point is 723 feet above the Atlantic Ocean; and from the Point to Newtown or Elmira on Tioga river the rise is 103 feet, giving to the water level at Newtown a comparative water level of 826 feet elevation. Though the hills are very high in the vicinity of Newtown, the natural valley stretching from the Tioga river northwards to the head of Seneca Lake, has a rise of only 59 feet above the former, though the declivity on the northern side towards the Seneca has a descent of 445 feet in 10 or 11 miles. The intermediate summit level is 885 feet above the surface of the ocean, and is the lowest gap through which a canal could be formed to connect the Atlantic and interior waters of the United States, from the valley of the Mohawk to Lower Georgia. A single glance on a map of this physical region, will serve to exhibit the singular natural facilities afforded to navigation, or to the creation of artificial water channels of intercommunication, by the depression of the vallies between them, and the approximation of the St. Lawrence lakes to the northern streams of the Susquehanna.

Though so far advanced towards as to be at the extreme eastern sources within 40 miles from tide water in Hudson river, the entire northern section of the Susquehanna valley is on the interior floetz or secondary formation, and has a discharge from this formation not from but directly into the Appalachian system.

A very erroneous opinion may be here noticed and corrected. The Appalachian system of mountains is commonly regarded as a dividing barrier between river source. This is so far from being the real state of nature, that the mountain chains have in no one place in the United States distinctly influenced the general course and recipient of any river: the bends, or the inflections of the streams if viewed on a large scale, appear to be either at right angles or parallel to the chains, and give to river physiognomy a family similarity which must greatly interest the attentive observer; but the system of mountains traverses the Atlantic and Mississippi plains obliquely. It is from such a physical structure of the continent that the Susquehanna is seen pouring down from an elevation above that of the base of the mountains, against which its various branches impinge; and that these branches have in the course of time torn passages through the river rocks, and their waters gradually uniting, at length reach the level of the Atlantic tides, and gradually mingle with the waters of the Atlantic Ocean. This contest between the apparently stable mountains, and the equally apparently fleeting rivers, which began, it is most probable, with the creation, is far from being terminated. It is a feature in physical geography in a high degree, not simply favorable to their actual construction, but to excite original conceptions of canals. The rivers have, during accumulated centuries, done that which man would without their aid never dared even the conception. The rivers rising beyond have fallen with steady and irresistible weight on the mountain sides, and torn them to their bases, and given to human beings, and the fruits of their labour, a free passage:—but we must return to our subject.

Below their junction at Tioga Point, the united water of Susquehanna and Tioga, flow a little S. of E. 15 miles, to the northwestern base of the Appalachian system below Towanda, the seat of justice for Bradford county Pennsylvania. The now large stream quits the secondary and enters on the transition or inclined rocks, and to an eye above the mountains seems to sink into their recesses; but without even a cataract the volume turns to southeast, and following that general course fifty miles, breaks through several chains, and finally at the mouth of Lackawannock river, nine miles above Wilkesbarre, enters the beautiful valley of Wyoming. Inflecting at right angles it now turns to the southwest and passing the villages or towns of Pittstown, Wyoming, Wilkesbarre, Berwick, Mifflinsburg, Cattawissa, and Danville, continues the latter course by comparative distance about seventy miles down the mountain vallies to the borough of Northumberland, and to the influx of the West Branch.

The West Branch is entirely a river of Pennsylvania, having its most remote southwestern fountains, and indeed the most western fountains of the whole valley of Susquehanna proper, in Cambria and Indiana counties. These fountains rise within thirty-five miles from the Alleghany river, at Kittanning, and produce streams which unite in Clearfield, and after a comparative course of seventy-five miles to the northeastward, enter Lycoming, and receiving a large accession by the influx of the Sinnamahoning, from the northwestward, and from Clearfield, McKean, and Potter counties. Now a navigable river, the West Branch continues N. E. 20, and thence turns to S. E. 25 miles, to the influx of Bald Eagle river from the southwestward and from Centre county. Below the mouth of Bald Eagle, the course is a little north of east thirty-five miles to Pennsborough, having passed Dunnstown and Williamsport, and having received in the intermediate distance, and from the northward, Pine, Lycoming, Loyalsock and Muncy creeks. Below Pennsborough, with partial winding and an elliptic course to the westward, the general course is nearly due S. twenty-five miles to the junction of the two main branches at Northumberland, passing the villages of Watsonburg, Milton and Lewisburg.

The valley of the West Branch lies between lat. 40° 30′ and 41° 45′ N. and between longitudes 0° 33′ and 1° 50′ W. from Washington City; and if the extent is taken from the eastern source of Loyalsock, to the extreme west fountains in Indiana, the length is 140 miles. The mean width at least 50 miles, and area 7000 square miles, comprising all the counties of Lycoming, Clearfield and Centre, with very little exception on the borders of the two latter; and part of Tioga, Potter, McKean, Indiana and Cambria.

The now large and wide volume of the Susquehanna assumes a course of a little W. of S. forty miles to the great bend at the northwestern base of Kittatinny, having passed the towns of Sunbury, Selinsgrove, Georgetown, Millerstown, Halifax, and Petersburg; and received from the eastward, Shamokin, Mahanoy, Mahantango, Wicomisco, and other small rivers or creeks; and from the westward, Penn's creek, Middle creek, Shareman's creek, and the Juniata river.

Juniata, which deserves the title of the Southwest Branch of Susquehanna, rises by its most remote southwestern source on the border of Somerset, but entering and traversing Bedford county in an easterly direction, passing the borough of Bedford and the village of Bloodyrun, and rapidly augmented by numerous mountain streams, it thence abruptly bends to the northward inclining a little eastward, forty miles to the influx of Frankstown branch, a small distance below the borough of Huntingdon, in Huntingdon county. The general course of Frankstown branch is from the northwest to southeast; and below their junction the united stream follows that course fifteen miles, breaking through Jack's mountain. Again inflected to the northeast, the Juniata leaves Huntingdon and enters Mifflin county, and pursuing that direction near thirty miles, passes the borough of Lewistown, and again winding to southeast, breaks through Shade mountain into Tuscarora valley; crossing that valley in a course of ten miles reaches the northwest base of Tuscarora mountain, down which it flows northeast ten miles, where, near Millerstown, it passes the latter mountain, and once more turning to the southeast, enters on Perry county, over which it flows fifteen, to its final influx into the Susquehanna above the village of Petersburg.

In all its parts, Juniata is a real mountain stream. The current rapid, though the channels have no direct falls of any great consequence; the beds are deep, embosomed in the mountain vales, and rocky. The whole valley comprises an area of about 2750 square miles. The sources of both branches are in the slopes of the Alleghany mountain, at an elevation of upwards of two thousand feet above the ocean tides. The descent near the sources is very rapid. The general level of the farms of Bedford and Huntingdon may vary from nine to twelve hundred feet above the ocean; and that of Frankstown branch at Frankstown 910 feet. In lat. this minor valley extends from 39° 50′ to 40° 50′, and the channel of the main stream has gained great importance amongst the commercial channels of the United States, by affording a passage for the Pennsylvania canal through five considerable chains of mountains.

Augmented by the last of its large tributaries, the Susquehanna pierces Kittatinny mountain, inflects to the southeastward, and maintains that course eighty miles, receiving from the right Conedogwinet, Yellow Breeches, Conewago, Codorus, and Deer creeks; and from the left Swatara, Conestoga, Pequea, and Octoraro, with numerous smaller streams, is finally itself mingled with the water of Chesapeake bay, after falling over the lower primitive ledge of the Apalachian system; having in the latter courses passed Harrisburg, Middletown, Columbia, and Havre de Grace.

Including all its higher branches the Susquehanna is peculiar in the structure of its vallies. Wide and often highly productive bottoms of two, and sometimes three stages of relative elevation, spread along the convex side of its bends, whilst hills, or more frequently mountains, of more or less elevation, rise along both sides of these spreading vales. Exuberant fertility is, at a single step, followed by rocky and sterile steeps. The natural timber of the bottoms in most species different from that of the hills and mountains. On the former, sugar maple, black walnut, elm, beech, *leucodendron tulipifera*, white walnut, and other trees indicative of a fertile soil abound; on the slopes of the mountains pine, oak, and chesnut, and above Wyoming valley inclusive, hemlock, are the prevalent trees. As a navigable stream, or streams, if all the confluents are taken into view, independent of artificial improvement, the Susquehanna is much less interrupted by rapids, or dangerous shoals, than could be expected from the tortuous channels through an extensive mountain system. It is also perhaps peculiarly remarkable, that in the reaches where the various branches of this river traverse the respective chains, rapids but seldom, and direct falls no where exist.

Until recently the advantages of Susquehanna valley, as affording canal improvements, was theory, but the people of Pennsylvania, on their own resources, and by the authority of the legislature of the state, have commenced and considerably advanced in the execution of a system of canal, lock, and rail-road improvement. The Pennsylvania Canal has three divisions in whole or in part within the valley of Susquehanna.

Transverse division of the Pennsylvania canal has its commencement at Columbia, on the east bank of the Susquehanna and in Lancaster county. It thence ascends that great river along the east bank, intersects the Union Canal at Middletown, near the mouth of Swatara, and continuing along the same side to Duncan's Island, at the mouth of Juniata river. There crossing the Susquehanna, and following the valley of Juniata to the junction of the two main branches below the borough of Huntingdon, and thence along Frankstown branch to its termination at Frankstown.

Besides many places of lesser note, this canal passes through Middletown, Harrisburg, Lewistown, and Huntingdon.

Another section of the same system of canals is to ascend the Susquehanna, from Duncan's Island, opposite the mouth of Juniata, to the New-York line above Tioga Point; length, 204 miles; rising, 423 feet.

The West Branch section commences at the borough of Northumberland, and following the left or northern side of the West Branch river, 70 miles by a rise of 109 feet, to Dunnstown, passing by, or through Milton, Pennsborough, Williamsport and Jersey Shore.

It may be doubted whether the execution of any other line of canal of equal extent in the United States, would produce so great and permanent revolution on inland trade as would a line of navigable canals from the mineral districts on Susquehanna, into the western part of the state of New-York.

If the valley of the Susquehanna offered no other resource but the vast strata of anthracite coal in the valley of Wyoming, a line of canals in both directions would be fully sustained; but it may be questioned, whether the value of the strata of iron ore, on the waters of Juniata, do not exceed that of mineral coal, and both combined present a fund to reward enterprize, which seems to have surface without a discoverable base. In brief, whether we regard it as a physical section of the earth, or as a political and commercial link in the chain of connexion between different portions of the United States, the valley of Susquehanna deserves profound attention from the philosopher, geographer, and statesman. Darby.

SUSQUEHANNA, county of Pennsylvania, bounded on the E. by Wayne county, of the same state, S. by Luzerne, W. by Bradford, and N. by Broome county of the state of New York. Greatest length from east to west, 35, width, 26, and area, 875 square miles. This county extends in lat. from 41° 40′ to 42′ N. and in long. from 0° 50′ to 1° 32′ E. from the meridian of Washington City.

This county occupies a curious physical section. The main volume of the Unadilla, or eastern constituent of Susquehanna, curving with the Coquaso branch of Delaware, sweeps to the east of south from Broome county, of New-York, into Susquehanna county, of Pennsylvania. In the latter, the stream is turned by one of the low ridges of the Appalachian system, and bending at more than a right angle, follows northward by comparative courses about ten miles, and again enters Broome county, but gradually winding in an elliptic curve, the Susquehanna, after a comparative course of upwards of eighty miles in Broome and Otsego counties, of New York, and Bradford of Pennsylvania, approaches the SW. angle of the Schuylkill to within one mile.

It is evident from such relative position that Schuylkill county occupies a plateau, or table land. The surface is very broken by hills, and towards the eastern and southeastern sides by mountains. The central part is elevated, and the watercourses having their sources on these high vallies, flow rapidly in deep channels, and diverge like radii from a common centre.

The southeastern angle is in the valley between the Lackawannoc and Tunkhannoc mountains, and gives source to the Lackawaxen branch of Delaware, and the Lackawannoc of Luzerne county, entering the Susquehanna in the valley of Wyoming. The sources of the two latter streams are separated from those of the Tunkhannoc by Tunkhannoc mountain.

Tunkhannoc rises in Schuylkill, and within four miles from the Susquehanna at the Great Bend in the northern part of the county, but flows SW. over Schuylkill county, and entering Luzerne falls into the main volume of the Susquehanna, if the general curve is only regarded, about one hundred miles below the Great Bend. Westward again from the Tunkhannoc, rise and flow southwestwardly into Susquehanna, the Misshopper and some smaller creeks. The western part of the county is chiefly drained by the higher creeks of the Wyabyssing. The latter rises near Montrose, and near the centre of the county, and flowing to the westward enters Bradford and there bends to the south of SW. and falls into the Susquehanna nearly opposite the Wyabissing hills.

To the water courses already noticed as having their origin in Schuylkill county and flowing to the south and west, are opposed another series of creeks flowing northward also into Susquehanna, but into the eastern branch. Advancing from east to west, the latter creeks are in order, Starucoa, Conewanta, Salt Lick, Snake, Choconut, and Apollocan.

Taken as a whole this really fine county and physical section is divided by nature into two unequal declivities, the larger falling southward towards the main colume of Susquehanna, and the other in an opposite direction towards the eastern branch.

The soil of this county is generally good. Sugar maple abounds in the vallies and on the slopes of the hills. If any particular species of timber prevails in quantity, it is the hemlock, which here grows in abundance and to an enormous size. Oak, hickory, beach, ash, &c. are plentiful.

The rapid increase of population shows the value of the soil of Schuylkill county. In 1820 the inhabitants amounted to 9960, and in 1830, to 16,677, or at a rate exceeding 67 per cent increase.

By the post list of 1831, beside at Montrose, the seat of justice, there were in this county twenty-two post offices, namely at Birchardsville, Brooklyn, Choconut, Dimocksville, Dundoff, Ellerslice, Fairdale, Friendsville, Gibson, Great Bend, Harewood, Harford, Jackson, Lanesborough, Lawsville, Lawsville Centre, Lenox, New Milford, Rushville, Silver Lake, Springville and Springville Four Corners.

Montrose, the county town, is situated near the centre of the county, and on one of the higher sources of Wyabussing creek, by post road, 49 miles N. from Wilkesbarré; 163 NNE. from Harrisburg, and by the route of Wilkesbarré, 150 miles NNW. from Philadelphia. It is a very neat village, situated on an elevated and pleasant site, and, with several handsome private buildings, contains the usual edifices belonging to a county seat. DARBY.

SUSSEX, a southern and maritime county of England, bounded on the north by Kent and Surrey, on the east by Kent, on the south by the British Channel, and on the west by Hampshire. Its figure is that of an oblong, about 70 miles in length from east to west, and its utmost breadth from north to south 26 miles. It contains 1463 square miles. Its rental is L.549,950, and the amount of tithe L.100,498, the annual value of a square mile being L.445. In 1806 it paid L.1, 436,563 of property tax, and in 1803, L.206,591 poor's rates, at the average of 8s. 7½d. in the pound. It pays sixteen parts of the land-tax. It is divided into six portions or rapes, in nearly equal parts from north to south, which are subdivided into 65 hundreds, and contain 313 parishes. The county is within the diocese of Chichester, and the province of Canterbury. It is now included in the Home Circuit.

The general appearance of the country is rich and fertile. It is thickly clothed with the finest wood, which is computed to occupy an extent of not less than 170,000 acres. Formerly the whole northern part of the county was one continued forest, and it still contains some of the finest oaks in the kingdom, which are in great demand for the use of the navy. The soil in most places consists of a stiff deep clay, with the usual variations of sand, loam, gravel, and chalk; of the latter substance, there is a whole range of hills called the South Downs, which run in a direction parallel to the coast, and on which immense flocks of sheep are pastured. In the small vallies that intersect these hills, large crops of grain are raised. Near the coast there is some very fine pasture land, on which a considerable number of the valuable oxen of the county are fed, to supply the London market.

Sussex is by no means deficient in mineral productions, the principal of which is limestone, which is found in the eastern part of the district called the Weolds, in the greatest abundance and variety. It has been found to excel both that of Maidstone and Plymouth. There is also a very beautiful marble dug up in this country, called the Sussex and Petworth marble, which is capable of receiving a high polish, and is in great request for ornamental chimney-pieces. The stratum of this marble lies from ten to twenty feet beneath the surface, and is about nine or ten inches thick. The other minerals are ironstone, fuller's earth, red ochre, chalk, and marl.

The agriculture of the county, and the rotation of the crops varies with the difference of the soil. Fallowing is much resorted to in the stiff clay of the Weold, but is rarely to be met with in the district south of the Downs. The crops usually raised in Sussex, are wheat, oats, barley, clover, pease, and tares, turnips, potatoes and beans; and hops are also grown in considerable quantities. The cultivation of the hop is chiefly confined to the eastern part of the county, where it is practised on such an extensive scale as to require almost all the manure of the farm, the necessary consequence of which is, that the crops of wheat and other grain are comparatively small. In the western part of Sussex, there are some large and valuable orchards, which, when the soil is adapted to the fruit, yield a considerable produce. The best cider in the county is made near Petworth.

Sussex has been long celebrated for the excellence of its breed of cattle, which is universally acknowledged to be inferior to none in the kingdom. The distinguishing marks of a thoroughbred Sussex cow, are a deep red colour, fine hair, a small head, and clear and transparent horns, running out horizontally, and turning up at the point. However superior the quality of their flesh may be, the quantity of milk yielded by the cows, is by no means equal to that of many other breeds; in consequence of which there are few dairies to be met with, and the cattle are reared chiefly for the sake of the meat, which is of the very best quality. The oxen are much used in ploughing, in which employment they generally continue for three or four years before they are fed for the butcher. They are, however, worked very moderately, in order that their growth may not be affected, the usual number attached to a plough on ordinary soils being eight, but on a stiff soil ten and sometimes twelve. The sheep are of the well known South-Down breed, (so called from the hills of that name on which they are pastured,) which, as well as the cattle, peculiarly belongs to Sussex. They have now, however, in a greater or less degree extended themselves over most parts of the kingdom. They have black faces and legs, and no horns. Their flesh is excellent; and their wool is in every respect equal to that of Hereford. They are likewise a hardy breed, able to bear the severest storms, and requiring but a small quantity of food for their sustenance.

At present there is nothing in Sussex that deserves the name of a manufacture. There were formerly several establishments in the Weold for making iron into bars, which gave employment to a considerable number of persons. But they have been long disused, and removed to those districts where pit coal abounds, such as Scotland and Wales, where it is made at a much cheaper rate. The only other employment in which the population are engaged, besides agriculture, is that of fishing, which, in the summer season, and especially when the mackerel appear, is very productive.

The rivers of Sussex are few, and of no great importance when compared with those of most other districts in the kingdom. But their origin and courses are confined within the limits of the county. The principal are the Arun, Adur, Ouse, Lavant, and Rother, the two first of which are navigable a few miles from their mouth. The Rother forms Rye harbour, and separates the county from Kent. There is only one canal in Sussex, which joins the towns of Petworth and Midhurst with the Arun.

Sussex contains many Roman and Saxon antiquities. There are still some remains of the Stane Street road, which ran from east to west of the county, and there are several ancient camps to be seen in the vicinity of the Downs. The most remarkable of the Saxon remains are Pevensey Castle, Arundel Castle, and Battle Abbey. The others of less note are Eridge Castle, Bodeham Castle, and Bayham Abbey. In 1717 a tesselated pavement and bath were discovered near Eastbourne.

Sussex sends twenty members to parliament, two for the county, and two for each of the under-mentioned places, Chichester, Arundel, Horsham, Bramber, East Grinstead, Lewes, Shoreham, Midhurst, aud Steyning.

The following was the population of the county in 1821.

Number of Houses . .	36,283
Families	43,568
Ditto in trade	15,463
Total Population	233,019

The population of the principal towns in 1821, was as follows:

Brighton . . .	24,429
Chichester, city of . . .	7,362
Lewes, borough . . .	7,003
*Hastings, cinque port, and parishes	6,085
Horsham, borough and parish	4,575
Rye, cinque port, and parish	3,599
East Grinstead, borough and parish	3,153
Battle, town and parish	2,851
Arundel	2,511
Steyning, borough and parish	4,324
Seaford, cinque port, and parish	1,047

See the *Beauties of England and Wales*, vol. xiv. Young's *Agricultural Survey of Sussex*, and Russel's *Description of Kent and Sussex*.

* The town and port contains only 5,085 inhabitants.

SUSSEX, extreme northern county of New Jersey, bounded by Orange county of New York NE; Bergen of New Jersey E. SE. and S; Warren SW; and Delaware river separating it from Pike county, Pennsylvania, W. and NW. Length 25, mean width 18, and area, 450 square miles. Extending in lat. from 40° 54′ to 41° 22′, and in long. from 2° 3′ to 2° 40′ E. from the meridian of Washington City.

The features of Sussex county of New Jersey are in some respects not only curious, but peculiar. The county embraces a part of the valley between the Kittatinny and Blue Ridge chains, and in no part falls below an elevation of 800 feet above the surface of the Atlantic tides. On the side towards the Delaware river it is traversed by the continuation of the Kittatinny, and on the opposite side, is separated from Bergen and Morris counties by the Blue Ridge. The intermediate valley about 15 miles wide is a real table land, discharging southwestwardly towards the Delaware, Pequest and Pawlings creeks, and to the northwestward the sources of the Wallkill.

On the heads of the Wallkill, though elevated above eight hundred feet above tide water, spread marshy plains, having the aspect of the alluvial flats along the border of the Atlantic Ocean. The southeastern section on the heads of Pequest and Pawlings creeks, the country rises into hill and dale; and the transition from a comparative monotonous to a broken and diversified surface, is in no other part of the Appalachian system so rapid and striking.

The western borders between the Kittatinny and Delaware river, is a narrow slope or valley, from two to four miles wide, and extending the entire length of the county. Along this confined declivity flows the Flatkill, 17 or 18 miles between the mountains on the SE. and Delaware river NW. and seldom two miles from either.

The Morris canal touches, but only merely touches, the southeastern angle of Sussex. The summit level of this canal is at the place where it passes the Blue Ridge, 915 feet above the surface of the Atlantic Ocean.

The author of this article traversed Sussex in the latter part of September, and proceeded from Newburg on Hudson river, by Goshen, Newton, and by Somerville to the Delaware at New Hope, and had a fair opportunity of seeing the difference in the advance of the season at the different points. In Sussex early frost had destroyed tender vegetables on the high plains and vallies of Sussex, whilst no similar effect was perceptible on the Hudson, nor had frost yet occurred on the Delaware.

By the Post-Office list of 1831, there were post-offices in Sussex, at Andover, Augusta, Benville, Bevins, Branchville, Coursenville, Deckertown, Flat Brookville, Fredon, Gratitude, Greenville, Hamburgh, Lafayette, Lockwood, Monroe, Montague, *Newton*, Sandyston, Sparta, Stanhope, Stillwater, Vernon, Walpack, and Wartage.

Newton, the seat of justice, is situated on an elevated site and on the waters of Pawlings Kill or creek, 40 miles NE. from Easton, 60 miles NW. by W. from the city of New York, about a similar distance SW. from Newburg, and by post road, 70 miles very nearly due N. from Trenton, and 228 miles NE. from W. C. N. lat. 41° 3′, long. 2° 9′ E. from the meridian of Washington City.

The village is small, with the ordinary buildings for public use at a county seat. The adjacent country is diversified and pleasant to the eye.

When the census of 1820 was taken, Sussex county embraced the area now included in Warren, and of course, the aggregate population 32,752, was that of the superficies now constituting both counties. DARBY.

SUSSEX, the most southern county of the state of Delaware, in the United States, bounded on the N. by Kent county, Delaware; NE. by Delaware Bay; E. by the Atlantic Ocean; S. by Worcester county, Maryland; SW. by Somerset county, Maryland; W. by Dorchester county, Maryland, and NW. by Carolina county, Maryland. Greatest length from the Maryland line to the northern bend of Mispillion creek, 36 miles. The utmost breadth from west to east very nearly equals the length, but the area being about 910 square miles, the mean breadth will be 26 miles. This county lies between lat. 38° 27′, and 38° 58′ N.; and between long. 1° 14′ and 1° 58′ E. from W.C.

Though the surface of this county is level, and in part marshy, it is nevertheless a table land, from which flow southwardly the extreme sources of Pocomoke river; southwestwardly, those of Nantikoke river; eastwardly, Indian river, and other confluents of Rehoboth bay; and Broad Hill, Cedar, Mispillion, and some other creeks flowing northeastwardly into Delaware bay.

The surface being so nearly a plain admits of little variety. The soil, if taken generally, is of middling quality. Population in 1820, 24,057.

By the post office list of 1831, beside Georgetown, the county seat, there were post offices at Bridgeville, Cannon's Ferry, Concord, Dagsborough, Laurel, Lewis, Millsborough, Milton, and Seaford.

Georgetown, the seat of justice, is situated near the centre of the county, 40 miles a little E. of S. from Dover, the seat of government of the state of Delaware, and by post road, 122 miles a little S. of E. from Washington City. N. lat. 38° 40′, long. E. from W. C. 1° 39′.

Dagsborough is on Pepper Creek branch of Rehoboth bay, 14 miles SE. from Georgetown. Bridgetown is situated on a small branch of Nantikoke river, and in the northwestern part of the county.

Lewistown, or Lewis, is situated on the extreme southern arch of Delaware bay, W. from Cape Henlopen. The Delaware break-water has given additional importance to Sussex county as a part of the maritime coast of the United States.

SUSSEX, county of Virginia, bounded by Southampton, SE.; Greensville, SW.; Dinwiddie, W.; Prince George, NW.; Black Water river separating it from a part of Surry, N.; and by the southernmost angle of Surry, NE. The greatest length is a diagonal extending from west to east 37 miles;

mean breadth 16, and area 592 square miles. Lying between lat. 36° 42′, and 37° 7′ N., and in long. from 0° 2′ E. to 0° 46′ W. from the meridian of W. C.

This county has a southeastern declivity, down or rather over which the Nottaway river winds by a wide sweeping curve, first east, thence northeast, east, and finally southeast, into Southampton county. The eastern part is drained by Black Water river, but here again the descent of the plain is to the southeastward. Sussex is an undulating surface, within the climate in the United States where cotton can be cultivated as a staple commodity.

Besides at Hunting Quarter or Sussex Court House, there are by the post list of 1831, post-offices at Conan's Well, Littleton, Parham's Store, and Rowanty.

Hunting Quarter, the seat of justice, is situated near the centre of the county, and though not actually on the Nottaway river, that stream semicircles it by a bend from the west, thence round by north to southeastward, as noticed in the description of the county. This place by post road is 172 miles a little west of south from Washington City, and 50 miles SSE. from Richmond. N. lat. 36° 50′, long. 0° 22′ W. from the meridian of Washington City.

Sussex county of Virginia contained, in 1820, a population of 11,884.

Darby.

SUTHERLAND, one of the most northerly counties of Scotland, extending across the island from the Atlantic to the German Ocean. It is bounded on all sides by the sea, except on the north-east by Caithness, and on the south by Ross-shire. The length, from east to west, varies between 45 and 50 miles, and its breadth, from north to south, between 35 and 50. It contains 1865 square miles of land, and 38 square miles of salt water lakes, or 1,193,940 English acres* of land, and 24,230 of lakes. It is divided into 13 parishes, which belong to the synod of Sutherland and Caithness.

The western coast of Sutherland is a succession of inlets of the sea, variegated with bold promontoties, and numerous rocks and islets. The interior, which is almost universally wild, rocky and mountainous, may be divided into three districts. The eastern is a level piece of land on the east coast, about a quarter of a mile broad, and is sheltered from the north by a ridge of mountains, from 300 to 800 feet high. The middle district is occupied by the four straths of the rivers of Helmsdale, Brora, Fleet, and Oickel. Black cattle and sheep form here the wealth of the farmer. The western district, which borders on the Atlantic, is wild and mountainous. The mountains of Ben-mor, Assyant, Glass-bhein, Ben-canap, Benchoinag, or the sugar loaf mountains, Ben-evie, Craig-rou, Benmore, and Stackben are of great altitudes, and though entirely barren, yet at their base they display many extensive and well managed farms.

There is little more than one acre in a hundred cultivated in this county; the whole extent of cultivated land, grass pastures, and woods not exceeding 60,000 acres. Wheat grows well in the eastern district, and sometimes ripens as early as in England. Since 1818, extensive fields of wheat, drilled on the Norfolk system, have been sown; several hundred acres of turnip have been sown upon the ridge, and excellent crops of barley and clover have been raised. Oats, bear, and potatoes are raised by the small tenants in the inland straths. The number of sheep is calculated at about 140,000, yielding about 18,000 stone of wool, 24 lbs. per stone. The small tenants, on the south-east coast, pay a rent according to the quantity of grain that may be sown, which is from 15s. to 20s. per boll, which is paid partly in money and partly in oatmeal and bear. In other parts the tenants pay in proportion to the number of black cattle they can support.

The county of Sutherland has derived immense advantages from the admirable establishments of the Marquis of Stafford. Formerly the only manufacture was that of kelp, to the extent of 250 tons annually. Very important fisheries are carried on in the west, north and east coasts. At Helmsdale, on the east coast, the Marquis of Stafford has expended large sums in erecting buildings necessary for this purpose, and the tenants who had been removed from their farms have embarked with much success in this new profession. A considerable number of boats are occupied in the cod, ling, haddock, and herring fisheries, on the north and west coasts, where lobsters and mussels are also obtained in abundance. In 1814, there were caught at the village of Helmsdale 2400 barrels of herrings. This quantity increased annually, and in 1827 it amounted to 20,600 barrels. In 1814 not a single boat entered this creek, whereas in 1819 no less than 5246 ton of shipping entered there. A regular trade has been established with Leith, and other branches of industry have begun to flourish.

In this county both coal and limestone have been recently discovered. The coal is now wrought to a considerable extent on the little rivulet of Brora, and it is conveyed by a railway to the harbour at its mouth. The small coal is consumed at the salt-works there. It is employed also in burning lime and making bricks; it is not so good for domestic purposes. A general account of this coal field is given in our Article Scotland, Vol. XVI. p. 694. and in Mine, Vol. XIII. p. 340. The west coast is in a great measure formed of this mineral; but as it is in many cases combined with magnesia, its utility as a manure is diminished. It is also found in some parts of the interior. The marble quarries of Lechmore and Leadbeg, yielding a pure white marble, like alabastar, were for some years wrought by Mr. Jopling from Newcastle, but we understand they were abandoned on account of the magnesia. A fine black marble, streaked with yellow veins, is found at Edderachillis. Near the coast the limestone is sometimes found in the state of marble. Traces of ancient iron mines are said

* Some other statements make it 1,840,000, deducting 32,000 of salt water lakes.

to have been found on the west coast. Gold is found near Helmsdale, garnets on the coast, in the parish of Tongue, and it is said that lead ore rich in silver, and a vein of black manganese, have been found near the Dornoch Frith. Purple fluor spar is found in the gneiss and granite. White actynolite, approaching to tremolite, is found near Standa, and schistose actynolite is also found in the county.

In the limestone rock, on the north coast, there are some remarkable caves, one of these at Smoro, to the east of Balnaheel and Durness, is 96 feet wide and 60 feet high; another at Fraisgill is 50 feet high and twenty feet wide at its mouth, gradually contracting till it terminates at the end of half a mile.

The principal streams are the Oickel or Firth of Dornoch, Fleet or Strathfleet, Broro, and Helmsdale. The Oickel is navigable for 12 miles for ships of 50 tons, and about eight miles farther for boats. These streams rising in the interior fall into the Dornoch Firth; but others, such as the Strathy, the Naver, and the Dinart, the Hallidale, the Kenloch, the Hope, and the Eribol, flow towards the northern and western shores.

The principal lake in this county is Loch Shin, extending 20 miles from NW. to SE. and about a mile broad. It abounds with salmon and trout. Loch Assynt is six miles long and one and a half broad. The others are Loch Naver, Loch Hope, Loch Lyal, Loch More, Loch Brora, and Baden Loch, all abounding with trout.

The valued rental of the county is L.26,193 9s. 7d. which is divided among seventeen proprietors, the Marquis of Stafford having L.16,951, Lord Reay L.3720, Skibo L.1975, Bighouse L.900, and the rest between L.200 and L.500. The real rent has been estimated at L.40,000 sterling. A superiority of L.200 Scots gives a vote for the member of Parliament, when L.400 is necessary in the other Scotch counties. The number of freeholders was 22 in 1828. Dornoch, the country town, is a royal burgh, which, along with Dingwall, Tain, Wick, and Kirkwall, sends a member to Parliament. The town is small. A part of the old cathedral, said to have been built in the 11th century, is kept in repair as the parish church. The ruins of the bishop's castle, which seems to have been a stately building, still remains. Dornoch contains only 132 houses, 140 families, 58 of whom are in trade, and 9630 inhabitants.

Among the antiquities of Sutherlandshire are two circular buildings, Dun-Dornadil and Castle Coll. Dun-Dornadil, in the parish of Durness, is in a ruinous state. Only a portion of the wall is standing, which does not exceed 18 feet in height. The area seems to have been enclosed by two concentric walls, and a large triangular stone serves as a lintel to the doorway. Castle Coll, on the east side of the county, has a circuit of 162 feet, with walls 13½ feet thick at the base, inclining inwards nine inches for every three feet of altitude. On each side of the doorway are two small apartments. Both of these buildings consist of large stone nicely joined together without cement. Cairns and tumuli are very numerous. In the isle of Oldney is a considerable cairn with a hollowed stone, having a cover likewise of stone. The first of these stones is said to have contained a rounded one of various colours. On the east coast is a rocky precipice called Craigbar, fortified with a ditch of circumvallation.

The population of Sutherland in 1821, was as follows:—

Parishes.	Inhabited Houses.	Families.	Population.
Assynt, . .	547	547	2803
Clyne, . .	399	432	1874
Creech, . .	389	389	2364
Dornoch, . .	651	660	3100

Tongue, . .	318	350	1736
Total	4654	4822	23,840

See Forsyth's *Beauties of Scotland.* Henderson's *General View of the County of Sutherland*, and *An Account of the Improvements of the Marquis of Stafford in Sunderland*, by James Loch, Esq. M.P. See also our Article Scotland, *passim.*

SUTTON, Coldfield, a market town of England, in Warwickshire, which is on the high road from Birmingham to Litchfield. It is a small town, consisting of a spacious street, with several smaller ones. The church is a large handsome structure, with a new channel and two side aisles. There is a grammar school founded by Bishop Vesey. A few manufactures connected with Birmingham have been advantageously introduced. The bleak district called the *Coldfield*, to the west of the town, contains 13,000 acres. To the north-west of the town is Sutton Park, containing 300 acres, belonging to the poor of the town. They receive from it peat, and obtain pasturage for their cows. The Roman street of Icknield passes through it.

Population of the parish in 1821. Number of houses 677, families 706, ditto in trade, 227. Total population, 3466. See *Beauties of England*, vol. xv. p. 295.

SUWAROF, Rymnikski Alexander Count, a celebrated Russian general, descended of a Swedish family, was born in 1730, and died on the 18th May 1800, at the age of 70. An account of his military career will be found in our articles Britain, Franoe and Russia.

SWABIA, one of the ten circles into which Germany was divided by Maximilian I. It now forms part of Baden, Bavaria, and Wirtemberg, and is consequently described under these articles. See our article Germany, Vol. IX. p. 704—709.

SWAFFHAM, a market town of England, in the county of Norfolk. It is situated on high ground, and consists of a principal street, on the high road from Lynn Regis to Norwich, with several smaller ones branching off to the north and south. Most of the houses, particularly those in the market place, are handsome. In the centre is a large open area, with a pool of water. The principal public building is the church, which is a handsome edifice with a nave, two aisles, two transepts, and a well proportioned and lofty tower, surmounted with enriched embrasures and purfled pinnacles. The nave is lofty, and has twenty-six cleristory windows, with a highly ornamental inner roof. The other public edifices are a Quakers' meeting house, and a new assembly room on the west side of the market house. Races are held annually about the end of September, on an extensive heath near the town. A great cattle market is held here. Population in 1821:—The town and parish contained 553 houses, 587 families, 263 families in trade, and 2836 inhabitants. See the *Beauties of England*, vol. xi. p. 272.

SWANSEA, a town of South Wales, in the county of Glamorgan, "which, from its population and commercial importance, is entitled to be ranked as the metropolis of the county, if not of the principality of Wales." It is situated on the west bank of the Taw, on a point of land near the junction of that river with the sea. It is nearly two miles long, including the suburb of Greenhill, and half a mile broad. There are many streets, with a great proportion of well built houses. The church is a handsome building, with a suitable aisle, two side aisles and a large quadrangular tower at one end. It is 72 feet long, and 54 wide. The town hall, erected on a part of the castle inclosure, in the middle of the town, is a spacious and elegant modern building. A commodious theatre, and some public rooms have been lately erected. The latter form a mis-shapen pile of buildings. The castle is situated on an elevated spot in the middle of the town, and would have a grand appearance, were it not buried among houses. A lofty circular tower is the principal portion that remains. On the eastern side of the tower a large part of the original building is standing, surmounted by an elegant parapet with arched openings. The habitable apartments form a poors' house and a debtors' goal.

Swansea is the resort of numerous bathers, and warm and cold salt water baths have been made in the burrows, and near the pottery by the river side. Handsome lodging houses, the chief of which are at Mount Pleasant, and the Burrows, have been erected for the same purpose. There are at Swansea, places of worship for various dissenters, and the Presbyterian meeting house is one of the oldest in South Wales. There is here a public library, a free school, and several Lancasterian and other schools for the poor. A weekly newspaper has been long established here.

There are in Swansea various important manufactures, arising from the abundance of coal and iron in the neighbourhood. There are two pottery establishments, on a large scale, furnishing almost every article of the Staffordshire ware, of the first quality. There are also two large copper houses, to which ships of 200 tons can sail, an iron foundry, two roperies, several tan yards, a soap manufactory, an extensive brewery, and a dry dock. Swansea carries on an extensive commerce, which is greatly aided by the Swansea canal, and the Oystermouth railway, both of which we have already described in our article NAVIGATION, *Inland*.

The number of vessels which cleared out in the following years, are as below:—

	Vessels.	Tons.
1788	694	30,631
1790	1697	74,926
1800	2590	154,264
1810	2717	171,672

Swansea is a corporate town, and shares the privileges of Cardiff as a contributory burgh, in returning the member for that place. It is governed by a portrieve, twelve aldermen, two common attornies, a town-clerk, and two sergeants at mace. The population, in 1821, of the town and franchise, with the hamlet of St. Thomas, which has only 248 inhabitants, was as follows:—

No. of Houses,	2,049
Families,	2,124
Families in Trade,	739
Total population,	10,355

The increase of population since 1811, in the town and franchise of Swansea, which is 2082, is attributed to the improved state of trade and commerce in that town and port, and to the public spirit of the inhabitants of its vicinity. See the *Beauties of England and Wales*, vol. xviii. p. 720; NAVIGATION, *Inland*, Vol. XIV. p. 285; and GLAMORGANSHIRE, Vol. IX. p. 741.

SWARTZ OLOF, See BOTANY, Vol. IV. p. 26.

SWATARA, river of Pennsylvania, rises by numerous branches in the deep mountain vallies in the southern part of Schuylkill county. It thence flows in a south-western direction over the western part of Lebanon and the southern part of Dauphin county, falling into Susquehanna river immediately below Middletown, after a comparative course of 40 miles.

The valley of this fine small river, for nearly one half of its course, is now made a navigable route by means of the Union Canal. By its numerous branches, it drains a section of Schuylkill county, the extreme western angle of Berks, all Lebanon, except a very confined angle in the extreme south. and the southern and finest part of Dauphin county. The valley of Swatara is about 40 miles long, with a mean width of 15, and embraces an area of about 600 square miles.

The western side of this valley is mountainous and all parts are hilly. With the exception of the higher north western sources, the Swatara valley is in the mountain valley between the Blue Ridge and Kittatinny mountains. Along the former ridge and spreading from 5 to 8 miles wide, extends a zone of limestone, on which the soil is in a high degree productive. The limestone tract is followed by slate land towards the Kittatinny range. On the latter zone the surface becomes more broken and soil less fertile; but even in the mountain vales above the Kittatinny, some belts of fine meadow and arable lands skirt the streams. DARBY.

SWEDEN.

SWEDEN. Respecting the origin of this word, there have been several conjectures. The inhabitants of the country which it denotes are supposed to have been the *Sitones* mentioned by Tacitus, an appellation probably derived from the chief town *Sietuna*. (*De Mor. German.* cap. 44-5.) This hypothesis is not fanciful; but the more probable opinion is, that the term in question is derived from Suitheod or Sweireke according to the more modern orthography, a Scandinavian word signifying a country whose woods have been burned or destroyed. From this term, softened by its conversion into the Latin speech, the *Sitones* of Tacitus may without any impropriety be supposed to have been derived.

The country of Sweden has at various times been of very different extent. And even within the present century, it has undergone great changes in this respect. In 1809, it lost Finland, a province which has since belonged to Russia, and which in superficial extent is equal to England, and contains a population of upwards of a million; and in 1814 it added Norway to its territories in return for ceding to Prussia the island of Rugen, and the province of Swedish Pomerania. This exchange, so favourable to the country under review, was guaranteed and confirmed by the Congress of Vienna in 1815. Sweden, exclusive of Norway and Finland, but including Swedish Lapland, extends from south to north 1150 miles, namely, from 55° 20′ to 71° 10′ north latitude; and from east to west, it averages nearly 300 miles. From its sloping situation, its breadth cannot be known from the degrees of longitude within which it lies; at its extreme diagonal points it measures from 11° 10′ to 23° 30′ east longitude. The area which it embraces has been calculated at 168,802 square miles. It is bounded on the east by the Baltic, gulf of Finland, and Russia; on the north by Norwegian Lapland; west by Norway; south by the Sound and the Baltic.

This country has been divided into three provinces, namely, Gothland on the south, Sweden Proper in the middle, and on the north Norrland, including Swedish Lapland.* These provinces have been recently subdivided into districts called *Laens* or Stadholderships, of which the following is a list, together with the ancient division:—

Gothland.

Divisions, called Laens *or Stadholderships.*

New Division.	Old Division.	Sq. miles.	Capitals.
Gottenburg.	West Gothland.	1835	Gottenburg.
Halmstadt.	Halland.	1963	Halmstadt.
Christianstadt, and	Schonen, or Scania.	2174	Christianstadt.
Malmoe.	———	1750	Malmoe.
Carlskrona.	Blekingon.	1088	Carlskrona.
Calmar.	Smaland, and Island of Oeland.	4181	Calmar.
Kronsberg, or Wexio.	Smaland	3495	Merioe.
Jonkoping.	Smaland.	4267	Jonkoping.
Linkoping.	East Gothland.	4305	Linkoping.
Skaraburg.	West Gothland.	3207	Mariestadt.
Elfsburg.	West Gothland, and Dallen.	3008	Wenersburg.
Wiseby.	Island of Gothland.	1045	Wiseby.
Sweden Proper.			
City and district of Stockholm, Drottingsholm.	City of Stockholm Upland, and Sudermanland.	2624	Stockholm.
Upsal.	Upsal.	2261	Upsal.
Westeras.	Westmanland.	2793	Westeras.
Nykoping.	Sudermanland.	2880	Nykoping.
Orebro.	Westmanland, & Nericke,	3670	Orebro.
Carlstadt.	Wermeland.	6550	Carlstadt.
Norrland, including Swedish Lapland.			
Falun, or Storakopperberg.	Dalecarlia.	12,587	Falun.
Geffeberg.	Herjedalen, Helsingland and Gertricia.	7765	Gefleberg.
Hernosand.	Medelpad, Jamtland, and Angermandland	18,261	Hernosand, and Oestersund.
Umea.	West Bothnia, & Swedish Lapland	75,093	Umea.
		Total square miles, 168,802.	

The climate of this extensive country varies much in different places. The southern provinces may be compared to Scotland, which lies under the same parallel. In the middle and northern districts it becomes proportionally rigid and severe; so that in Swedish Lapland, which extends beyond the 71° of latitude, the cold is as intense as in the northern parts of Russia. The Gulf of Bothnia is frozen during several months in winter, and affords a communication by ice between the people on the opposite shores. In the southern latitudes, flowers and fruits are produced in great variety and abundance; but these productions become extremely rare beyond Gefle, a town a hundred miles beyond Stockholm. Oats are not to be found beyond that town; but forests of pine and fir extend to the 66th degree. In more distant latitudes the beech disappears: in Swedish Lapland, the oak draws out a dwarfish and sickly existence, and is at length succeeded by the birch; a tree which seems the most capable of enduring cold, and which, even under the Polar circle, is known to grow at an elevation of 1483 feet. Barley and oats are cultivated in Sweden at the 70th degree, while in North America they are not yet known beyond the 52d. Some plants, indeed, the lichen for example, though not unknown in central Europe, are regarded as indigenous in Lapland. Other particulars connected

* In this sketch we shall confine ourselves solely to Sweden, as it now stands, referring our readers to NORWAY for an account of that country; to RUSSIA, for an account of Finland; to PRUSSIA, for a description of Pomerania.

with the climate of this country, cannot be better given than in the words of Voltaire. "Winter reigns here nine months in the year. There is neither spring nor autumn: the heats of summer succeed all at once to an excessive cold; and it freezes from the month of October, without any of those insensible gradations which elsewhere bring on the seasons, and which render the change more agreeable. Nature, in recompence, has given to this rude climate a serene sky, and a pure air. A very short interval elapses between the disappearance of the snow and frost of winter, and the rich verdure and luxuriant vegetation of summer: a circumstance owing to the rapidly increasing length of the day, and the strength of the heat of summer. In the extreme north, indeed, the sun is visible for several weeks in succession. The long nights of winter, in like manner, are rendered comparatively mild, by the *aurora borealis*, by the extreme length of twilight, and by the light of the moon, which is there obscured by no cloud, augmented still by the reflection of the snow which covers the earth; insomuch that travelling in winter takes place in Sweden by night as well as by day. (*Histoire de Charles XII. liv. I.*)

Of this great extent of country the population is not great. The number of inhabitants, in November 1828, was ascertained to be 2,860,000, or so small as only to average about 17 to a square mile. There is, as may be conjectured, great difference in this respect, in different provinces. Gothland contains about 42 to a square mile; Sweden Proper about 24; while Norrland, including Swedish Lapland, not much above 2. The relative density, when compared to other countries, may be understood, when it is mentioned, that the average population of the Netherlands is 212 to a square mile; of England and Wales 207; of the Lowlands of Scotland 127. But the population of Sweden is advancing at a considerably rapid ratio; the best mark of the prosperity and increase of the capital of the country. Between the year 1820 and 1825, it advanced at the rate of $7\frac{3}{10}$ per cent.; an increase greater than at any former period; though it must, at the same time, be confessed, that between 1825 and 1828, the progress has been comparatively small, being only 37,000 per annum, or about 4 per cent.* Longevity, however, is extending: a fact that is found always to result from the improved condition of the people with regard to food, clothing, and cleanliness. During the five years previously to 1821, the annual average of mortality was 62,329; while, during the succeeding five years, it was only 58,919, making an annual reduction of 3410. Previous to the age of ten, the mortality of boys was ascertained to be greater than that of girls; between that age and that of twenty, it was nearly equal between the sexes; from that till sixty, it was greater among the males; beyond sixty, it became more prevalent among the females: and with regard to both sexes, it was found to be greatest between the ages of sixty and seventy-five. During the five years last specified, 26 individuals, namely, nine males, and fifteen females, exceeded a hundred years of age: of whom six men and eleven women reached 101; two men 102 years; two women 103; one woman 104; one man and two women 105; while one woman attained the age of nearly 107; a proof that the female life, in this instance, considerably exceeds that of the opposite sex. During the same *lustrum*, the annual number of marriages was 23,772,—of which, 18,764 were of persons before in a state of celibacy; 2,628 were of widowers who united themselves to maiden females; 1611 of widows who married bachelors; while 768 widowers married widows. In the same five years, there were 101,941 marriages for the first time; 16,092 for the second; 774 for the third; 48 for the fourth; 5 for the fifth; and only a single instance of one that married for the sixth time. During the same time also, there were 7148 instances of twins: 100 instances of three at a birth; 3 instances of four. The average number of births was 95,706, while that of deaths, as before stated, was 58,919. The greatest number of births was found to be in the month of September; the smallest in that of June. The proportion of illegitimate children was as 1 to $13\frac{3}{10}$.†

The condition of the people may be thus classified. The number of the clergymen is 3476; that of public teachers, paid by government, is 968. The army extends to 31,000, exclusive of the national militia; marines, of every kind, amount to 10,000. Manufacturers and miners exceed 28,000. None of these calculations include children or servants. The number of poor, including mendicants, is 21,216; that of prisoners, 1833. The peasantry, including their children, amount to no fewer than 1,594,703, more than the half of the whole population.

As the population and the climate of Sweden are so various, its physical appearance must evidently partake of a similar character. Rivers, lakes, mountains, forests, vales, so abound and so succeed each other, as to impart a character equally picturesque, magnificent, and interesting to this northern region. Rich pastures, or cultivated fields, barren rocks, rugged mountains, or foaming cataracts, and scenery of the most opposite description, are so peculiarly blended, that there is, probably, no country in Europe where such contrasts, and such a variety of surface may be seen. Sweden has, of late years, been much denuded of its forests, though these still extend over immense tracts, being calculated to cover about a third of the whole country. Towards the north and west, it exhibits chains of lofty and almost inaccessible mountains, an account of which may be found under the article NORWAY. Sweden, however, is not remarkable for any thing so much as for the number and extent of its lakes and rivers. The former have been computed to

* Conjectures to account for this decrease may be found under the head *Commerce*.

† The government of Sweden, so far back as 1749, appointed a commission, to give quintennial reports on the population of the kingdom: a measure which did great honour to that government, and which has not even yet been adequately imitated in other countries. This commission has been ever since kept up: and to the returns made by it, we are indebted for the above important and curious abstract, which, had our limits admitted, we would have gladly extended. (*Revue Encyclopedique*, for February 1829, Coxe's *Travels*, iv. 134.)

occupy 9200 square miles, or about an eighteenth part of the whole surface; while the number of the latter, none of which are very large, though many of them are navigable, is greater than that of any other country in Europe.

No country in the old world can rival Sweden in the extent and number of its lakes. Wener, lying between Skaraberg and Carlstadt, is the largest, being about 100 British miles in length, and 60 in breadth. It is remarkable, however, for little except its great extent. "Its shores," says Mr. Coxe, "are low and level, so that the view over the surface of the water appears boundless like a sea." "The shores of the lakes," says Mr. Derwent Conway, "are not particularly interesting; nor was there any thing to see but a vast expanse of water, enlivened by so few sails, that a feeling of sadness, rather than any other emotion, was produced in viewing so vast an arena of water contributing so little to the utility of life." (*Personal Narrative of a Journey through Norway, Part of Sweden, &c.* Part III. Chap. I. Coxe's *Travels through Sweden, &c.* vol. i. p. 302). Wener receives the water of 24 rivers, while it is connected with the Cattegat by one only, the Gotha. It is studded with many romantic islands. The Weter is next in importance after the one now described, and lies about 40 miles to the south-east of it. It is of equal length, namely 100 miles, but its breadth, which is irregular, no where exceeds 20. It is of a different character from the Wener, being surrounded by mountains, so that it is peculiarly liable to storms and hurricanes. Its surface is also variegated by numerous islands: and though its communication with the Cattegat is by a single river, the Motala, it forms the reservoir of no fewer than 40 streams. The Maeler, the only other lake that requires to be minutely described, is like Weter, of irregular form, its greatest length being about 80 miles, its mean breadth about 18. Its islands are numerous and picturesque; on seven of which, on its east coast, is situated Stockholm, the capital of the kingdom. The waters of the Maeler discharge themselves at this place into an inlet of the Baltic. The only other lake in Gothland or Sweden Proper, is Hiemar, south-west from that of Maeler, a sheet of water chiefly remarkable for its utility in the line of canals which connects the Cattegat with the capital. Many other lakes in the northern portion of the kingdom, some of them of considerable extent, might be mentioned; but as none of them is very large, or of much practical use, such an enumeration is unnecessary. The largest is Enara in Swedish Lapland, 70 British miles in length, and 30 in breadth. All the lakes which we have described, or to which we have referred, abound with fish of almost every variety; and their banks are skirted with woods or forests, even to the margin of the water.

Sweden is as remarkable for the number of its rivers as of its lakes; though of the former, none deserve notice on account of its size or extent of course. They are indeed in this respect comparatively uninteresting. Not a few of them exhibit the form of creeks, or, like the Motala already mentioned, form outlets to the lakes. The most important is the Gotha, which, as already stated, serves as the outlet of Lake Wener, and which falls into the Cattegat by two branches, the one passing through the town of Gottenburg, the other a few miles north. This river, soon after leaving its parent lake, being impeded by rocks, forms at Trolhetta one of the finest cataracts in Europe. The width of the river between the falls and the lake varies between 300 yards and a mile; but at Trolhetta, two opposite ridges of mountains approach its banks so closely that the stream is confined within a channel of 400 feet. There are four successive falls, the perpendicular height of the whole, considered as one, is about 100 feet. The falls are separated by whirlpools and eddies, "forming," as Coxe remarks, "during the whole way, the most awful scenery, ever varying, and too sublime to be accurately described." "The roar of waters," says Mr. Conway, "was greater than that of any fall I had ever before visited; and now that several years have elapsed during which I have travelled in other countries, I may say greater than that of any water-fall I have ever since seen." The river Dahl, next in importance to the Gotha, is also celebrated for a cataract, described as scarcely inferior to that of the Rhine at Schaffhausen. This river, which rises in the Norwegian alps, and which, after a course of 260 British miles, falls into the Gulf of Bothnia, presents the cataract in question, not far from its mouth. The breadth of the stream is about 400 feet, and the perpendicular height of the fall is between 30 and 40. A ridge of rocks and a high islet about a quarter of a mile in circumference, divides the stream into three parts, making as many falls. The basin below is scarcely 100 feet wide, so that the white spray rising in dense clouds, and the struggling of the waters for vent, constitute one of the most striking features of the scene. (*Wraxall's Northern Tour*, p. 158). The Tornea forms the boundary between Sweden and Russia on the north, and after flowing about 300 miles, enters the northern extremity of the Gulf of Bothnia. In addition to the rivers previously given, we may mention the Angermann, the Umea, the Skelleftea, the Pitea, the Lulea, the Calix, all flowing into the Gulf of Bothnia. Their course varies respectively from 200 to 300 miles; and though in winter their channels are comparatively empty, owing to the frost-bound mountains from which they flow, in summer, when the snow melts, they not unfrequently overflow their banks, and inundate large tracts of the adjacent districts.

As connected with the rivers and lakes of Sweden, reflections on its internal communication immediately obtrude themselves on our attention. There is no country either in the old or new world on the same parallel of latitude, in which such communication is under more favourable circumstances. Where the river Gotha is rendered innavigable by the intervention of the cataracts of Trolhetta, a canal has been cut through a solid rock of granite of two miles in length, and 150 feet in height. This stupendous work had been long contemplated; and during the last century many plans were successively adopted, all of which proved abortive; and it was not till the year 1800 that it was completed. The execution of it was reserved for a private company; and it gives us pleasure to state that during the year after it was opened, there passed through it no fewer than 1380 ships of various sizes, laden with iron, steel, timber, herrings, grain, and flour; and that it pays 12 per cent. on the capital invested on it. A canal uniting the lakes in the province of Darlecarlia with the Maeler has been completed. Other similar works are contemplated, or have been begun, or are finished. The canal of Gothland, extending from Gottenberg to Norkioping on the Baltic, thus connecting the two opposite seas, is either finished or nearly so. It passes through the most fertile portion of Sweden, and promises to be of incalculable advantage. Its length is 240 miles, including the lakes through which it flows. Lake Hielmar communicates with the capital by means of a canal; and two others of smaller extent are forming. The government is very liberal in spending money on such works; indeed, considering the scanty means of the nation, the present sovereign is entitled to the greatest praise for what in this department he has achieved. Several of the largest of the rivers are navigable, as well as many estuaries and inlets of the sea.*

Sweden is not more celebrated for any thing than for the state of its roads. "The high roads," says Mr. Coxe, (*Travels*, vol. iv. p. 35), "wind agreeably through the country, are made with stone or gravel, and are as good as our turnpikes in England; and yet not a single toll is exacted from the traveller. Each landlord is obliged to keep in repair a certain part of the road in proportion to his property; and for the purpose of ascertaining their respective portions, small pieces of wood or stone marked with numbers and capital letters are placed at different distances on each side of the way." "Such indeed are their goodness throughout the whole country, that during several thousand miles which I travelled in this and my former tour in 1779, I scarcely met with fifty miles that deserved the appellation of indifferent. They are also as pleasant as they are good, and in many places look like gravel walks carried through gentlemen's grounds and plantations, as they wind through the fields and extensive forests, the lofty trees casting a gloomy shade with their overhanging foliage." (Coxe, vol. v. p. 65). These observations have been confirmed by more recent travellers. Sweden, in truth, has been gradually making improvements in the departments in question, especially in the eastern and southern divisions of the kingdom, and she already is incomparably superior to Norway, Denmark, and Russia, and is not much inferior to the most civilized countries of Europe.

When treating of internal communication, and of the state of roads, the transition is easy to the consideration of the modes of travelling that obtain. Nor is less praise due here than on the former head. There is no regular supply of post horses kept, except in those places where the thoroughfare is very great: but they may at once be had by a traveller sending forward a peasant to bespeak them. The usual mode of supplying such horses may be explained in a few words. Horses are supplied by the country people in proportion to the quantity of land they rent; most persons generally send one or more horses to the nearest post-house, where they remain twenty-four hours; during which time, if employed, compensation is of course obtained, but, if otherwise, no remuneration is received. Travelling is unusually cheap, because one-half only of the charge is paid by the hirer, the other being defrayed in the shape of a tax, by the landholders. "I found," says Coxe, "travelling so exceedingly cheap in Sweden, that during a course of 500 miles, my whole expenses, including the prime cost of my cart, the hire of post-horses, the gratuities to the drivers, and the accommodations on the road, did not amount to 20*l.*, the drivers being the peasants themselves, who usually attend with their own horses, and are contented with a small acknowledgment of about 2*d.* or 3*d.* for each post. The horses are small, but lively and active, and they generally went at the rate of six or seven miles in an hour." (vol. iv. p. 349-50). "To Sweden," says Mr. Conway, "I give the travelling premium over every other country. I may still farther state that the traveller is in no danger of being imposed upon; and he will everywhere find clean inns, passably good fare, cheap bills, and civil people." (p. 286).

A country that can boast of such advantages in regard to internal communication possesses great facilities for general amelioration. At least without such advantages few steps can be taken in the career of improvement. Nor can it be denied that Sweden has availed herself in an eminent degree of the facilities she enjoys. The soil, in general, is not propitious; not more than a 20th part is arable, and not more than the half of that portion has actually been cultivated. But agriculture has done what could be effected under such circumstances. Husbandry in Sweden has been pronounced superior to what prevails in Denmark and even in Germany, and it is daily making rapid progress. as the quantity of corn raised is still not equal to the demand. A considerable quantity of corn, however, is made use of in the distillation of malt spirits: Hence they not only import from other countries, but it is not unusual with the poorer classes, in order to supply the deficiency, to mix with their flour or meal the inner rhind of the fir tree or the roots of certain bog plants. But the alternative will not long be necessary; for the southern and middle provinces, where agriculture has been very assiduously attended to, and where it has been brought to great perfection, produce wheat, rye, oats, hops, beans and pease, hemp, flax, in considerable luxuriance. The cultivation of potatoes having of late been introduced, that root is rapidly supplying the deficiency

* A full account of the inland navigation of Sweden is given in our article NAVIGATION INLAND.

occasioned by the limited quantity of corn. It has been stated that during the space of ten successive years, one harvest fails, two are scanty, five are moderate, and two are abundant; a proportion not much inferior to that of more southern countries, and of milder climates. The wheat and rye are sown in the middle of August, and are reaped in the same month of the following year. Barley and oats are consigned to the ground in spring, immediately on the melting of the snow: the former is cut down towards the end of August; the latter about the middle of September.

Among the various vegetable productions of Sweden, those of its forest are by far the most prominent and important. No less than one-third of the superficial extent of the whole country is covered with wood. These forests contain birch, poplar, mountain-ash, alder, pine, and fir. Dalecarlia, now called Falun, abounds more with such forests than any other province; and the numerous lakes are skirted with wood even to the margin of the water. Timber, as may be inferred, is one of the chief exports of Sweden; though by far the greater part of the houses, of the middle and lower classes, are composed wholly or chiefly of wood, and the same article is almost used throughout the whole kingdom for fuel. The wood and plants of Sweden differ in truth very little from those used in Britain, except some trees, as mentioned under the head *climate*, do not succeed in the former country beyond a certain degree of latitude; a remark which is applicable also to some plants, such as broom, firs, the walnut-tree, &c. Some indeed of the plants found in Sweden are not unknown in central Europe: the lichen of Lapland is frequently found on the plains at the 54th degree. The lichen rangiferinus, or rein-deer lichen or white moss abounds throughout the whole extent of Lapland, the chief support of the animal whose name it bears. The sagacious animal discovers it when covered with snow by the peculiar acuteness of its smell.

A remark, similar to that just made respecting the vegetable productions of Sweden, is applicable to the animals of that country; namely, that they differ extremely little from those of Britain. Horses, oxen, cows, sheep, differ only in this, that in Sweden they are of considerably inferior size; the consequence, it is likely, of poorer pastures, and of the comparative want of skill, and deficiency of capital on the part of the agriculturists. Goats and pigs are not very abundant. Hares and foxes seem equally common in the two countries referred to. There are, however, various animals, such as the lynx, the wolf, the beaver, the glutton, that are unknown in Britain. Of these the rein-deer is the most remarkable and celebrated. This animal resembles a stag, but is stronger; its antlers are stronger and more branched than those of the latter animal, and they also decorate the brows of the female. It is the camel of the north, the deep division of its hoofs being calculated for travelling over a snowy surface. The sledge, drawn by this animal, is extremely light, and covered underneath with deer-skin, in order to slide easily on the frozen snow. They easily accomplish 30 miles without halting, at the rate of 4 miles an hour; they can travel this distance without food; but they occasionally moisten their mouth in the snow as they proceed. This mode of conveyance, it is evident, can be performed only in winter when the snow is glazed over with ice. In the birds of Sweden there is little or nothing peculiar; nearly the same species abounds here that obtains in our own island. A similar observation is applicable to fish, which is very abundant, both along the sea-coast, and in the rivers and lakes. Leeches are peculiarly abundant, and form an article of export to this country. On the coast of the Baltic the stæmming is found, a species of herring peculiar to that sea.

In nothing is Sweden more celebrated than for its mines and mineral productions, including gold, silver, copper, iron, lead, marble, cobalt, zinc, coal, alum, and several precious stones. The average produce of the principal metals has been estimated as follows: 64 oz. of gold, 13,000 oz. of silver, 24,800 quintals of copper, 100,000 tons of iron, 431 quintals of lead, 22,000 quintals of alum, 35,000 tons of coal.* There are only two inconsiderable gold mines, of which the most important is at Adelfors, in the province of Smaland, discovered in 1737; but it seems to be nearly exhausted. With the exception of some silver veins discovered in Swedish Lapland, a mine of that metal at Salberg, thirty miles west of Upsal, is the only one known in Sweden. It contains about a hundred veins. Copper is found in various places, but the chief mines of this metal, which are in the province of Dalecarlia, have been wrought from time immemorial. The metal is not found in veins, but in great masses, and does not extend more than an English mile in circumference. The matrix of the ore is the saxum of Linnaeus, or rock and pyrites of iron. The richest part of the ore has been supposed to yield 20 per cent of copper; but as the poor and rich are blended, they average only 2 per cent. when brought from the mine, and 12 when smelted. The mine is private property, and is divided into shares. 1200 workmen are employed, namely 600 miners, and the same number in roasting and smelting the ore above ground. The mouth or opening of the mine, says Mr. Coxe, is extremely large, perhaps the largest in the world, being 1200 feet in diameter, or nearly three-quarters of an English mile in circumference; an immense chasm gradually enlarged to its present size by the excavations and frequent downfalls of the rock. The perpendicular depth is 1020 feet. But Sweden is most distinguished for its mines of iron. Those of Danemora, discovered in 1488, are particularly celebrated both for the abundance and for the superiority of that metal, called in England Oregrund iron, being exported thither from a part of that name where the Gulf of Bothnia joins the Atlantic. The pits are deep excavations, like gravel pits, and form so many abysses or gulfs. They, therefore, have no galleries, but are wrought in the open air. The richest ore yields

* The coal mines are not wrought to any great extent, from the quantity of timber used for fuel.

70 per cent of iron, the poorest 30; the collective mass averages one third of pure mineral. The number of miners in Sweden in 1825 amounted to no fewer than 28,256, including manufacturers, of which last the number is only about 6000.

Of the vast quantity of iron produced from the mines, about a fourth part is made use of at home, the rest being exported chiefly in the form of bar-iron and steel. There are large foundries for cannon and other pieces of artillery, as also works for making muskets and other small arms. The manufactures of copper and brass occupy very few hands. The manufactures, indeed, of Sweden are neither numerous nor important. From the superabundance of excellent timber, ship-building forms a most extensive and lucrative employment; and vessels of every species are sent from Swedish ports to many countries, particularly to those of South America. The other manufactures of the country are comparatively inconsiderable, and are carried on, not for exportation, but for family use. The true nature of division of labour is not well understood, or rather such division cannot in a poor and thinly inhabited country, such as Sweden, be carried very fully into effect; the Swedish peasantry make at home the clothing and utensils required for domestic purposes.

The foreign trade of Sweden has not of late been in so favourable a condition as it was twenty years ago, and previously to that time. Exports of iron and timber, which were her two most flourishing branches, have decreased to a great degree. The mines of Danemora have not of late been so productive; and the recent great extension of the iron mines of England has lessened the demand, as in England the inexhaustible stores of coal, and the ready command of inland navigation, are gradually rendering it independent of supplies from Sweden. With regard to the timber trade, the arbitrary restrictions which we have imposed on it, in order to give an advantage in this trade to Canada, have diminished, or almost annihilated our imports from the Baltic. Iron and timber, however, still form the staple exports of Sweden; the export consists of copper, pitch, tar, hemp, tallow, hides, saltpetre and alum. The chief imports are corn, wine, brandy, cotton, both raw and manufactured, silk, drugs, sugar, coffee, and other tropical products. In 1781, Mr. Coxe found the value of exports from Sweden to be L. 1,368,830 13s. 5d. and the imports to be L.1,008,392 12s. 4½d. In 1825, the tonnage of vessels trading between Great Britain and Sweden, entered inward and outward, was 104,968. *Chronol. Records of the British Royal and Commer. Navy*, by Cesar Moreau, p. 81.) Such tonnage was much less for the preceding nine years; but in 1814, it amounted to 180,755, and in the succeeding year to 167,112. Since 1825, we presume it has fallen considerably, owing to our diminished imports of iron and timber. This diminution of foreign demand for the products of Sweden is sufficient to account for the less rapid increase of population which has taken place there within the last four years.

The doctrines and ecclesiastical opinions, promulgated and enforced by Luther, were introduced into Sweden in the beginning of the 16th century. The Bible was soon after translated into the language of the country by Laurentius Petri, the first protestant arch-bishop of Upsal, who died at an advanced age in the year 1570. Several of the Swedish kings, particularly Gustavus Adolphus, who has been honoured with the appellation of Bulwark of the Protestant faith, have made most signal exertions for the maintenance of the reformed doctrines; and the Roman Catholic religion, which the Swedes regard with great abhorrence, has long been banished from the kingdom. Till the end of last century, when all religious intolerance was abolished by law, it would not have been safe for a Catholic priest to have made his appearance openly in the provincial districts of Sweden. The established church resembles that of England; and though some particular sectaries are to be found, they are far from being numerous or important.* It consists of one archbishop, whose see is that of Upsal, and eleven bishops, with several archdeacons. The whole number of clergy amounted in 1825, to 3,476. They are supported by the usual tithes; and their condition is very respectable. The parishes amounted to 2537, of which some, like the thinly inhabited parishes in the highlands of Scotland, are very large. There is one 150 miles in length by 48 in width. In Lapland some of the inhabitants are a journey of three miles distant from any place of worship. A convocation of the clergy virtually elects the prelates, by presenting the names of three to the king, of whom he must nominate one. Some of the parishes are under royal patronage; others are in the gift of private individuals, while some are consistorial, the clergyman being appointed by the votes of his brethren.

Of the literature of Sweden, though it was not brought to much perfection till about the middle of the 17th century, we can speak in terms of high commendation; indeed, in few countries in Europe has this important subject been more assiduously attended to. It is a rare occurrence to meet with a Swede, however low in rank, unable to read, education being there as generally diffused as in Scotland or Switzerland. A law, in truth, exists, declaring that every person, whether male or female, in the kingdom should be taught this necessary accomplishment. The number of public instructors paid by government in 1825, was 968, in addition to at least an equal number whose remuneration is obtained solely from their employers. Orders have recently been given by the king to establish schools on the Lancasterian system. Government, indeed, is doing all in its power to introduce improvements in teaching; and pays no less than L. 60,000 annually, in the shape of salaries, allowances to the poorer students, &c. The clergy take all seminaries of learning, particularly schools, under their particular jurisdiction, and labour by liberal attention to promote the object which such institutions have in view.

* The number of Jews is only 450, being more than a half less than are to be found in any other country in Europe.

Sweden can boast of two universities, those of Upsal and Lund. Of 1426 students who were attending the former in 1827-8, 126 are of noble rank; 332 are sons of clergymen; 227 sons of burghers; 226 of civil officers, not noble; 87 of military officers, not noble; and 207 of other persons of rank. The university of Lund is attended by 631 students in nearly the same proportions. In addition to these more dignified seminaries, there are twelve *gymnasia*, which latter are meant as intermediate between schools and colleges. The number of academies for the promotion of sciences amounts to twelve, all of which publish transactions, and of which those of Stockholm, Gottenburg, and Upsal are the most celebrated. A society of antiquaries was founded so far back as the year 1668; a medical society twenty years afterwards; the royal society of Upsal in 1720; and the royal academy of sciences in 1739. In 1753, an academy was instituted for the investigation of the language, history, and poetry of Sweden. Sweden can boast of some names that have obtained an eminent place in the literary, but particularly the scientific history of Europe. Queen Christina, in the 17th century, encouraged Grotius, Descartes, and other celebrated writers, to reside in her dominions. And though some of these distinguished persons did not remain long in Sweden; yet continued so long as to sow the seeds of science and literature, and to diffuse a taste for intellectual pursuits. The impulse thus given to the cause of letters, has since, though with some exceptions, been steadily promoted by government. In natural history, Sweden can exhibit the names of Linnaeus, Scheele, Tilas, Wallering, Quist, Cronstedt, Bergman. In history, Dalin and Laderbring have highly distinguished themselves. In remote times, John and Olaus Magnus rose to eminence as writers in the same department; but their works are too fabulous to be deserving of much attention. In lexicography, the name of Oehrling is well known. Baron Swedenborg, though eminent both in science and general literature, is better known as a theological writer, and as the founder of a sect that bears his name. The study of the Belles-Lettres has not been neglected, particularly in recent times, and it promises ere long to be very successfully cultivated. New publications amount to between 300 and 400 annually, of which one fourth are translations.

The native language of Sweden, which superseded that of the Fins, the original inhabitants, is a a dialect of the Gothic. "The Danes, Swedes, and Norwegians," says Dr. Murray, "are the posterity of the Teutonic or German tribes. They all speak varieties of one original dialect, of which the purest specimen is found in the Edda, a collection of mythological poems made in Iceland about the year 1120. The general character of this dialect is great purity of terms as to signification, certain peculiarities of inflection, which have arisen from the operation of time on a language long separated from the cognate dialects of Germany, and a curtailed or abbreviated form of many words. As to the figure of the words and their inflections, it is much more corrupted than the Saxon, the Alamannic, or even the modern German. The Scandinavian appears to have been a distinct dialect long separated from the German, so far back as the time of Jornandes, in the year 540."—(*Hist. of European Language*, ii. 479.) This language is spoken in its greatest purity in Dalecarlia. In the southern parts of the kingdom, several German and French words and expressions have been incorporated with the vernacular tongue; while in Lapland, the Finnist, or the language of the original inhabitants, still predominates.

The national character of the Swedes is highly respectable and interesting. They are remarkable for great simplicity both in manner, in dress, and in feeling. They are eminently hospitable, honest, contented, industrious, brave. The population being thinly scattered, and communication with strangers not being very frequent, they, like the Scottish Highlanders and the Welch, are attached to ancient usages, and traditionary legends; and their tendency in this respect is found to be considerably inveterate, not being easily removed or modified by recent improvement. The weakest point in their character, however, is an immoderate indulgence in the use of ardent spirits. This indulgence is confined chiefly to the lower orders: a considerable quantity of corn is made use of every year for the purpose of distillation. But with this trifling exception the character of the Swedes is entitled to the highest commendation. The following extracts contain much interesting matter respecting both the character and condition of this people, and though long, would lose much of their value by being abridged or changed. "Upon entering a cottage," says Mr. Coxe, "I usually found all the family employed in carding flax, spinning thread, and in weaving coarse linen, and sometimes cloth. The peasants are excellent contrivers, and apply the coarsest materials to some useful purpose. They twist ropes from swine's bristles, horses' manes, and bark of trees, and use eel skins for bridles. Their food principally consists of salted flesh and fish, eggs, milk, and hard bread. At Michaelmas they usually kill their cattle, and salt them for the ensuing winter and spring. Twice in the year they bake their bread in large round cakes, which are strung upon files of sticks, and suspended close to the ceilings of the cottage. They are so hard as to be occasionally broken with a hatchet, but are not unpleasant. The peasants use beer for their common drink, and are much addicted to malt spirits. In the districts towards the western coast, and at no great distance inland, tea and coffee are not unusually found, which are procured in great plenty, and at a cheap rate, from Gottenburg.

The peasants are well clad, in strong cloth of their own weaving. Their cottages, though built of wood, and only of one story, are comfortable and commodious. The room in which the family sleep is provided with ranges of beds in tiers, one above the other: upon the wooden testers of the beds in which the women lie, are placed others for the reception of the men, to which they ascend by means of ladders. To a person who has just quitted Germany and been accustomed to tolerable inns, the Swedish cottages may perhaps appear miserable hovels: to me, who had been long used to places of far inferior accommodation, they seemed almost palaces. The traveller is able to procure many conveniences, and particularly a separate room from that inhabited by the family, which could seldom be obtained in the Polish and Russian villages. During my course through those two countries, a bed was a phenomenon which seldom occurred, excepting in the large towns, and even then not always completely equipped: but the poorest huts of Sweden were never deficient in this article of comfort,—an evident proof that the Swedish peasants are more civilized than those of Poland and Russia." (*Travels*, iv. 333-5.)

"My journey from Undevalla," says Mr. Conway, "was made on a Sunday; and judging from the concourse of people who thronged the road, and particularly from the multitude assembled in a churchyard, which lay close to it, I had every reason to conclude that the Swedes are a church-going people. * * * I was exceedingly pleased with the respectable appearance of the peasantry. I know they are poor, wretchedly poor, but they had neither forgotten the way to the house of God, nor omitted in their poverty to provide decent apparel for their appearance there. * * * From a height over which the road passed in the course of this day's journey, I counted no fewer than eleven churches in sight at the same time. From other specimens than that which I have mentioned, I have no reason to doubt of their being all well filled." (*Personal Narrative*, 286-7.)

The following extract, which shall be the last, is still more interesting. "In passing along the Swedish roads," continues the same sensible writer, "the traveller frequently sees a charity-box fixed at the way side; and it is a beautiful trait in the character of that nation, worth all their records of glory and deeds of arms, that there is no instance of one of these boxes being plundered. The poor in Sweden are well provided for, both by these receptacles for casual alms-offerings, and by a regular parish provision; but to recur to the honesty of the Swedes. I think it may safely be averred that Sweden is the most remarkable of any of the European nations. On account of this virtue, doors are constantly left upon the latch. Horse stealing and sheep stealing are utterly unknown. Of sacrilege there is no example upon record; and indeed, excepting at Stockholm and Gottenburg, where a taint of foreign manners may be expected to obtain, every description of property may be considered as safe from dishonesty. (Ib. ib.)

With regard to the condition of the Laplanders Mr. Coxe observes, "the people are partly settled, and in part wild and roving; the latter live in tents made with coarse cloth; the former are fixed in small villages near the lakes, and chiefly follow fishing.* They build their cottages somewhat in the shape of a cone; and they are all constructed of wood. In summer their clothes are made of coarse cloth; in winter of the skins of rein-deer. In spring their food consists principally of the eggs of water-fowl, which are extremely plentiful in those parts; in summer and autumn, of the birds themselves, and of various others of the partridge tribe; and in winter, of the milk and flesh of the rein-deer and dried fish. Bread, which till lately was totally unknown to them, now makes a part of their usual diet. The Laplanders before their conversion to Christianity, possessed no books or MSS. though they knew many traditional histories and songs of ancient heroes and princes who once ruled over them, involved, however, in great uncertainty, and mixed with the most fabulous accounts." (iv. 61-4.)

The revenue of Sweden, though comparatively small in regard to that of other countries, is equal to the expenditure. It is little more than one million sterling. In England every individual is calculated to contribute to the revenue of the country L.3, 13s. 4d.; whereas in Sweden so small a sum as 9s. is the average individual contribution. The national debt, some years ago, amounted to L.6,000,-000, due chiefly to bankers and merchants in Hamburg; it has since been gradually reduced to L.1,380,000, owing entirely to Swedish subjects, and, it is thought, may be paid off by the operation of a sinking fund in fourteen years.

With an income and expenditure so small, the military and naval force cannot be supposed to be great. The military force, though never very great, has been extremely variable. The troops which crossed the Baltic along with Gustavus Adolphus, did not exceed 10,000 men, of whom the greater part were mercenaries. It has since that time amounted to 50,000, with 30,000 of reserve. At present, in a time of peace, it is very much reduced, consisting of 31,000, including both infantry and cavalry. There is, in addition to the regular army, a national force or militia, which is always maintained in an efficient state, and which is composed of about 20,000 men. The naval force has of late been much neglected. In 1799, there were twenty sail of the line; in 1806, thirty; and at present there are only six, and eight or ten frigates. There is, however, a considerable number of gunboats, and other flotilla calculated to convey land forces. The number of marines of all kinds is 10,000.

The government of Sweden, like that of Britain, is a limited monarchy, declared hereditary in the male line of the reigning family, but in case of a failure of male heirs in that line, a successor is to be nominated by the king, with the consent of the people. The civil list for the maintenance of the king and his household is about L.50,000; that of the crown prince, or king's eldest son, a third of that sum. The legislature consists of four classes, those of the nobles and landholders, of the clergy, of the deputies of towns, and of the peasants. Each of these classes has a speaker; the archbishop of Upsal being officially the speaker of the class to which he belongs, while the others are nominated by the crown. The king has a *veto* on the enact-

* Swedish Lapland contains 1,921 inhabitants, of whom 931 have flocks of rein-deer; 379 lead a wandering life. (*Revue Encyclopedique*, for February 1829, p. 374.)

ments of the legislature, but no bill can pass till it has received the sanction of three out of the four classes. The introduction of a bill, or a motion for a new law, as in Britain, may be made by any member, as well as by a minister of the crown. The diet which these classes form must meet by law every fifth year, but oftener, if convened by the king. Their power and privileges are similar to those of the British Parliament. The executive administration also resembles very much that of England; each department having its own board or head; in this department of government, division of labour has been carried to a very laudable extent.

Sweden possesses only one small colony, viz. that of St. Bartholomew, an island in the West Indies, about fifteen miles in circumference, ceded to Sweden by France in 1783.

On the history of this country we do not intend to enter minutely, as it has already been given collaterally under the articles BRITAIN, DENMARK, POLAND, RUSSIA; to which we refer the reader. Of its ancient state little is known with certainty. The original inhabitants were a colony of Finns from the banks of the Volga, and the vicinity of Mount Caucasus. And about three hundred years before the Christian era, they were driven from their northern settlements by the Teutones, a people who came thither from Germany, and who either expelled the original inhabitants, or became incorporated with them. Except in the northern extremity of Lapland, however, every trace of the Finns has long been obliterated. The present Swedes, therefore, as well as the Danes and Norwegians, are of Teutonic or Gothic origin; and the term Scandinavia, or Land of Caves, was conferred on the extensive regions which now form these three nations, from the practice of the inhabitants dwelling in rocky caverns. (Jornandes *de rebus Geticis*, c. 3. Murray's *European Languages*, i. 12, 153; ii. 478).

This country was not converted to Christianity till the end of the eleventh century, when this happy event took place by means of missionaries from England. It renounced the errors of popery, and adopted the reformed doctrines, five centuries afterwards. Sweden, though meanwhile it had various forms of government at different periods, remained free till the year 1392, when Margaret, queen of Denmark, styled the Semiramis of the north, conquered it by policy and by force of arms, and made one kingdom of these three vast states. This conquest was not destined to be permanent. Sweden was the victim of wars and insurrections; and was alternately free and enslaved for upwards of a century; at the end of which time appeared Gustavus Vaza, a young man, descended from the ancient kings of the country; and, abandoning the forests of Delecarlia, where he had concealed himself, he aspired to become the deliverer of Sweden. His attempt was successful; the Danes were expelled, and Gustavus was himself elected king of the country of which he had been the liberator. He introduced the reformation into Sweden; and was in many respects a man superior to his age. He had the influence to get the crown declared hereditary in his family, who, with various degrees of eminence and merit, have continued till within these few years to enjoy it. He died in 1560, after a glorious reign of thirty-seven years. Anxious to strengthen the throne by an alliance with the family of some of the neighbouring powers, he endeavoured to accomplish that object by the marriage of his son Eric, who succeeded him, to Elizabeth queen of England. The offer, as is well known, was rejected.

The successors of this enlightened restorer of Swedish liberty were, with few exceptions, not worthy of him. They were all indeed endued with a chivalry and heroism not common even in ages when such attributes were regarded as the perfection of character; but they were devoid of sober judgment, of nice discrimination, and of sound policy. Their romantic spirit and enterprizes, as in the case of Charles XII. not unfrequently approached to the verge of infatuation or insanity; and tended directly to retard the progress of knowledge and civilization in the territories over which they ruled.

Of the descendants of Vaza, Gustavus Adolphus, on whom has been conferred the title of Great, was the most distinguished, and to whom we have already alluded in this article as the bulwark of the Protestant faith. He defended the Lutherans against the Emperor with equal bravery and good fortune. He made war, with success and with consummate skill, against Russia, Denmark, Poland, and Germany, and these great achievements he performed before he had completed his thirty-seventh year; at which age he fell in the arms of victory at Lutzen; carrying "to the tomb," says Voltaire, "the name of Great, the regrets of the north, and the esteem of his enemies."*

He was succeeded by his daughter, Christina, to whom we have before referred as a great patroness of learning and learned men. She became a Catholic; and relinquishing her crown, retired at the age of thirty-seven to Rome, where she passed the remainder of her life in the centre of the arts which she loved, and for which she had renounced sovereignty.

The history of Charles XII., who has not inaptly been called "an illustrious madman,"—his successive victories over the Danes, the Poles, the Russians, his ultimate defeat at Pultowa, his confinement in Turkey, his escape, and his death at the siege of Frederickshall, are well known to every reader, and need not to be told here. Nor is it necessary to enter on the history of any of his successors. The extensive conquests which Sweden had made beyond the Baltic were gradually taken from her during the course of the last century. The late Gustavus IV., on the French revolution, entered into an alliance with Great Britain against

* Gustavus Adolphus had the discrimination to commit the management of the government to the illustrious Axel Oxerstiern, one of the great statesmen of Europe, and who enjoyed the confidence of three successive Swedish monarchs. He died in 1651. His nephew, Benedict Oxerstiern, was scarcely less celebrated. He held offices of dignity and responsibility under four successive monarchs, and died Chancellor in 1702.

France; and when, in 1808, Russia joined her forces to those of the latter kingdom, he broke off an alliance with that power; and on the invasion of his territories by the Russians, lost Finland, which has since (1809), continued dissevered from Sweden. The result of this war was not merely this loss, but the dislike of his people, and resentment of the nobles. The Duke of Sundermania, who was at the head of the discontented party, conceived and executed the plan of dethroning Gustavus, and of investing himself with his honours. This was easily effected: not the least disturbance took place on account of it; and the Duke assumed the crown under the title of Charles XIII.

Charles changed the government from a despotic to a limited monarchy. He made peace with Russia. He joined himself to the allies against France. By a treaty made in 1814, and confirmed in the subsequent year at the congress of Vienna, Norway was added to his dominions, on condition of his ceding to Prussia Pomerania and the island of Rugen: Finland was finally guaranteed to Russia; and Sweden was confined within the bounds which we have already described. It may here be mentioned, that when Norway was united to the country which we are describing, her independence, as to government, laws, and institutions, was solemnly stipulated: a full account of which may be found under the article Norway. Meanwhile, in 1810, General Bernadotte, a Frenchman, had the influence to get himself declared Crown-prince of Sweden; a choice which, though at first it excited general surprise, has proved very judicious, from the prudent and liberal character of that celebrated person. In 1818 Charles XIII. died, and Bernadotte quietly ascended the throne, under the title of Charles XIV. This monarch has indeed shown himself worthy of the dignity conferred on him. He has patronized and promoted, as previously stated, every species of internal improvement. He has constructed canals, erected schools, and done all in his power to promote the cause of education. A new civil and penal code is in progress. The public hospitals have not been overlooked; six useless ones have been suppressed; every modern improvement or discovery is immediately introduced. And, under his enlightened sway, Sweden, though, from inherent physical causes, she can never rise higher than a power of the second order, is rapidly advancing in real prosperity and influence, and is affording an example of improvement and of enlightened policy, which many nations more highly favoured in point of climate and physical advantages, would do well to imitate.

See *Travels* by Coxe, Wraxall, Thomson, Conway, Brooke, Rae Wilson; *Revue Encyclopedique* for Feb. 1829. Cantzler. *Mem. sur les Affaires Polit. et Econ. de Swede;* also the works of Puffendorf, Vertot, and Voltaire, respecting Sweden. *Edin. Annual Register* for 1815.

SWEDENBORG, Emanuel. This eminent and most remarkable man was born at Stockholm, in Sweden, Jan. 29, 1689, and died in the city of London, March 29, 1772. His father, Jesper Swedberg was Bishop of Skara, in West Gothland. and superintendent of the Swedish mission in England and America, a man of extensive learning and great piety. In the year 1719, Emanuel Swedberg, on account of his learning and usefulness, was elevated to the order of nobles, and his name was then changed to that of Swedenborg. He was educated at the University of Upsal, and was even in his youth remarkable for his application and assiduity in the study of philosophy, mathematics, natural history, chemistry and anatomy, together with the ancient and modern languages. Although even in youth he was seriously disposed, and thought much on religious subjects, yet he says he was by Divine Providence kept from reading dogmatic and systematic theology; and it was not until the latter part of his life that he learned the Hebrew language, in order to study the scriptures. He was thus, he says, prevented from imbibing the unfounded opinions and inventions of men. In 1716, at the age of 28, Swedenborg was appointed by Charles XII. Assessor Extraordinary of his Board of Mines. The diploma appointing him to the office states "that the king had a particular regard to the knowledge of mechanics possessed by Swedenborg:" and in Dr. Norberg's history of that monarch, many interesting conversations are related between Swedenborg and Charles.

From 1716 to 1720, Swedenborg's time was principally spent in travelling. He visited the Universities of England, Holland, France and Germany. In 1721 he undertook a scientific journey for the purpose of visiting the mines and smelting works of Europe. During this journey he became acquainted with the Duke of Brunswick, who published, at his own expense, Swedenborg's Opera Philosophica et Mineralia, in three volumes. The first volume is entitled "Principles of Natural Things, or New Attempts at a Philosophical Explanation of the Phenomena of the Elementary World." This volume is divided into three parts: the *first* treats of creation in general; the *second* treats on magnetism and the variations of the magnetic needle; the *third* treats of the sun and its vortex, of the creation of the planetary earths from the sun, of Paradise and the first man. He here mentions *seven primary planets;* this discovery being more than 40 years before Dr. Herschel. The 2d volume of this work is entitled, "The Subterranean or Mineral Kingdom, or a Treatise on Iron, and the methods which are adopted in various parts of Europe for the liquefaction of iron and converting it into steel, &c." The 3d is entitled "The Subterranean or Mineral Kingdom, or a treatise on copper, and brass, &c."

In 1740 he published "Œconomia Regni Animalis; the Economy of the Animal Kingdom." The first part treats of the Blood, the Arteries, the Veins, and the Heart; with an Introduction to Rational Psychology. The 2d part treats of the motion of the brain, of the cortical substance, and of the human soul.

In 1744-5, he published "Regnum Animale." The first part of this work treats of the viscera of the abdomen, or the organs of the lower regions. The 2d part, of the viscera of the breast, or of the organs of the superior region. The 3d part treats of the skin, the touch, and the taste, and of organical forms in general. In these works, Œconomia and Regnum Animale, he made many important discoveries in anatomy and in the circulation of the blood, and which have been attributed to more modern authors. It was Swedenborg who first discovered the existence of a passage of communication between the two lateral ventricles of the cerebrum. The above works are the principal philosophical writings of Swedenborg. There are minor ones, of which it is not necessary to take notice.

In the year 1743, at the age of 54 years, Swedenborg declared that he was gifted with spiritual illumination, and was called by the Lord to open to men the spiritual sense of the Holy Word; and thus be the means of instituting a New Church, signified by the New Jerusalem in Revelation.

In a letter from Swedenborg to the Duke of Hesse, he says, "in your gracious letter you ask how I attained to be in society with angels and spirits, and whether that privilege can be communicated from one person to another. Deign then to receive favorably this answer. The Lord, our Saviour, had foretold that he would come into the world: and that he would establish there a New Church. But as he cannot come again into the world in person, it was necessary he should do it by means of a man, who should not only receive the doctrine of this New Church in his understanding, but publish it by printing; and as the Lord had prepared me for this office from my infancy, he has manifested himself before me, his servant, and sent me to fill it. This took place in the year 1743. He afterwards opened the sight of my spirit, and thus introduced me into the spiritual world, and granted me to see the heavens and many of their wonders, and also the hells, and to speak with angels and spirits, and this continually for 27 years. I declare in all truth that such is the fact. This favour of the Lord in regard to me has only taken place for the sake of the New Church, the doctrine of which is contained in my writings. The gift of conversing with spirits cannot be transmitted from one person to another, unless the Lord open the spiritual sight of that person."

From the time he was thus called of the Lord he devoted all his time and substance to writing and printing his theological works. In order to have his works printed he travelled to Holland, France, and England. In this latter country he died on the 29th March 1772. The principal theological works of Swedenborg are the Arcana Cœlestia, in 12 vols. 8vo. True Christian Religion, 2 vols. 8vo. Heaven and Hell, one vol. 8vo. Conjugal Love, 1 vol. 8vo. Divine Providence, 1 vol. 8vo. Apocalypse Revealed, 2 vols. 8vo. Apocalypse Explained, 6 vols. 8vo. The Last Judgment, 1 vol. 8vo. Divine Love and Wisdom, 1 vol. 8vo. Besides these there are many smaller works; but they appear only intended as introductions to the others, or as abridgments of their contents. In these works the following doctrines are developed. 1. That there is but one God, one in essence and one in person, in whom there is a Divine Trinity like soul, body, and operation in man, and that the Lord and Saviour Jesus Christ is that one God. 2. That the humanity derived from the virgin was successively put off, and a Divine humanity put on in its stead: and this was the glorification of the son of man. 3. That redemption consisted in the subjugation of the powers of hell, whereby man was delivered from the bondage of evils and falses, and that it was thus an actual work on the part of the Lord, for the sake and happiness of man. 4. That faith alone does not justify and save man: but he must have faith, charity and good works, and thus, by the actual union of will and understanding, knowing, loving and doing the commandments, become regenerated. 5. That the sacred scripture or Word of God is divinely inspired in every particular, and contains a natural, spiritual, and celestial sense, and is thus applicable to angels in heaven, as well as to men on earth: and that the letter of the Word is in every part purely correspondential: and therefore the science of correspondence, or the analogy between natural and spiritual things, is the key whereby the Word is opened in its genuine spiritual sense. 6. That man enters immediately after death into the spiritual world, leaving his body, which will never be reassumed: and continues to all eternity a man in a human form, with the possession of all his faculties. Death is therefore a continuation of life: and according to man's prevailing love, such is his state hereafter. The love of the Lord and the neighbour constitutes heaven; and the love of self and the world constitutes hell: for heaven and hell are not places, but states. 7. That the last judgment spoken of in the New Testament, was effected by the Lord in the spiritual world in the year 1757; it being a judgment upon those in the world of spirits who had been of the former church: the good were then elevated to heaven, and the evil cast down into hell. Thus the way was prepared for the second advent of the Lord, which was a coming not in person but in the power and glory of his Holy Word, and a new spiritual influx being communicated, a New Church would thereby be established. This is signified by the old heaven and the old earth passing away, and the new heaven and the new earth being formed. These are the leading doctrines contained in Swedenborg's Theological Works. But three of his principal works are chiefly designed to explain the scriptures in the spiritual sense, and in these, together with several of his large works, there are interspersed, Memorable relations of things seen and heard in the heaven of angels and in the world of spirits. Swedenborg on all occasions unhesitatingly declared that he had intercourse with the spiritual world: and many facts are related by those personally acquainted with him to prove the truth of his assertion: but he himself always refers alone to the nature of his writings and the things contained in them as sufficient to prove to any one that he was so favoured of the Lord. A short time previous to his decease, he was asked by the Rev. Thomas Hartley, Rector of Wynwick, if all he had written was strictly true, he replied "I have written nothing but the truth as you will have it more and more confirmed hereafter all the days of your life; provided you always keep close to the Lord, and faithfully serve him alone, in shunning evils of all kinds as sins against him, and diligently searching his Word, which from beginning to end bears testimony to the truth of the doctrines I have delivered to the world." In a letter to the king of Sweden, Swedenborg says, "I have already informed your majesty, and beseech you to recal it to mind, that the Lord our Saviour manifested himself to me in a sensible personal appearance; that he has commanded me to write what has been already done and what I have still to do: that he was afterwards graciously pleased to endow me with the privilege of conversing with angels and spirits, and to be in fellowship with them. I have already declared this more than once to your majesty, in the presence of all the royal family, when they were graciously pleased to invite me to their table with five senators and several other persons; this was the only subject discoursed of during the repast. Of this I also spoke afterwards to several other senators; and more openly to Count de Tessin, Count Bonde and Count Hopken, who are still alive and were satisfied of the truth of it." During the life time of Swedenborg there were many eminent men in Europe, who gave credit to his mission and were the warm advocates of his doctrines. Among these may be mentioned Dr. Gabriel Andrew Beyer, Professor of Greek Literature and member of the Consistory at Gottenburg; Dr. Rosen, an eminent Clergyman of the same city; Mr. Robsam, Director of the Bank of Stockholm; Christopher Springer, Swedish Consul at the Port of London; Dr. Messiter, an eminent Physician in London; General Christian Tuxen of Elsineur, in Denmark; John Andrew Van Hopken, prime minister to the king and secretary to the Swedish Royal Academy of Sciences; Mr. Œttinger, Superintendent of the royal mines in Sweden; and the Rev. Thomas Heartly, Rector of Wynwick in Northamptonshire, England. All these gentlemen were personally and intimately acquainted with Swedenborg, and their letters &c. show their undoubting confidence in Swedenborg's spiritual communications. The receivers of his writings are considerable in Europe and America. All his theological works have been translated into English, and many of them into German and French. We will conclude this notice with an extract from a letter of Count Hopken to General Tuxen. "I have known Swedenborg for two and forty years, and sometime since daily frequented his company. A man who like me has lived long in the world, and even in an extensive career of his life, may have numerous opportunities of knowing men as to their virtues or vices, their weakness or strength; and in consequence thereof, I do not recollect to have ever known any man of more uniformly virtuous character than Swedenborg; always contented, never fretful or morose, although throughout his life his soul was occupied with sublime thoughts and speculations. He was a true philosopher and lived like one: he laboured diligently, lived frugally without sordidness; he travelled continually, and his travels cost him no more than if he had lived at home. He was gifted with a most happy genius and a fitness for every science, which made him shine in all those he embraced. He possessed a sound judgment upon all occasions; he saw every thing clearly, and expressed himself well on every subject." Roche.

SWEET SPRINGS, post village and watering place, situated in the northeastern part of Monroe county, Virginia, and on a mountain elevation of at least 2400 feet above the Atlantic tides; 84 miles NW. by W. from Lynchburg; 204 miles W. from Richmond; and 263 miles SW. by W. from W. C. These fountains are on the extreme higher southwestern sources of James river. Darby.

SWIFT, Jonathan, D. D. the illustrious Dean of St. Patrick's, was born in Dublin on the 30th of November 1667. The house, (No. 7, Hoey's Court) in which he first saw the light, is still pointed out with reverence. He was a posthumous child, his father, of the same name, who, among other employments, held the office of steward to the society of the King's Arms, having died eight months before the birth of his son. His mother was Abigail Ericke, of Leicestershire, a lady whose ancient genealogy was her principal dowry. On the death of her husband, our author's mother found herself left utterly destitute. She and her son were supported by the charity of their relations, some of whom were sufficiently wealthy. Under such circumstances, the subject of this sketch "early adopted," says Sir W. Scott, "the custom of observing his birth-day as a term, not of joy, but of sorrow, and of reading, when it annually occurred, the striking passage of Scripture, in which Job laments and execrates the day upon which it was said in his father's house 'that a man child was born.'"

In his infancy he resided for three years at Whitehaven with a nurse, who, out of fondness for the child, had taken him with her, when called to the town by the commands of a dying relation. This circumstance constitutes the foundation of the erroneous opinion that he was a native, not of Ireland, but of England. At the age of six, he was sent to the school of Kilkenny, where his name, cut in school-boy fashion upon the desk or form, is still shown to strangers. From Kilkenny he was removed to Trinity College, Dublin, in the year 1682, at the age of fourteen. At this seminary he was remarkable neither for studious habits, nor attention to the college discipline, nor for correctness of moral conduct. The truth is, he soon became notorious for great laxity of behaviour, and incurred the open displeasure, and had to submit to the censure of the heads of the college. He read and studied rather for amusement and to divert reflection, than with the zeal of acquiring knowledge His reading, however, though desultory, must have been varied and extensive, since he is said to have already drawn a rough sketch of the *Tale of a Tub*; which yet did not appear till the year 1704. Owing to his want of taste for logic, he was so ignorant of that science, reckoned at that time indispensable for an academical degree, that on examination he was found ignorant even of the necessary syllogistic forms, and obtained the degree of A. B. by *special favour;* a term used in the university to denote want of merit. He continued at college three years after procuring this title, and during that time he applied himself more assiduously to study, regularly devoting to it eight hours a day.

Meanwhile the death of Godwin Swift, his uncle, and principal supporter, caused him to leave college, after a residence there of seven years: when he paid a visit to his mother, who then lived at Leicester, to consult her about the future course of his life. Sir William Temple having married a relation of Mrs. Swift's, and having been long intimately acquainted with some members of Swift's family, he was recommended by his mother to that celebrated person for advice. Sir William received him with kindness; and, being pleased with his conversation and intelligence, detained him two years in his house, not as a dependent companion but as a confidential friend. Here he was introduced to the acquaintance of King William, whose friendship and confidence he gained. In the meantime he obtained the degree of A. M. from Oxford; and having had some misunderstanding with his patron, he forsook his house; and, going to Ireland, obtained orders and a curacy, through the secret influence, it is supposed, of the friend from whom he had parted. The curacy he soon after resigned, and returned to the roof of Sir William Temple, where he continued to reside till the death of this illustrious man: an event which Swift mentions in his Journal in the following terms: "He died at one o'clock this morning, (27th January 1698-9), and with him all that was good and amiable among men." Sir William bequeathed to him a small legacy in money, and entrusted him with the charge of his MSS., and, during his last illness, had warmly recommended him to the notice of the king. The MSS. were published under the superintendence of Swift, with a dedication to William. As our author was not immediately promoted by the court, or rather was overlooked, he relinquished the Revolution or Whig principles, which he had before entertained, and began to connect himself with the opposite party, to which he afterwards remained faithfully attached, and whose views he so powerfully promoted by his pen. He, ere long, though from a different quarter, obtained two livings in Ireland; and, in 1713, he was elevated to the deanery of St. Patrick's, Dublin, the highest preferment he ever gained. This situation he owed to his abilities, and to those talents for satire which he had enlisted so eagerly in the service of the administration, and which led him to those numerous political compositions, in prose and verse, which form such a considerable portion of his works.

On the death of Queen Anne, in 1714, and the triumph of that party from which he had withdrawn, he lived in retirement till the year 1720, when he gave to the world a political pamphlet, relative to Ireland, entitled, "*A Proposal for the universal use of Irish Linen.*" This work, while it gained him the enmity of the ministry, rendered him extremely popular in the eyes of his countrymen; and this popularity was further increased by his celebrated Letters, under the title of *M. B. Drapier*, published in 1724, and written with a view of opposing the introduction of Wood's copper coinage, the metal being so debased as to be worth only a third of its nominal value. "From this important era," says Johnson, "he was the oracle of the traders, and the idol of the rabble. The *Drapier* was a sign; the *Drapier* was a health; and which way soever the eye or the ear was turned, some tokens were found of the nation's gratitude to the *Drapier*."

His political reputation and his political influence were now very high. But he had not meanwhile neglected other studies of an elegant or miscellaneous nature; and, not to mention other publications, in 1727, appeared "*Gulliver's Travels;*" a production that was universally read and admired; and which does not seem to have lost any of the popularity which it so early obtained.

But amid his studies and his publications, another subject never ceased to engross a large share of his attention, and his name is connected in a most extraordinary manner with the tender passion. The story of Stella and Vanessa is known to every reader, and needs not to be repeated here. In this part of his life there is the same obstinacy and disregard to the proprieties of society that marked his character in every other respect. Both these ladies predeceased him: events which successively made a deep impression on his mind, and had a tendency to bring about that awful malady to which he had long been verging, and to which he at last fell a prey. The first stage of his disease was that of violent and furious lunacy. From this stage, aggravated by severe bodily suffering, he passed to that of perfect idiotcy. During the course of three years he is known to have spoken only once or twice. At length he died without a struggle, on the 19th of October 1745, in the 78th year of his age.

Swift was a man of original genius, of varied but not profound learning, of fine taste, of great talents for wit and satire, capricious in his friendship, charitable to the poor, not mindful of favours, whimsical, obstinate, misanthropic, avaricious. The best edition of his works is that recently published by Sir W. Scott, with an excellent Life prefixed. (T. M.)

SWIMMING is the art of suspending and sustaining the body in water, and of making motion either forward or in any direction, by means of the arms, legs, &c. This art, which is common to savage with civilized nations, and which must be nearly coeval with the formation of man, is understood only by a very few of those who practice it. Though with the Greek and Romans it was not unusual to characterize the uneducated by saying, *neque literas neque natare didicit*, yet swimming has very seldom been a regular branch in the education of youth.* All persons who practice this art, even those who excel in it the most, have been self-taught, and their eminence in it has been the result not of fixed rules, but of trial and perseverance.

Swimming, however, though the nature of it, and the principles on which it depends, have seldom been much attended to, is by no means a recondite or difficult art. The very contrary indeed may almost be said to be the case. The human body has been ascertained by experiment to be lighter than the same bulk of water; that is, the human body when immersed in water, displaces a quantity of that fluid heavier than itself. The body, therefore, when put in water, would necessarily float, if allowed to remain inactive. Mr. John Robertson, (*Philosophical Transactions*, vol. i, p. 30,) performed a variety of experiments on the gravity of the human body. He weighed ten different individuals, comparing their weight with the quantity of water displaced by their bodies, and the result was as follows:—"Excepting two, every man was lighter than his equal bulk of fresh water, and much more so than his equal bulk of salt water; consequently," he concludes, "could persons who fall into water have presence of mind enough to avoid the fright usual on such accidents, many might be preserved from drowning." Mr. Robertson, in illustration of his theory—and many similar illustrations might be given—mentions the case of a young man of thirteen, little acquainted with swimming, who, having fallen overboard from a vessel in a stormy sea, had presence of mind to turn immediately on his back, and thus remained a full half hour quietly floating on the surface of the water, when he was picked up.

Dr. Franklin's opinion on the gravity of the human body, when compared with water, is well known, and is most sound. He thinks that the solid parts of the human body, such as the legs, arms, head, are specifically somewhat heavier than fresh water, but lighter than salt; but that the trunk, particularly the upper part, from its hollowness, is so much lighter even than fresh water, that the whole of the body taken together is too light to sink wholly either in fresh or salt water. He says, that a body immersed in water would sink up to the eyes,† but "that, if the head be leaned back, so that the face looks upwards, all the back part of the face being then under water, and its weight consequently in a great measure supported by it, the face will remain above water quite free for breathing, will rise an inch higher every inspiration, and sink as much every expiration, but never so low as that the water may cover over the mouth." He states, besides, that clothes give little additional weight in the water, though when out of it, and drenched, the case is quite otherwise. The reason why a body sinks when drowning is, that the hollow part of the trunk, &c. being filled with water, the specific gravity of the body is so considerably increased, that it is weightier than the quantity of water it displaces.

Under such circumstances, if the equilibrium be not destroyed, the weightier parts of the human body would sink deepest in the water, while the contrary parts would continue on the surface, or not sink far below it. Owing to the buoyancy of the trunk, the upper part of the body is the lightest; for though the head is heavy, yet not so heavy as to counterbalance the trunk. The natural position, therefore, which, if the equilibrium be not interfered with, a body would assume in water, is that erect one which it obtains on land.

But the great difficulty is to maintain the equilibrium in question; to accomplish which nothing is so necessary as absence of fear, and the most complete self-command. A person should have a firm and sufficient conviction that the body, if left to itself, naturally floats, and that violent and irregular motion and struggling have a direct tendency to destroy this natural position. Indeed, the same struggling and throwing of the limbs which we see persons have recourse to in dangerous cases in the water, would, if practised on land, deprive the body of the faculty of locomotion, or of retaining its erect posture. Every swimmer knows that by keeping his body perfectly quiescent and upright, and by throwing his head back, so as to rest on the surface, his face will remain entirely above the water, and respiration will be as easy and free as if he were on land. It is mentioned, that when a sailor was thrown overboard, the captain, with great presence of mind, called out to him, "keep your hands down in the water." He obeyed the call; the head kept above the surface, and the due balance of the body was thus obtained. To acquire and to preserve this due balance of the body, the arms should indeed be extended laterally under the surface of the water, with the legs separated, the one stretched forward, the other backward. This position being obtained, motion backward or forward, or swimming, is to be learned gradually; indeed, it almost follows as a necessary consequence; and a very little practice will make a person a considerable adept in the art. In swimming forward, the body must be kept a little oblique, though the less so the better. The truth is, that the best swimmers maintain in water an attitude almost as erect as when they walk or run on land. The motion is produced by the motion of the arms and legs, which are extended and drawn in alternately. In swimming backward, the face requires to be uppermost, and while the motion forwards is made by the action of the arms and legs, the latter only is employed in backward motion, the hands being generally folded across the breast. There is yet another mode of swimming either backwards or forwards; and that is by treading as it is called, or by moving the feet only; by which a person seems to walk as on land.

* Oronzio di Bernardi, to whom we owe one of the best systematic works on swimming, was appointed to teach this art in the Royal Naval Academy of Naples.

† This opinion is corroborated by that of a very able writer in *The Quarterly Review*, who states, that "when the human body is immersed, one-tenth of its weight will remain above the water in salt, and one-eleventh in fresh." (No. 67, p. 38.)

In this mode, the body is nearly perpendicular, and the arms are generally folded, or the hands are clasped and held above water. "I know by experience," says Dr. Franklin, "that it is a great comfort to a swimmer, who has a considerable distance to go, to turn himself sometimes on his back, and to vary in other respects the means of procuring a progressive motion." Swimming on the back is also useful in cases of cramp in the leg,—an affection to which a person is often exposed, and which not unfrequently proves fatal. A good swimmer can easily resist the fatal effects of cramp, by turning immediately on his back and jerking the affected limb for a little in the air. But before recourse can be had to this remedy, one must be thoroughly devoid of fear, and be fully convinced that the natural tendency of the body is to float, it being lighter than the quantity of water it displaces. We may here observe, that in addition to the swimming backward or forward, there are many other fanciful positions and motions adopted by persons who are masters of the art and completely devoid of fear. In learning to swim, it may also be observed, recourse is often had to corks, bladders, planks, &c. But it is perfectly evident that such expedients are unnecessary: they are only used for the purpose of giving confidence in the power of the water to support the body; and the confidence, as shown above, can be more easily and more effectually obtained otherwise. Practice, without any of the auxiliaries referred to, will have more effect in teaching to swim than any other expedient whatever.

To a novice in the art, it is almost incredible to what perfection swimming can be brought. A good swimmer can urge himself forward by each stroke a distance equal to the length of his body. There are various ways of recruiting the strength in water by changing the position; and thirst and hunger are less severely felt than on land, owing it is probable to the quantity of the bracing liquid imbibed by the pores of the body. Under such circumstances a good swimmer can advance at the rate of three miles an hour, and continue for two or three hours in water. This, however, it is evident, must depend much on the temperature of water and on the climate. Persons have been known to perform the extraordinary distance of thirty miles at a stretch; and it is recorded that Nicolo Pesce, the famous Neapolitan diver, performed the incredible distance of fifty miles on the coast of Calabria. Nay, water had become so much like his native element that he is stated to have spent five successive days and nights in it with perfect impunity. Bernardi's pupils, on the eleventh day of their instruction, were able to accomplish an uninterrupted circuit of six miles.

Diving, or the power of descending either perpendicularly or obliquely under water, is a species of swimming to which we have not yet adverted. It is astonishing to what perfection it can be brought by practice. The inhabitants of Otaheite excel so much in this art, that when a nail is thrown into the sea, they can leap after it and catch it ere it gain the bottom. Pearls and shell fish, &c. are brought from the bottom of the sea by divers; and in ancient times divers were not unfrequently employed to destroy the ships of the enemy under water. Nor is it found to be a difficult feat. All good swimmers can dive less or more; but great correctness and eminence in it can be obtained only by daily practice. In springing from a height into the water, great precaution is required so to dispose the body as to avoid any unfavourable concussion from the water. To prevent the body from receiving injury from this concussion, the limbs should be kept firm together, the head protected by the hands clasped over it, so as to present a sharp edge, the body presenting the shape of an arrow, the hands and head entering first, the feet last. The eyes should always be kept open under water, by which every object can be discerned, and rocks and other interruptions avoided. For a very full account of this subject, we refer to the article Diving.

Many speculations have been entered into with regard to the relative natural aptitude of man for swimming compared to other animals. Man, we readily confess, labours under considerable inferiority in this respect, though by experience he can at length attain to much greater perfection in the art than many of the lower animals. Fish of all kinds possess natural facilities for swimming, such as the air-bladder, or bodies flat and thin, or long and flexible, assisted in every case by the fins, which latter are peculiar to them. Water indeed is the element natural to fish; and their form and structure are wisely adapted by providence for answering this purpose. The brute creation, though incomparably inferior to fish in this respect, are yet superior, at least during the first years of their existence, to the human race. They are, in the first place, incapable of fear, and in the second place, their head is exceedingly light in proportion to the rest of their body. It contains little brain, and it abounds in sinuses, so that its relative weight is so inconsiderable that they can easily keep their mouth and nose above water and respire freely. In man, on the contrary, the head, which is full of brains, and contains no cavities, is exceedingly heavy compared with the rest of the body: and the great difficulty which he experiences in swimming is to counteract this specific gravity and keep the organs of respiration above water. To attain this object is the perfection of swimming; and when it has been attained, man, though possessed of natural disadvantages, is superior to all animals, except fish, in this nice and useful art.

See the treatise of Bernardi, which has not yet appeared in an English form, but of which an excellent abstract, combined with much new matter, may be found in the *Quarterly Review*, No. 67. See also the *Philosophical Transactions* for 1757, No. 50; Dr. Franklin's *Essay on Swimming*, and *Thevenot L'art de Nager*. (T. M.)

SWINDEN, Van, J. H. a celebrated natural philosopher, was born at the Hague, on the 8th June 1746. His father, an eminent barrister, intended to bring up his son to the same profession, and with this view he watched his early education with the tenderest care. The young Van Swinden, however, soon showed a disposition to studies of a different kind; and he took peculiar delight in calculating, drawing, watch-making, and mechanical pursuits. At an early age he was sent to the university of Leyden, where he had the good fortune of meeting with Mr. Hennert, then private lecturer in Leyden, and a staunch Eulerian analyst, who initiated his friend into all the intricacies of the modern calculus.

At the early age of twenty (1767), when he was called to the chair of natural philosophy in the university of Franeker, he opened his lectures with a discourse, *De causis errorum in rebus philosophicis.*

At Franeker, the tranquillity of a small town gave full scope to his ardour for study. He would often not stir from home for weeks together, and all his time was divided between his closet, his pupils, and his observations. This overstraining of his faculties had its usual effects; his health was impaired, and the mineral waters of Spa, Aix-la-Chapelle, Pyrmont, were frequently resorted to, in order to restore his strength, and above all, to drive him from his studies.

The subjects of meteorology, electricity, and magnetism, then particularly engaged his attention; and he applied himself with unremitting zeal to such observations as were likely to throw some new light on these interesting subjects. Amongst his earliest writings, is his *Tentamen de Magnete*, published in 1772, in which he exposes his mathematical theory of what he calls the *punctum culminans.*

During the long space of ten years, the magnetic variation was actually observed every *hour of the day* by M. Van Swinden or his pupils. With equal care, during thirteen years, he kept an exact register of the barometer, thermometer, and hygrometer. No circumstance relating to atmospheric phenomena escaped his attention; no aurora borealis appeared during his residence in Franeker but what was accurately observed. Parts of his house and garden were arranged as an observatory. His friends, his pupils, even his servants, sustained the parts of observers during such absences as he was compelled to make. Even in other parts of the country he procured observers, to whom he gave directions and encouragement. By these means, he collected an immense number of facts relating to the subjects of his investigation, whilst by unremitting study, and an excellent memory, he acquired a degree of learning which may almost be said to be unrivalled.

His *Recherches sur les aiguilles aimantées*, to which the Academy of Sciences of Paris adjudged the prize, (1777,) contain such a vast number of observations, and such a variety of curious facts relating to magnetical phenomena, as are seldom found in any writer on natural philosophy. When the Academy of Bavaria (1776) proposed as a prize question the investigation of the analogy between magnetism and electricity, Van Swinden received the *program* so late as to leave him only a few days to prepare an answer to the question. But he had thoroughly considered the subject. The experiments required had been made long before; and the first medal was awarded to him. This paper, together with some others on the same subject, he translated afterwards from Latin into French; and they are well known to philosophers under the title of *Memoirs sur l'Analogie de l'Electricité et du Magnétisme*, 1784.

The *Journal de Physique*, the *Journal des Savans*, the Memoirs of the Academies of Berlin, Paris, of the Royal Society, of the Academies of Turin, Brussels, Haarlem, Petersburg, contain many of his papers. When Charles Bonnet's *Contemplations de la Nature* were translated into Dutch, M. Van Swinden made many additions and notes, which Bonnet judged so important as to have them inserted in subsequent French editions of his work.

Among all these various occupations which took up Van Swinden's time at Franeker, he applied himself with assiduity to various branches of mathematics, as political arithmetic, the doctrine of chances, mortality, tontines, &c. In the works of the Haarlem Society, he gave a new demonstration of Newton's formula of the binomial theorem.

In 1785, he accepted the situation of professor of philosophy at Amsterdam. Amongst the new duties imposed upon him were mathematical lectures. He explained the elements of geometry, and indeed of mathematics in general, in an excellent work, which would have established his fame as a geometer, if it had been written in a language more generally known. In this book, the strictness of demonstration of the ancients is united with practical illustrations, the use of mathematical instruments, and the history of the science. In the last edition of his work, published in 1816, it is striking to find how the venerable author, then far advanced in years, knew and had studied even the most recent publications.

Another work, which he began to publish after he was removed to Amsterdam, is more generally known. The *Positiones Physicae*, as far as they are published, are allowed to rank amongst the best elements of natural philosophy.

Some time after he came to Amsterdam, he was elected one of the directors of the school for the education of seamen. With equal ardour he managed the concerns of the school for the blind; and the interests of the Walloon Church, to which he belonged, found in him a ready and zealous promoter.

As early as 1787, the present minister of marine of the Netherlands had instituted a commission for correcting charts, introducing improvements in navigation, and publishing useful books on nautical subjects. Van Swinden was its chairman. In that capacity he caused the first accurate nautical almanack published in Holland to be printed. He wrote an excellent and extensive work on the theory and practice of finding the longitude by lunar observations, and another on the use of nautical instruments.

In 1798, Van Swinden was one of the two deputies sent from Holland to the Scientific Congress at Paris respecting the new system of weights and measures.

After his return from that capital, he published an elaborate and learned work on the subject of weights and measures, and he greatly contributed to make the new system adopted in the Netherlands.

It was about that period that he was called from his studies to the most eminent functions. Van Swinden himself was soon convinced that politics were not for him, nor he for politics. In that period he had the satisfaction of making government resolve to order a general accurate trigonometrical and astronomical survey of the country; which has since been ably executed by General Krayenhoff. In less than a year, one of those political discussions then so frequent on the continent, drove our author from office, and he cheerfully returned to his studies and resumed his wonted occupations. But when Napoleon gave the management of our affairs to his brother Louis, the new king treated Van Swinden with particular favour, and pressed him eagerly to enter again into political life. This, however, he constantly and firmly declined. At Louis's desire, he framed the plan of the present Royal Institute of the Netherlands. He was at first president, and took a most active part in all its proceedings.

When Holland became a part of Napoleon's immense empire, Van Swinden retired as much from the public eye as was practicable. The king of the Netherlands honoured him with his confidence on many occasions, and, as a Councillor of State, he faithfully discharged his duty. Respected and beloved by his countrymen, full of activity and life, he was suddenly seized with an illness, which he soon felt to be fatal. With that strength of mind which sustained him through life, he foretold and awaited its close; and in his last moments he displayed the calmness, serenity, and resignation, which become a man and a Christian. He expired on the 9th March 1823.

The following is a list of the principal works of this philosopher:—*Dissertatio de Attractione*, 1766. —*Cogitationes de Variis Philosophiae Capitibus*, 1767.—*De Philosophia Newtoniana*, 1779.—*De Hypothesibus Physicis, quomoda sint e mente Newtoni intelligendae*, 1785.—*Tentamen Theoriae Mathematicae de Phaenomenis Magneticis.* Lugd. Bat. 1772, 4to.—*Observations sur le froid rigoureux de Janviero*, 1776. Amst. 1777, 8vo.—*Recherches sur les aiguilles aimantées et leur variations. Memoires Presentés à l'Academie des Sciences de Paris, t.* 8.—*Dissertation sur la Comparaison des Thermometres*, 1778, 8vo.—*Observations Meteorologiques faites à Franeker pendant l'année* 1779. Amst. 1780, 8vo.—*Description of the Orrery made by Eise Eisinga in Friesland.* Franeker, 1780, 8vo. (Dutch.) A new edition of this work is in the press.—*Recueil de Memoires sur l'Anologie de l'electricité et du Magnetismé.* La Haye, 3 vols. 8vo. 1784.—*Description du Planetaire de M. Adams*, 1786. Plano.—*Positiones Physicae*, vol. i. and vol. ii. part 1. Harderovic, 1786, 8vo.—*A Treatise on Finding the Longitude by Lunar Observations.* (In Dutch.)—*A Treatise on the Use of Hadley's Octant and Sextant*, 1788, 8vo. (In Dutch.)—*Explanation of the Nautical Almanack*, 1788, 8vo. Dutch.—*Elements of Geometry*, 1790, 8vo. The last edition appeared in 1816.—*Report on the Census of Amsterdam*, folio, 1795.—*On Weights and Measures.* Amsterd. 1802, 2 vols. 8vo.—*Lectures on Van Laun's Planetarium, Tellurium, and Lunarium.* Amsterd. 1803, 8vo.

Besides these works, many papers by Van Swinden are printed in the Transactions of learned Societies. In those of the Royal Institute of the Netherlands, there is one in the first volume, on the laws of atmospherical pressure. In the third volume of the same collection, there is a paper in which our author maintains the rights of Huygens, as inventor of the pendulum: of this a translation has been given in Dr. Brewster's Journal. See Professor Moll's *Life of Van Swinden* in the *Edinburgh Journal of Science*, vol. i. p. 197.

SWITZERLAND.

SWITZERLAND, the ancient Helvetia, an inland country towards the south of Europe, is bounded on the west by France; on the north by Germany, or, to speak more correctly, by the grand duchy of Baden and the kingdom of Wirtemberg; on the east by the Austrian province of Tyrol; and on the south by Italy or the Sardinian and Austrian Italian territories. It is situated between 45° 50′ north latitude, and between 6° 5′ and 10° 35′ west longitude. Its length from east to west, from Mount Jura to the Tyrol, is 205 miles; from the Lake of Como on the south, to the Rhine on the north, its breadth is 125 miles. Its form is nearly oval. Its superficial extent, which is nearly equal to two-thirds of Scotland, amounts to 18,000 square miles.

The country is divided into cantons, of which the number has been various at different times, but which at present amount to twenty-two. The following is a list, with their respective capitals and population.

Cantons.	Capitals.	Pop. in 1826.
Geneva.	Geneva, .	52,500
Pays de Vaud.	Lausanne, .	170,000
Neufchatel.	Neufchatel, .	51,500
Basil or Bale.	Basil or Bale, .	54,000
Argovia or Argau.	Arau, . .	150,000
Zurich.	Zurich, .	218,000
Schaffhausen.	Schaffhausen, .	30,000
Thurgovia or Thurgau.	Fraunfeld, . .	81,000
St. Gall.	St. Gall, . .	144,000
Appenzell.	Appenzell, . .	52,500

Cantons.	Capitals.	Pop. in 1826
Fribourg.	Fribourg,	84,000
Berne.	Berne,	350,000
Soleure.	Soleure,	53,000
Lucerne.	Lucerne,	116,000
Underwalden.	Stantz,	24,000
Uri.	Altorf,	13,000
Zug.	Zug,	14,530
Schwitz.	Schwitz,	32,000
Glaris.	Glaris,	28,000
Vallais.	Sion,	70,000
Grisons.	Coire,	88,000
Ticino.	Lugano,	102,000
	Total Population,	1,978,000

Switzerland, however, originally comprehended only fifteen cantons; of which eight were formed in the 14th century; the remaining five in the 18th. The names of these are Schwitz,* Uri, Underwalden, Berne, Zurich, Lucerne, Glaris, Zug, Appenzell, Schaffhausen, Fribourg, Soleure, and Bale. This union gave rise to the Helvetic republic, so well known in history. Those territories, now joined to it under the name of cantons, were originally subject or allied to it. The French, in 1798, having taken possession of the country, and wishing to increase the number of their partizans, added six new cantons; viz. the Pays de Vaud, Argau, Ticino, Thurgau, the Grisons, and St. Gall. This number, augmented to nineteen, continued til! the downfall of Bonaparte, when, in 1815, by the Congress of Vienna, three new cantons were added, viz. Geneva, the Vallais, and Neufchatel, making altogether 22, their present number.

There is no country in Europe whose physical appearance is more magnificent, sublime, and diversified, than that of Switzerland. Mountain ridges covered with eternal snow, beautiful and romantic lakes, and verdant vallies, traversed by romantic rivers, silent forests and roaring cataracts, blended with all the varied pictures of gigantic nature, are the characteristics of this interesting country, and render minute description almost impossible.

It is particularly distinguished by its mountains. Even those cantons that are regarded as the most level, viz. Thurgau, Basil, Berne, Zurich, Schaffhausen, Soleure, and Fribourg, present mountains that rise between 2000 and 3000 feet above the level of the sea. The Alps form the most striking and elevated range, not only in Switzerland, but in Europe. This celebrated range, which traverses Switzerland in almost every direction, especially in the south and east districts, extends nearly 600 miles in the form of a crescent, with various inequalities, from the river Var, which separates France from Italy, to the Hadriatic, presenting generally an abrupt face towards Italy, and sloping more gradually on the opposite side. Their principal peaks are Mont Blanc, the loftiest mountain in Europe, 15,646 feet; Mount Rosa, supposed to be only 100 feet lower; Cervin, 13,800; Jungfrauhorn, 13,730; Schrekhorn, 13,812; St. Bernard; St. Gothard; Simplon, over which is the great military road formed by Bonaparte. Though Mont Blanc is the highest, St. Gothard may be regarded as the nucleus, for, though not remarkable in height, it merits this distinction, that the rivers which rise in it and the surrounding group, flow towards every point of the compass. The summit of all these mountains is covered with eternal snow, the snow line in Switzerland at the 46th degree of latitude having been discovered to vary between seven and eight thousand feet above the level of the sea. The sides of many of these stupendous eminences are clothed with glaciers, large masses of ice, formed by the consolidation and partial melting of the snow. These glaciers occupy the plains or hollows of the mountains; their formation takes place about the snow line, or line of perpetual congelation; though, in a winter of unusual severity, they extend considerably lower. "The glaciers," says Mr. Coxe, (*Travels in Switzerland*, i. 41-2.) may be divided into two sorts; the first occupying the deep valleys, situated in the bosom of the Alps; the second clothing the sides and summits of the mountains. As to the first, when the plane on which they rest is horizontal, or only gently inclined, the chasms are but few and narrow; the traveller crosses on foot without much difficulty." Their lower extremities, where they approach the valleys, are in a constant state of solution, giving rise to brooks and rivers, and are maintained, without any apparent diminution of size, by the gradual descent of the masses at the rate of several inches daily in summer. The channels of all the rivers, therefore, that have this origin, are fullest in summer, when ice and snow are melting in great abundance. In their external character, the glaciers present the most varied and fantastic forms, sometimes exhibiting the appearance of a city of crystal, with glistering spires, columns and turrets. Their number is immense, it having been reckoned that there are no fewer than 400 of them in the range along the south of Switzerland. Some of them are known to extend from twenty to thirty miles in length, by one or two in breadth: their depth cannot be so easily ascertained, but is supposed to vary from 100 to 600 feet;† while their total superficial extent has been calculated at 1200 square miles, their formation, it may be added, requires the action of cold to such intensity, that they are peculiar to the Alps, with the exception of a small but elevated tract of the Pyrenees, and a few spots of the mountains of Norway and Lapland. None are found in any other part of Europe.

The action of the sun on these glaciers in summer, so dissolve them, that not unfrequently huge masses, called avalanches, are disunited, and roll

* From this country, distinguished in the struggle for independence in the beginning of the 14th century, the whole country obtained its present name.

† "This depth," which is that calculated by M. Ebel, and has gained the support of M. de Saussure, "must," says M. Simond, "in some places, exceed very much six hundred feet. The minister of Grindelwald assured Professor Wyss, that, having thrown stones into some of the fissures of the ice, he counted twelve or fourteen seconds before they reached the water at the bottom, indicating a depth of 3000 feet, to match the horizontal dimension of 200 square miles, the superficial extent."—(*Travels in Switzerland*, vol. i. 211; see also Coxe's *Travels*, i. 38, for some curious conjectures on the formation and state of the glaciers).

down the declivities to the valleys below, with awful and destructive rapidity, destroying the plains, and overwhelming habitations, villages and forests. These avalanches have sometimes been known to roll down inclined planes of more than twenty miles in length. Avalanches, in the shape of loose dust, or snow frozen but not congealed into one continuous mass, are the most dangerous, on account of the great space they involve, and the whirlwinds accompanying them, which are often so very violent as to tear up trees by the roots, and demolish houses; while an avalanche of compact snow or ice, only strikes a narrow field; the latter sort takes place in spring and summer only; the former in winter.*

From the melting of the snow which covers the mountains, and from the descent of the avalanches, no country in Europe is better provided with rivers than Switzerland. And, from the same circumstance, as previously mentioned, these rivers in summer swell a third or a fourth above the usual size in winter. If we estimate their relative length of course, the Rhone is the most considerable river in Switzerland; and is, besides, the greatest river in Europe, after the Danube and the Volga. It rises on the north-east side of Mount St. Gothard, and, after receiving the waters of a surprising number of streams, it passes through the lake of Constance. It flows thence in a western direction to Basil, before arriving at which place it is augmented by the waters of the Aar, the Reuss, the Limmat, the Thur, the Glatt, the Birs, on the side of Switzerland, not to speak of those on that of Germany. From Basil its course is nearly northward, and it at length loses itself in the German ocean, after a course of 700 miles. The Rhone is next in importance. It rises within five miles of the Rhine, and after flowing through the canton of Vallais, it passes through the lake of Geneva, and, after a course of 500 miles, falls into the Gulf of Lyons. These two majestic rivers either take their rise from glaciers, or are essentially fed by them. In addition to the streams that are tributary to the Rhine, and some of which are large and important, we may mention the Ticino, which takes its rise in St. Gothard, but, unlike the Rhine and Rhone, flows southward, and, after receiving the waters of several streams, and passing through the lake Maggiore, falls into the Po; the Inn which, after flowing through the Grisons, the Tyrol, and separating Austria and Bavaria, joins the Danube; the Adda, which, passing through the Grisons, and directing its course into Italy, loses its waters in the Po.

As connected with the rivers, the lakes require next to be mentioned. Many of them, not confined to the plains, or the mountains, are situated on high table-land, or among mountains of considerable altitude. The following enumeration will show their relative height. The lake of Como stands 692 feet above the level of the sea; the lake of Constance, 1151; Geneva, 1225; Zurich, 1364; Zug, 1406; Neufchatel, 1428; Lucerne, or lake of Four Cantons, 1438; while that of Thun is elevated no less than 1897 feet, being fully a third higher than those of Geneva and Constance, and two-thirds above that of Como. There are many other lakes, such as those of Lugano, Wallenstadt, Brientz, Sarnen, Sempach, Joux, Morat, Bienne. The three last, like Neufchatel, discharge their superfluous waters into the Aar by the Thiele. All these lakes form a superficial extent of 314 square miles. They contain fish, such as pike, trout, salmon, lota, and umber, the last being a very delicate fish, occasionally exported to Paris, and sometimes sold for so high a price as 12*l*.

The climate of Switzerland, as may be inferred from our previous statements, is extremely varied. The extreme cold of the mountains we have already mentioned. Many ravines and portions of valleys are inaccessible, even in summer, to the direct action of the sun; and the immense masses of ice or snow which fall from the mountains on the plains, and remain on them, occasion great variation in the temperature, even in places that otherwise would be genial. The lakes have somewhat of a similar effect. In winter, too, the cold in the valleys is more severe than in most parts of France or Germany; a circumstance which undoubtedly results from the vast accumulation of snow and ice on the mountains. But this is the most unfavourable view of the subject. The valleys and the bases of the mountains exposed to the south, enjoy all the warmth of an Italian sun, and display all the heat and luxuriance of vegetation that characterize more southern climates. Such places produce grapes and the finer fruits in great abundance, and are often resorted to on account of their peculiar sweetness and salubrity. But in this country heat and cold, vegetation and sterility, border on each other, and form the most striking contrast. While, in the plain, the peasantry are engaged in the labour of harvest, the grain is slowly advancing towards maturity, or probably may not be in the ear, on the higher grounds. Nay, so much is this the case, that it has not been inaptly said, snow may be lifted in one hand, while flowers are plucked with the other. Various, however, as the climate is, the mean temperature may be known, when it is stated that at Berne it is about 40° of Fahrenheit, at Zurich about 39°, and at Geneva 40°.

The laborious character of the Swiss has done much for the agriculture of the country. Lofty and most unpromising spots have been cultivated, though they are so inaccessible that manure has to be carried to them, not in the usual way by means of mules or horses, but on the shoulders of the cultivators. Vines and rich pasturages are to be found in places of very narrow dimensions, surrounded by naked rocks or sterile precipices. Cultivation is carried almost to the very verge of the ice and snow lines. The country produces wheat, rye, barley, oats, maize, flax, hemp, tobacco. The stock of corn produced, owing chiefly to the variable nature of the climate, is not sufficient to supply the inhabitants; and by consequence, a considerable quantity requires to be imported. In some rugged districts indeed, the produce is so scanty that the inhabitants are almost strangers to the use of bread, but subsist chiefly on the produce of their dairies. "In Switzerland, as in France," says an intelligent

* See *Travels in Switzerland*, vol. i. 211; see also Coxe's *Travels*, i. 38.

traveller, "arable land lies fallow every third, fourth, or fifth year. The courses are, first, ploughing for wheat, three or four times in one year, without a crop: second, a crop of wheat the next year, which returns generally five and a half for one: third, barley: four, esparsel, (sainfoin) or some other artificial grass; then ploughing again for wheat without a crop. The turnip and sheep system is said not to answer here."—(Simond's *Travels*, i. 35.)

The rearing of cattle forms one of the greatest sources of national subsistence in Switzerland. In spring the herds are driven to the mountains, for good pasturage is obtained as high as the snow and ice lines; and after remaining there till the beginning of winter, they are gradually brought back into the plains, and more sheltered districts. A cow, according to M. Simond, yields in the summer, on an average, six measures of milk daily, each weighing three pounds of seventeen ounces. Cheese, butter, tallow, hides, form some of the chief articles of export from Switzerland.

Of fruits, vines, chesnuts, prunes, peaches, walnuts, cherries, are the most common. In colder situations apples and pears grow; while in the southern valleys the almond and fig are to be found. "The general appearance of the country," says M. Simond, "is very woody, owing to the great number of walnut trees, which grow to an immense size. Every village, farm-house, and gentleman's residence, is surrounded with them. You travel under their shade; and woods, or rather groves, of ancient or very picturesque forest trees are not uncommon."—(*Travels*, i. 35-6.) The vine, it may here be mentioned, grows in the valleys, or on the banks of the rivers or lakes, and terminates at the height of 1700 feet above the level of the sea. The oak succeeds it, and rises to the height of 2800; the beech comes next in order, and flourishes 1200 feet higher than the oak. The firs are found 5500 feet above the level of the sea.

The mineral productions of this country it is not difficult to describe. The Alps are composed chiefly of granite, of a grayish ash or bluish colour, and in some places mixed with marble. Calcareous strata, alternate with layers of fine sand, are common. These mountains also disclose porphyry, marble, and alabaster. Iron, lead, zinc, cobalt, bismuth, arsenic, and antimony, are found in various places, both in veins and in masses, but are not much cultivated. Rock-crystal is very common, and forms an article of export. Sulphur is found in many places; as also coal; and several rivers, the Rhine, the Aar, the Adda, and the Reuss, carry down gold. Strata of lignites or bituminous wood are wrought in several valleys, and the inhabitants use it for fuel. Mineral springs, of which the principal are those of St. Maurice, in the Grisons; Gurnigel, in Berne; Pfeffers, in Thurgau, abound in Switzerland more than in any other European country.

We have spoken of the fish, and the large cattle with which Switzerland abounds. Horses, mules, and oxen are used for the purposes of husbandry. Goats, sheep, and hogs are reared in great abundance. The weasel, pole-cat, ferret, badger, and squirrel are common. Of game, the white hare, the same sort as that in Siberia, the chamois, and the marmot, which last is considered a great delicacy, are the most important. The other animals are the fox, the hamster, a species of rat prized for its skin, different kinds of martens, the wild boar and the bear, the last being found chiefly in the mountains of the Vallais. Crows, eagles, vultures, are also common.

The manufactures of Switzerland cannot be expected to be either very numerous or very extensive. Yet they are not inconsiderable. The cotton manufactures of St. Gall have been noticed by every traveller, and are the most extensive in the whole country. If the circumstance stated by M. Ebel be correct, that in the canton of St. Gall alone, from thirty to forty thousand women were employed in embroidering muslin, the whole manufacturing population in that canton must be extremely great. There are also cotton works in the cantons of Zurich, Berne, and Appenzell. Linens of every kind of fabric, as also silks and woollens, are manufactured in Switzerland. Clocks and watches have long formed a staple produce of their industry and skill.

Switzerland possesses considerable facilities for commerce, though she has not very eminently gained the character of a commercial nation. Not only are the Rhine and the Rhone, but some of their Swiss tributaries, navigable, thus connecting the country with Germany, the Netherlands, and the German ocean, on the one hand; and on the other, with France and the Mediterranean. Cattle, hides, and the produce of the dairy, are the chief exports from the pastoral districts; while the exports arising from manufactures are watches and clocks, linen, cotton, and woollen cloths, and in a small degree silks. Pharmaceutical plants form a considerable branch of exportation.

The national character of the Swiss has deservedly been the subject of praise on the part of writers of every kind. Though the country consists of a variety of states, some of them formerly independent, and each varying in institutions and manners somewhat from the rest, yet the character of the people is almost unvaried, being amiable and simple. They are eminently remarkable for their love of country, a feeling certainly common to them with others, but which they seem to possess to a degree altogether unrivalled. This may arise in no small measure from the romantic features of their native land; for it seems to be an invariable principle, that patriotism is strong in proportion as the country to which it refers is distinguished by such features.* "This unconquerable passion," says Mr. Pinkerton, "seems to arise in part from

* "And even those hills that round his mansion rise
Enhance the bliss his scanty fund supplies;
Dear is the shed to which his soul conforms,
And dear that hill which lifts him to the storms.
* * * * * *
Even the loud torrent, and the whirlwind's roar,
But bind him to his native mountains more."
Goldsmith.

a moral sensibility to the enchanting ease and frankness of the native manners; and in part, from the picturesque features of the country, the verdant hills contrasted with Alpine snows, and delicious vales watered by transparent streams, scenes nowhere else to be discerned in such perfection, and which must powerfully affect the imagination,—the parent of the passions." The Swiss, indeed, possess this passion in so remarkable a degree, that, though no people emigrate more, there are few who do not return to their native land to lay down their bones beside those of their fathers. This love of country is liable to be excited and called into action by circumstances apparently trifling. Hence, in the French armies, composed of Swiss mercenaries, the tune called the Rance des Vaches, which in their youth they had heard so often sung by the Swiss milkmaids when they went to the pastures, was carefully interdicted, because it melted the rough Swiss soldier into tears, and not unfrequently led to desertion. The Swiss have long been as much distinguished for bravery as for patriotism. This virtue has been often eminently and successfully displayed in maintaining the independence of their country; and as mercenaries, they are regarded as forming the best soldiers in Europe. Like other people in a comparatively rude state of society, they are fond of traditions and of ancestry, and feel great reverence for ancient customs and institutions. Their love of freedom is extraordinary; and they are always ready to risk or sacrifice their life in defence of it. "The human mind, however," says a modern writer on Switzerland, "is made up of so many contradictions, that in this country, where liberty has been established for several ages, some remains of the worst of governments are suffered to remain; justice is privately administered, and the torture is still in use." They are fond of labour, by which they have surmounted every disadvantage of soil and climate, and have spread fertility and beauty over spots which nature seems to have meant for everlasting barrenness. They are farther characterized by great simplicity of manners, by an open and unaffected frankness, by hospitality, honesty, and all the virtues of private life. Crime is rare; and instances of capital punishment seldom occur. The Swiss in general are not given inordinately to dress; yet in some cantons sumptuary laws have been framed to prevent idle ornament. Different costumes, the origin of some of which is very ancient, prevail in different districts. The dress of the women, however, generally consists of a short ample petticoat of dark brown; red sash; blue stockings seen as high as the knee; large flat hat without a crown, tied under the chin. Games of chance are prohibited; but gymnastic exercises form the daily amusements of the young; they engage in the race, in wrestling, in throwing the dart, or shooting at the target. Although the Swiss cannot be regarded as a very poetical people, they are devotedly fond of music; and of all the arts, it is most carefully cultivated. The observations which we have made under this head are chiefly applicable to the rural and pastoral class of the people. The manners that obtain in the large towns are considerably different, and are rapidly becoming similar to that state of society, which, under similar circumstances, prevails in general Europe. The men are tall, robust, and well made; the women are handsome, modest, frank, and agreeable in conversation.

We cannot conclude this portion of our subject without referring to the *goitres*, wens, or excrescences on the neck, to which in certain districts the Swiss are so liable. These excrescences are of incredible size, varying, as Mr. Coxe assures us, from the size of a walnut to almost the bigness of a peck loaf. They are not hereditary, as has been alleged, because many persons whose parents were free of them, have either been born or have become goitrous. Of the causes of goitres there have been various conjectures. The notion that snow-water occasions them is totally devoid of foundation; for on that supposition they would be most common in the interior and southern portions of the kingdom; which is not the case. They are as common in the north as elsewhere; and, besides, goitres are found to obtain, not merely in the champaign districts in the north of Italy, and in the neighbourhood of Naples, but in several parts of the East Indies, where snow is unknown. Nor is the opinion, that they owe their origin to the concentrated heat of the climate, and to the stagnation of the air, better founded. The truth is, it seems now to be universally believed, that the excrescences in question are to be attributed to the carbonate of lime, or *tuf*, as it is called in Switzerland, with which the springs are impregnated. The following illustration of this opinion, in the correctness of which subsequent writers most fully agree, we owe to an intelligent traveller, to whose work we have so often referred. "A surgeon, whom I met at the baths of Leuk," says Mr. Coxe, "informed me that he had not unfrequently extracted concretions of *tuf-stone* from several goitres; and that from one in particular, which suppurated, he had taken several flat pieces, each about half an inch long. He added, that the same substance is found in the stomach of cows, and in the goitrous humour to which even the dogs of the country are subject. The same gentleman assured me that in the course of his extensive practice, he had diminished and cured the goitres of many young persons by emollient liquors and external applications; that his principal method, in order to prevent them in future, consisted in removing the patients from the places where the springs are impregnated with *tuf* or calcareous matter; and, if that could not be contrived, by forbidding the use of water which was not purified. He confirmed the report that infants are occasionally born with guttural swellings; particularly those whose parents are goitrous; and remarked that one of his own children had at its birth a goitre as large as an egg, although neither he nor his wife, who were both foreigners,* were afflicted with that malady. He had dissipated it by external reme-

* "In the former instance, goitres may, though perhaps erroneously, be termed hereditary; but in the latter, where the parents are both foreigners, and not goitrous, can scarcely be derived from any other cause than the aliment of the mother.

dies,* and, since that period, had invariably prohibited his family from taking the spring waters, unless they were distilled, or mixed with wine or vinegar, by which means he was able to preserve them from those humours in the throat that were extremely common among the natives of the town which he inhabited."—(*Travels*, i. 401-2). Goitres, we may conclude by mentioning, are most common in the cantons of Berne, Lucerne, Friburg, and Vallais, but particularly in the last; and in all of them the carbonate of lime is found in solution in almost all the springs.

Goitres have been described as checking respiration, and rendering those afflicted with them indolent and languid. But this, it is feared, is not their only effects. They are regarded as producing idiocy, or, it is supposed that the same causes that produce the one, occasion the other, thus affecting both the mind and the body. This fact is certain, not only that idiocy prevails most where goitres abound, but that idiots are most frequently both goitrous themselves, and are descended of parents so afflicted. The truth, in fine, is that idiocy, whatever is the cause, and the one assigned is the most likely, obtains more in Switzerland, particularly in the Vallais, than in any other known country or district in the world.

Switzerland is remarkable for nothing more than for the means of education it possesses, and the consequent intelligence of its inhabitants. In this respect it is not inferior to the best educated countries in Europe. When the means of education are sufficiently ample in a country, from one-ninth to one-tenth of the population are attending school. In Scotland, where our parochial schools afford us such facilities, the proportion undergoing education is below that average. In England, the deficiency is still more apparent. In France not more than the 28th part of the people are enjoying the blessings of education; while in the Pays de Vaud the proportion is one-eighth, being more than the average; so that the inhabitants of this district have been pronounced the best educated in Europe. The state of schools, however, is different in the different cantons. In none of them, however, is this important subject neglected; but education is more generally diffused among the catholic than the protestant states. The most improved plans of instruction, such as that of Bell and Lancaster, have been introduced; and every means have been used to promote the great object in view,—the education of the people. Nor has Switzerland merely introduced the plans of others; she has, with great success, tried methods of her own, and has thus lent her aid to the great cause of education. The celebrated school of Pestalozzi, at Yverdun, in the Pays de Vaud, has been visited and celebrated by every traveller. This was the first seminary in which the intellectual system, as it has not inaptly been called, or that system which consists, not in mechanical routine, as is still too common in schools, but in illustrating the rationale of every subject taught, and of cultivating the mental faculties, had its origin, and was brought to great perfection. It embraces also the plan of mutual instruction on the part of the pupils, as recommended by Bell and Lancaster. Of the old and new systems, as ascertained in this canton, the comparative result is most clearly favourable.

By the Old System.	*By the New System.*

Nor is the establishment termed the School of Industry, of Mr. Fellenberg, at Hofwyl, in the canton of Berne, less celebrated than that of Pestalozzi. The object of this seminary is to combine scholastic education with industry; which at Hofwyl is agricultural, but which might, in towns for example, be manufacturing, or of any kind whatever. We have not time to examine into the real merits of this scheme, for an account of which we refer to Simond's *Travels*, (vol. i. 407-20,) and to an excellent article in No. 64 of the *Edinburgh Review;* but we may mention that, like that of Pestalozzi, it has given a great impulse to education throughout the country, and has produced some very eminent scholars. Pupils of the highest rank come to it from Germany, France, England, &c.—Of the other seminaries in Switzerland the character stands high. In most of the cantons education is a matter of state, and is under the immediate protection of government. Not to speak of the schools in the country districts, most of the large towns enjoy similar most efficient institutions; and in Zurich, Berne, and Lausanne, there are academies or colleges of great reputation. The universities of Basil and Geneva have long been celebrated, and can exhibit in the list of their pupils and professors some of the greatest names in Europe. Since the revival of learning, Switzerland can boast Zuinglius, and Oecolampadius, Bullinger, and Beza, the reformers; Hans Holbein, the celebrated painter;† Ischudi, who died in 1592, and who has been characterised by M. Simond, as "the first and greatest historian in Switzerland;" Paracelsus, the physician and alchy-

* We may here mention that Dr. Coindet of Geneva has recommended the use of iodine as a specific for the cure of goitre. The truth is, burnt sponge was long applied with considerable success to remove the excrescence in question before the cause of its efficacy was known; and it is only of late that iodine has been discovered to exist in it. The same substance has been detected in various mineral springs, the waters of which have been found efficacious in that disease. The form in which it is used are the tincture, and the hydriodate of potassa, the dose of each being about ten drops. It is also appliedby friction as an ointment, mixed with lard, in the proportion of one drachm of iodine to three of the latter substance.

† Though a native of Basle, Holbein may be regarded as more an English than a Swiss artist. Neglected by his native country, he came to England in the 30th year of his age, under the patronage of Henry VIII. where he continued the remainder of his days. He died in London of the plague in 1554, aged 58. He may be said to have been the founder of the art, in which he excelled, in Britain.

mist; Turretine; Ostervald; Conrad Gesner, and his descendant John Gesner, both naturalists; Solomon Gesner, styled the Theocrates of Germany; also Bodmer, "justly denominated," says Mr Coxe, "the father of German literature;" Hottinger, the historian; Senebier, the literary historian; Bonnet, the naturalist and metaphysician; Mallet, the historian and antiquary; Leonard Meister, the historian; Albert Haller; the two Bernoullis, mathematicians; Saussure and de Luc; Zimmerman; Rousseau; Lavater; Euler; Necker. Physical philosophy and natural history, profane history and antiquities, biography and bibliography, are the branches in science and literature most cultivated in this country.

The public libraries of Switzerland are such as become the literary character of the country. Those of Berne, Geneva, Basil, Zurich, Lucerne, are the most extensive and the most valuable. Their collections vary from 30,000 to 60,000 volumes, of which many are rare, some are unique. They contain many important manuscripts, literary, historical, and classical;* many medals and curiosities; and some of the best editions of the classics, particularly the early impressions of the 15th century. These manuscripts embrace a great number of the letters of Zuinglius and the early reformers. There are many other libraries belonging to colleges and public bodies, some of them of great extent and importance. Libraries belonging to private individuals are very common, and not inferior to those of any other country, one individual being mentioned by Mr. Coxe as possessing a collection of no fewer than 15,000 volumes, all valuable, many of them rare, no fewer than 700 having been printed in the 15th century. Botanical gardens, museums, and scientific collections are numerous. There are many literary, philosophical, and scientific associations in Swizerland, as well as others, whose object it is to promote agriculture and internal improvement. Berne, Geneva, Lausanne, Zurich, Basle, Lucerne, and many other places can boast of such societies. "The Swiss," says M. Simond, "have just revived a custom dropped during the last anxious period of a revolution, that of an annual meeting of their learned men, principally naturalists, in each of the cantons successively. The object, moral and political, as well as scientific, is to bring together, during three days, distinguished men of the different parts of the union, who otherwise would have remained personally unknown to each other."—(*Travels*, i. 319.) Communications are received, and memoirs and papers are read, and discussions of every kind take place, as in other scientific associations. Such meetings, while they show that physical investigations are of national importance, are calculated to promote emulation, if not in one sense, to reward it.

In Switzerland there are 130 printing presses scattered throughout the cantons, of which Geneva has the greatest proportion. These presses, however, are not always fully employed. There are several scientific and philosophical journals published. The number of newspapers amounted in 1826 to 28, of which 22 were written in German, four in French, and two in Italian. A considerable proportion of these papers appeared twice weekly; but only one, (*The New Gazette*, a Zurich publication,) thrice a week. In some cantons a rigorous censorship exists over the periodical press.

It is evident from the foregoing head, that the three languages there mentioned must be spoken and understood in Switzerland. But the German is more commonly used than any other; and the greater number of the eminent authors of the country have written in that language. In the southern districts Italian is in use. French obtains in the west, namely, in the cantons of Geneva, Pays de Vaud, Neufchatel, and in part of those of Berne, Fribourg, Soleure, and Vallais. German is spoken throughout the remainder of the cantons. But in several of these cantons, the lower orders make use of another language, consisting of several dialects, slightly different from each other. It is regarded as the ancient language of the country, and is held in high estimation by thōse among whom it prevails. It is a branch of the Celtic, with the admixture of several words of Greek and Latin derivation.

The reformed doctrines, as we have already hinted, were early introduced into Switzerland, and some of the earliest and most eminent reformers were natives of that country. It was from Geneva, where Calvin and Beza taught, that Knox, the Scottish reformer, introduced the presbyterian polity into this country. The different cantons, however, are very different in regard to religious character and dicipline, the catholic faith being yet retained by about one-third of the whole population. The cantons of Soleure, Fribourg, Lucerne, Zug, Schwitz, Underwalden, Uri, Ticino, and Vallais, still continue popish. Those of Argau, Glaris, Thurgau, St. Gall, Appenzell, and the Grisons, are partly catholic and partly protestant. The other cantons are protestant. Though illiberality and persecution have been, even of late, displayed in this country, toleration seems to be now permanently established. The following table gives a relative view of the different religious sects in 1821. The protestants, we may remark, generally entertain the doctrines of Calvin.

* In the library of Zurich are three Latin letters from Lady Jane Grey to Bullinger. They are written with her own hand; they breathe a spirit of the most unaffected piety; and prove the extraordinary progress which that unfortunate and accomplished princess, though only in the 16th year of her age, had made in various branches of literature. The Greek and Hebrew quotations show that she was well acquainted with these languages. These letters, though given in several publications, are not printed with any regard to accuracy. (Coxe, i. 96.)

Switzerland, though a republic, does not form one great community like Greece or Rome; but, like the United States of America, it is a confederacy, or combination of several petty states, each being distinct and different from the rest. All the Swiss cantons, however, are independent, possessing, by an inherent right, the privilege of managing, respectively, their internal and private affairs; but their several constitutions are so different that they may, in this respect, be classed in the following manner: I. Neufchatel, which, till the year 1815, belonged to Prussia, is the only one in which monarchial forms of government are modified by republican institutions. II. Schaffhausen, Zurich, Basil, Soleure, Berne, Lucerne, and Fribourg, form aristocratical governments; in which several privileged families possess the direction and management of public affairs. III. Thurgau, Argau, St. Gall, Pays de Vaud, Geneva, Vallais, and Ticino, are representative republics. And IV. the people of Appenzell, Zug, Schwitz, Uri, Glaris, and Underwalden, live under a democratic government: the citizens form general assemblies, nominate their magistrates, and deliberate on the interests of the republic. The general interests of the Helvetic republic, such as the conclusion of foreign alliances, the defence of the country, &c. are managed by a general assembly or diet, composed of deputies from each of the cantons, and which holds its meetings successively at Berne, Zurich, and Lucerne. At these diets all matters are decided, by a plurality of votes, excepting declarations of war and treaties of peace, which require three-fourths. The diet assembles at least annually, but oftener when necessary.

The Swiss are quite a military people. Every artizan is a soldier, or must be enrolled in the national militia, at the age of twenty, and be clothed according to the military uniform of his canton. Each canton, in the event of a war, furnishes a contingent; and all the contingents amount to 33,758 men. The Swiss, in military affairs, have for centuries been remarkable for a very peculiar practice, namely, letting out troops for hire to foreign powers, on the condition of their forming separate regiments, and not intermingling with the troops of any other country. This practice was acted upon so recently as during the late war, and in Spain till 1820. Swiss mercenaries have gained a name for valour and skill inferior to that of no other country. To provide for the maintenance of the army, and for other expenses, the cantons impose on themselves a tax in proportion to their relative population and resources. The revenue of the confederation, cannot, on this account, be great; indeed it was so small in 1826 as L.500,000; but the debt was only the fourth of that sum, or L.125,000.

Of the towns of Switzerland we mean not to give any account, as of the most important of them such an account has already been given under the proper articles. None of them are large. Geneva, the largest, contains only 25,000 souls; Berne, the next in size, 17,600; Basil, 16,300; Zurich, 10,400; Lausanne, 10,220; the rest contain fewer, varying from 9,000 down to 1,700, the population of Altorf.

The history of Switzerland, previously to the time of Cæsar, may be regarded as unknown or uncertain. It may, as has been believed by one class of writers, have been visited and colonized by the Greeks, who founded Marseilles several centuries before the time to which we refer. This opinion has been supposed to gain countenance from statements made by Herodotus and Appolonius Rhodius; and an expression made use of by Cæsar seems farther to corroborate it. *In castris Helvetiorum tabulae repertae sunt, litteris Graecis confectae*, (*Comment. de Bell. Gall.* lib. i. cap. xxix.) But whether the opinion be correct or otherwise, cannot now be ascertained. Nor do we stop to inquire. At the dawn of authentic history, we find the country inhabited by the Helvetii and the Rhaetii; the latter inhabiting, in addition to Swabia and the Tyrol, what afterwards formed the Swiss cantons of Appenzell, Glaris, Uri, and the Grisons; the Helvetii occupying the remaining cantons. These people were of Celtic origin; and remains of the Celtic language, which was long their native speech, still exist. Their defeat by Cæsar is well known. They were afterwards ranked among the people subject to Rome, and were exposed to all the hardships which such a connexion always imposed on conquered nations.* On the downfall of the Roman power, the Helvetians, like the other people of Europe, were overrun by hordes of barbarians; they were successively conquered, and nearly extirpated by various tribes, the Alemanni, the Franks, the Huns, the Burgundians. From the beginning of the eleventh

* Aventicum was the capital of the country in the time of the Romans. It is now called Avenches, and is situated in the Pays de Vaud. Its walls can still be traced, inclosing a space about five miles in circumference, part of which are occupied by the present town. It can boast of many magnificent remains.

century, the provinces which now constitute Switzerland, began to be regarded as an appendage of Germany; and are mentioned in history as receiving at different times certain privileges and immunities from the head of that empire. These, however, did not proceed from the spontaneous policy of the emperors: they were wrested from them in consequence of the repeated applications and urgent remonstrances of the Swiss themselves, who seem from the earliest periods to have abhorred dependence, and to have been animated with principles of liberty. In truth, the inhabitants of Uri, Schwitz, and Underwalden, (three territories known by the name of the Waldstetten) possessed from time immemorial the right of being governed by their own magistrates, and of enacting their own laws; they had always declared themselves averse to the authority of the emperor's representative among them; and when, like the rest of the country, they did consent to acknowledge this officer, it was on the condition that he would govern according to law, and make no encroachments on their rights and privileges. Usurpation, however, followed after usurpation, till at length the whole country was reduced under the power of the house of Austria. Tyranny in truth was carried to the utmost extent, and freedom seemed to be for ever extinguished in Helvetia. But it was checked, not destroyed; its spirit still continued to linger among them; and at length it burst forth with a greater energy than ever. A confederacy to shake off the yoke of their oppressors, and to achieve the independence of their country, was formed in 1307 by three individuals, natives respectively of the three cantons that composed the Waldstetten. The conspiracy was embraced with delight by all to whom it was communicated; the names of the heroes who organized it have ever since been revered throughout Switzerland; and the spot where it was first formed is regarded as sacred. The revolution which was contemplated, was accelerated, or rather secured, by the insults shown on the part of Gessler, the representative of the Emperor, to William Tell, one of the early conspirators, and the greatest of Swiss patriots, and by the intrepid spirit he showed in return. Tell was taken prisoner by his oppressor; but while being conveyed on the lake Lucerne to Kussnacht, the residence of the latter, he made his escape, and hastening by land, surprised the tyrant near his castle, and shot him on the spot with an arrow. This brought matters to a crisis. The Waldstetten at once availed themselves of the advantage they had gained; the intestine troubles of Austria prevented that power from taking effective retaliatory measures; the authority of the empire was thrown off; and the independence of the oppressed country established. On the 7th of January 1308, the people of the Waldstetten assembled, and took an oath of perpetual alliance.

Every thing connected with the history of William Tell is interesting. He was born of humble parents, at Burglen, in the neighbourhood of Altorf, the capital of Uri; and was married to a daughter of William Furst, one of the three original conspirators. On the spot on which Tell landed when he escaped from Gessler, a chapel was erected, thirty-one years after his death, to commemorate the event. In the interior of the building, the most celebrated actions of the patriot's life are coarsely painted. He fought at the famous battle of Morgarten, of which we shall immediately speak. Instead of courting places of emolument or distinction, he refused them when offered to him. The highest official dignity he accepted was that of first magistrate of Burglen. His death, which happened in 1368, when he had attained to advanced years, was accidental, and took place in connexion with an event not unworthy of his patriotic life. He was drowned in attempting to rescue a boy who had fallen into a stream which passes by his native place. He left behind him a name the most illustrious in the Swiss annals.

But Austria, though, as previously mentioned, she could not effectually oppose or prevent this revolution, adopted measures for this purpose, so soon as her intestine commotions would permit. In the year 1315, Leopold, Duke of Austria, marched against the independent cantons with an army of 20,000 men. Nor were the patriot band, which, though few, were undismayed, unprepared to receive them. The latter amounting only to 1400, seeing that their invaders were intending to force their way into their liberated territory at Morgarten, a narrow pass formed by the lake Algeri, and a neighbouring mountain, resolved to make a stand at this formidable strait: and, after imploring the divine assistance, they took up an advantageous position on the mountain. The result, which, in some measure, recals to our minds the battle of Thermopylae, was as glorious to the patriots, as it was worthy of their cause. The whole Austrian army was either killed or dispersed; while the loss of the Swiss is not estimated at more than fourteen. This defeat settled the question between the two countries. In the same year the three cantons of the Waldstetten confirmed at Brunnen the alliance recently formed: and the Helvetic confederacy dates its foundation from this period, namely, the year 1315. It consisted at first of the three cantons already mentioned: during the course of the same century, Berne, Zurich, Lucerne, Glaris, and Zug, joined the confederacy; and other five, namely, Appenzell, Schaffhausen, Fribourg, Soleure, and Basil, in the beginning of the 16th, thus forming the thirteen cantons so well known in history.

Meanwhile, indeed so early as the eighth century, christianity was introduced into this country, by two Scotsmen, educated at the famous monastery of Iona, founded by St. Columbus. The reformed doctrines were also early introduced; and the name of Switzerland is intimately connected with the history of the Reformation.

The history of the Swiss confederacy ceases to be interesting for many centuries subsequent to the union of the thirteen states. These states, notwithstanding intestine quarrels about religion, continued to flourish, to cultivate and enjoy the friendship of each other, and to be at peace with the other states of Europe. It is not till the year 1798, that the history of the Helvetic confederacy began again to be connected with that of the surrounding countries. Contrary to the express treaty concluded between France and the country under review in 1792, the French Directory made a hostile descent on the canton of Basil in the year 1797. The Directory, without any other motive than the hope of plunder, excited, says M. Schoell, a revolution in Switzerland, and under pretence of being invited by one of the parties, they sent troops into that country; overturned the existing order of things; and under the title of the Helvetic Republic, established a government entirely subject to their authority.

Such was the downfall of the ancient constitution. The Swiss, enslaved by the Directory, made several bold efforts to regain their former independence, but in vain. Nor were they firmly united, else success might have crowned their exertions. Two parties, which had long existed, though they had not openly avowed themselves, now appeared, and Switzerland experienced a series of revolutions in which the unionists, or aristocratical party, and the federalist or democratic alternately had the ascendency. A civil war now tore this country, so long peaceful and happy. A French army, under the command of Ney, again entered it, and established (1803,) a constitution, not of a kind wished for by the majority of the people, but recommended by Bonaparte, now consul of France. This constitution is known in history by the name of *the Act of Mediation;* and Bonaparte, putting himself at the head of it, commanded the able cooperation of the Swiss in his future wars. Switzerland, as before mentioned, now included nineteen cantons; the constitution of each of which was more or less democratic; while the equality of the citizens formed the basis of them all. Under such circumstances, with the exception of some partial commotions, did this country continue till the success of the allied forces emancipated her from the grasp of her conqueror. Immediately on this event, the cantons were far from being agreed as to the future constitution of the country. A civil war, indeed, was likely to be the consequence. But the Congress of Vienna, which met in 1815, and fixed the boundaries of the different countries of Europe as they now stand, prevented this calamity, by taking the case of Switzerland into their consideration. They did for her more than her best friends could have expected. They restored her independence. They made, as stated in the beginning of this article, an addition of three new cantons to her territory. They granted to her that constitution of which we have already given an account.—Under all these advantages, however, the Swiss cantons cannot be looked upon as greater than a third rate power; but in other respects, particularly with regard to literature, education, and civil privileges, she is not inferior to almost any of the first powers in Europe.

See the Articles AUSTRIA and FRANCE: Muller's *History of Switzerland:* Koch's *Revolutions de l'Europe,* with Schoell's *Continuation; Travels in Switzerland,* by Ebel, Coxe, and Simond: Saussure's *Voyages dans les Alpes; Annual Register* for 1815. (T. M.

SYDENHAM, THOMAS, a celebrated physician, was born at Winford Eagle in Dorsetshire about the year 1624, and was the son of a gentleman of independent fortune. He was sent to Oxford in 1642, and after taking degrees there and also at Cambridge, he practised in Westminster. He died, December 1689, in the 65th year of his age. A very full account of him as a medical writer has already been given in our Article MEDICINE, Vol. XII. p. 730.

SYDNEY, a town of New Holland, and capital of New South Wales. It is situated on the two necks of land which form Sydney cove. The town, which has now considerable regularity, covers a great extent of ground. The public buildings are handsome, and there are many excellent houses, though the greater number are of a mean aspect. The government house is a handsome building. A bank was established here in 1817, and there are two excellent public schools for the education of children of both sexes. The expense of it is defrayed by a tract of land of 15,000 acres, stocked with horses, cattle, and sheep, a part of which, both land and stock, is given in dower to every female that marries with the consent of the committee. There is here an auxiliary Bible Society and a Sunday School institution, which were instituted in 1817. Besides the public schools there are various private seminaries for boarding and educating the children of the wealthier inhabitants. Population about 8000. East Long. 151° 25′. South Lat. 33° 15′.

SYENE, SIENNA, or ASSUAN, a celebrated town in Upper Egypt. The principal antiquities here are a small temple, supposed to be the remains of Eratosthenes's observatory, the remains of a Roman bridge, and the ruins of the Saracen town. The latter include the city wall, built of unburned bricks, and defended by square towers, several mosques with lofty minarets, and many large houses in a state of wonderful preservation. There is a castle at Syene, commanded by an aga, but it is poorly defended. There is also a handsome stone quay. East Long. 32° 54′ 34″. North Lat. 24° 5′ 23″. See ASTRONOMY. Vol. II.

SYLLA, See ROMAN EMPIRE, Vol. XVI. p. 401.

SYMPIESOMETER, from συμπιεζω, *to compress,* and μετρον, *a measure,* is a barometrical instrument invented by Mr. Adie of Edinburgh, for measuring the weight of the atmosphere by the compression of a column of hydrogen gas enclosed with a column of almond oil. A drawing and description of it have been already given in our Article METEOROLOGY, Vol. XIII. p. 166. See the same Article, page 178.

SYRACUSE, an ancient city and republic in Sicily, celebrated for its splendour, its wealth, and its military prowess; but now most illustrious as having been the birth place and residence of Archimedes, whose genius and labours have survived the memory of all its other greatness.

The ancient city of Syracuse was surrounded by a treble and almost impregnable wall 18 miles long, and contained four considerable cities, Acradina, Tyche, Neapolis, and the Island of Ortygia.

Acradina, (See Acradina, Vol. I.) situated on the shore, was separated from Neapolis and Tyche by a wall of extraordinary thickness and altitude. Tyche was built between Acradina and the steep and rugged hill called Epipolæ, and contained the great gymnasium and several beautiful temples, particularly that of Fortune. Ortygia was united to the other cities by a bridge, and contained the palace of Hiero and the magnificent temple of Diana and Minerva. Neapolis, or the New City, formed the western extremity of Syracuse, and was defended by high ground. The principal ornaments were the temples of Ceres and Proserpine, a theatre and amphitheatre, and the statue of Apollo Temnites, afterwards carried to Rome.

Syracuse had also four fine harbours, separated by the island; the greatest, which was 5000 paces in circuit, and about two miles long and one wide, was formed by a point of the island Ortygia on one side, and on the other by the little Island and Cape Plemmyrium. Its entrance was 590 paces wide. It ran into the very heart of the city, and was called *Marmoreo* from its being encompassed with marble edifices. The lesser harbour is on the North East of Ortygia, and near it is still shown the site of Archimedes's house, and the tower from which he burned the Roman galleys.

Modern Syracuse occupies the south-east corner of the ancient city, and contains Ortygia, and part of Acradina. It is surrounded by a wall, and is defended by draw-bridges. Though the streets are narrow, yet they are tolerably regular, and the houses are upon the whole pretty well built. The ancient temple of Minerva has been converted into the cathedral of the city, and is dedicated to the Virgin Mary. The ancient amphitheatre still exists and attests its former grandeur. It is 300 feet long by 200 wide, and the arena, the sides and passages, were all cut out of the solid rock. A part of the long wall built on the north side of the city by Dionysius still remains. It is seven feet high, and 10 feet thick. The catacombs of Acradina still exist. They are about a mile long and eight feet high, containing many tombs and sepulchral caverns. The Ear of Dionysius is a gulf or cave 170 feet long by 60 high, and from 20 to 35 wide, possessing a powerful echo. The fountain of Arethusa still discharges the contents of a river, and that of Cyane, a few miles from the town, sends out a copious stream. In the year 1810, a beautiful statue of Venus, without the head, was dug out of a heap of ruins under a tree, and by a little expense other objects of antiquity might easily be obtained. An hospital, with a number of churches and convents are the only other objects in the city. The exports from the town are wax, wheat, oil, hemp, and slates. Population 14,000. East long. 15° 27-3'. N. lat. 37° 3'. See our articles Archimedes, Vol. II. p. 307. Athens, Vol. III. p. 27. Burning Instruments, Vol. V. p. 51.

SYRACUSE, a fine flourishing post village and seat of justice, Onondago county, New York, situated on the Erie canal at the point where the Salina side canal leaves the main trunk, 25 minutes north of west from Albany; 47 miles W. from Utica, and by post road 342 miles a little E. of N from Washington city.

The village of Syracuse stands at the foot of a range of hills, out of which and flowing to the north issues Onondago creek, which about two miles below enters the lake of the same name at the village of Salina. In a state of nature the space between the hills of Syracuse and the Onondago lake was an alluvial flat, liable to annual inundation, but the side canal which connects the Erie trunk with Lake Ontario by way of the Oswego river, has been extended from Syracuse and into Lake Onondago by a series of locks at Salina.

The side canal assists to drain the flats which are also desiccated by other drains, and by an operation at its outlet, which has lowered the level of Onondago lake. The salines or salt flats are at the village of the same name. When the writer of this article visited these places in 1823, the operations of draining the flats, those on the Onondago canal, and the erection of extensive pans to make salt by solar heat, were all in a state of forwardness.

SYRIA, a province in the Turkish empire, consists of five pachaliks; viz those of Aleppo, Tripoli, Damascus, Acre, and Palestine. It is 150 leagues long and 35 broad, and contains about 5256 square leagues, and the population is reckoned at two and a half millions. See Aleppo, Palestine, Damascus, Palmyra, and Turkey. See also Volney's *Travels in Syria*, and Clarke's *Travels*, vol. ii.

SYROS or Syra, an island in the Grecian archipelago, about 36 miles in circuit, and 14 long. The town of Syra is built on the summit of a lofty hill, so conical that it resembles a vast sugar-loaf covered with houses. The quay, with several warehouses, is at the base of this cone. Near the harbour, which is tolerably good, there are some ruins, and it is said that many ancient marbles are buried behind the magazines. The modern town probably occupies the site of the ancient Acropolis. The streets of Syra are dirty and narrow; and the old fountain still exists near the town, discharging its limpid water from the solid rock. The productions of the island are wines, figs, cattle, barley and wheat. The inhabitants, who are all Greeks, profess the Catholic religion. Population 4000. East Long. 24° 34'. North Lat. 37° 22'. See Clarke's *Travel's*, vol. iii. p. 424-433.

SZEGEDIN, a large town of Hungary, in Csongrad, opposite to the conflux of the Theyss and Maros. The principal public buildings are a theatre, a work-house, several hospitals, a monastery of Minorites, a school of the Piarist monks, a gymnasium, and a small academy for philosophy. The principal manufactures are woollen goods, leather and toys. The trade is carried on by a number of barges, some of 250 tons. The exports are corn, cattle, wool, tobacco, and timber. Cattle are imported from Turkey, and salt from Transylvania. The town is surrounded by a mound and moat and is defended by a brick wall. Population, 26,000.

T.

TABASCO, river of Mexico in the state of Tabasco. This stream, as delineated on Tanner's Map of Mexico, rises in the mountainous chain between Guatemala and Chiapas, and flowing thence 150 miles, curves to the northeastward, enters Tabasco, and falls into the southern part of the Gulf of Mexico, after an entire comparative course of 300 miles, between latitudes 16° and 18° 30′ N.

TABASCO, state of the Republic of Mexico, bounded on the east by Sumasinta river, separating it from Merida or Yucatan; on the south it has the state of Chiapas; west the eastern extremity of Vera Cruz; and on the north the Gulf of Mexico. As laid down on Tanner's Map of Mexico, it is about 150 miles long from east to west, with a mean breadth inland of 60, area 9,000 square miles.

The declivity of Tabasco is to the northward, and drained in that direction by Tabasco, St. Pedro, and Sumasinta rivers. Lying between latitudes 17° 20′, and 18° 30′ N. and longitudes 14° and 16° 30′ W. from the meridian of Washington city. Population 80,000.

Hermosa, the capital, stands on Tabasco river about 40 miles inland from the Gulf of Mexico, N. Lat. 17° 46′; Long. 16° 37′ W. from W. C. Population 5,000.

TABASHEER, the name given to a siliceous substance of vegetable origin, which possesses very remarkable properties, both optical and physical. In the *Philosophical Transactions*, p. 1819, and in the *Edinburgh Journal of Science* for April 1828, No. xvi. p. 285, Dr. Brewster has given a full account of these properties, so that we shall content ourselves with giving a general abstract of them.

"Bamboo-manna" (says Dr. Wilson* the learned secretary of the Asiatic Society of Calcutta,) "is known in the Materia Medica of the Hindus by a variety of appellations, implying simply its being the produce of the bamboo, or denominating it from some of its sensible properties, the *milk*, *sugar*, or *camphor* of bamboos. The name in ordinary use is *Bansa-rochunu*, the ornament of the bamboo, corrupted in the vernacular dialect to *Bunslochan*. The name in use amongst the Mahommedans of India is *Tabasheer*, an Arabic word, explained by Meninski, *liquor, specie sacchari concretus in arundine Indica majore, et quasi petrefactus; in India, saccar Bambu* (sugar of the Bamboo,) *dicitur, pro quo cineres nodorum aut radicum vulgo distrahi solent*.

According to the Sanscrit works on medicine, such as the Bhava Prakas and Raja Nighant, the bunslochun is slightly austere, astringent, and sweetish to the taste. It possesses cooling and demulcent properties, allays thirst and fever, and relieves cough and difficult breathing. It sweetens the humours, and is serviceable in jaundice and leprosy. Its chief virtues, however, and those for which it is mostly esteemed, are supposed to be of a restorative nature, and it is highly apprized as an aphrodisiac.

In the markets of Calcutta it is found in three states. The best is termed *Patnai*, being brought from Patna, and is in small compact pieces of a milky-white colour, having the lustre of emanel, and being semitransparent. It is termed *Nilkunthi*, from its bluish tinge, and *Paharika*, from its being brought from the *Pahar*, or hills to the westward of Behar. The second sort is of a dead white colour, without lustre or transparency, and much more friable than the preceding. It is termed *Chheluta*, the Bengali corruption of Sylhet apparently, whence it is well known that this substance is procured. The third and worst kind is termed *Desi* or country; it is white; with a yellowish tinge, less friable than the second sort, but without lustre or transparency. The last is said to be soluble in water; the two first are not. An artificial bunslochun is also manufactured from chalk.

The following information respecting the Pharica or hill tabasheer, has been received from Captain Playfair, residing at Hazareebagh.

Bunslochun is found at Zelda, Boondoo, sixty miles from Huzareebagh, at Luka Kole, 100 miles from thence, at Palamow and at Nagpore.

It is found in the small hill bamboo. In a clump of fifty or sixty, only five or six contain the substance.

From each bamboo one or two rutties (four or five grains) are usually obtainable. It very rarely happens that four anas (from forty to fifty grains are procured.

It is found in the same bamboo of different qualities. The best sort is of a bluish white colour and glossy surface. An inferior kind is of a chalky white without lustre, and the worst sort is brown and even black.

The raw material is sold at ten rupees a seer; but it is prepared for use, and in that state sells from forty to fifty rupees per seer.

The only preparation, however, is its imperfect calcination.

A quantity is placed in an open vessel of baked clay upon a fire of charcoal, which is urged with bellows till the vessel and its contents become of a red heat. The manna first becomes black, but when raised to a red heat, emits a fine diffusible aroma.

It is kept red hot for some time, occasionally stirred with an iron spoon, and sometimes another vessel is inverted over that in which it is contained.

* In a MS. communication sent to Dr. Brewster, by George Swinten, Esq who has, at great trouble, sent him the finest collection of specimens of Tabasheers in existence.

The fire is then allowed to subside, and as it cools, the bunslochun resumes its white colour.

An ounce and a half, treated in this manner, was reduced to an ounce. The process lasted three quarters of an hour.

"The substance is sent to market in this state, and is taken in powder as a tonic, or chewed with betel, with a view to renovate the constitution."

As tabasheer, says Dr. Brewster, is found only in a small number of bamboos, (*arundo bambos*,) we cannot regard it as a secretion from the plant in a healthy state. An intelligent native of Vizagapatam, who had inspected several hundred bamboos, observed, that in every joint which contained the tabasheer there was a small perforation evidently made by an insect; and he conceives that the exterior juices of the plant find their way through this opening, and drying up form tabasheer. This observation, however, is by no means correct. I have found tabasheer in many joints where there was no perforation; and as the perforations are never lined with the siliceous matter, and have no accumulation of tabasheer at either end, they can have performed no part either in secreting or conveying the juices of the reed.

An examination of the joint or internode of the bamboo will probably lead us to a more satisfactory explanation. The culm or stalk of the bamboo represented by MN, Fig. 1, consists of a number of concentric rings. The outer rings, AC, BH, shown in section, are continued through the length of the reed, notwithstanding the little annular protuberance which marks externally the place of the internode AB. The inner rings, DE, GF, however, the innermost of which is a delicate membrane, do not pass onwards, but are interrupted by the internode, and turning round at EF, they form the roof of the cavity DEFG, joining the similar membrane on the side FG. Between AE and FB, where the concentric rings diverge, the space left between them is filled up with a soft spongy mass, which forms the substance of the internode AB. As the sap ascends between AC and ED, it must be stopped partially at the internode between A and E, part of it passing A, and part of it being either absorbed by the spongy mass between AE, and remaining there, or passing through it to the opposite side of the stem.

But, however this may be, the juices of the plant are collected at the internode, and could not possibly penetrate into the inner tube while the inner ring and membrane are sound, as in the healthy plant. When this membrane, however, is destroyed or rent by disease, or when the whole internode is in a state of mal-conformation, as I have found it, the juice or milk at the joints is immediately extravasated, lines the roof EF, or the bottom DG of the inner tube, and forms tabasheer by its subsequent induration.

The quantity of tabasheer, therefore, does not depend on the size of the reed, but upon the diseased state of its joints; and the greatest quantity was found in one where the internode is completely disorganized. Captain Playfair has mentioned four or five grains as the usual quantity. In the bamboo now alluded to the quantity is fully twenty grains.

By the cutting down and transporting of the bamboo, the tabasheer encrusted upon the roof or bottom of the cavity is detached, and is always found in separate pieces of different sizes. Its existence in any individual bamboo may therefore be known by the rattling noise which takes place by shaking the reed. A portion of it, however, often adheres to the place of its formation, and we may sometimes detect it in the pores of the spongy mass from which it has exuded. The largest piece of tabasheer are generally impressed with the inner membrane of the reed upon which it has been formed.

In opening different bamboos, the included tabasheer presents various appearances. When the tube has been perforated with holes, it has a brown dirty aspect, arising no doubt from the admission of dust; and the perforating insects are often found among the fragments. When there are no perforations, the tabasheer is clean and pure, presenting a great variety of aspects, depending probably on the nature of the juices, on the manner in which they have been extravasated, and on the time in which their induration has been effected. The different varieties of tabasheer may be thus enumerated.

1. The finest variety, which is also the rarest, is of a delicate azure blue colour by reflected light, and of a faint yellowish hue by transmitted light. It is easily crushed between the fingers, and it has an aerial and unsubstantial texture, which we look for in vain in any other solid. It has its counterpart in the mineral kingdom in some of the finer semiopals, which approach to the precious varieties.

2. Another variety of tabasheer reflects a yellow tint like that of molybdate of lead, and transmits a light of a reddish yellow tinge. It resembles greatly some of the yellow semiopals.

3. A third variety is nearly white, with a slight tinge of blue, and is translucent at the edge like cacholong.

4. A fourth variety resembles chalk, and is perfectly opaque.

Although these are the forms in which tabasheer generally occurs, yet several peculiarities of structure present themselves in the examination of numerous specimens. In some I have observed a layer exactly like jasper, and in one specimen the surface is covered with a brilliant enamel possessing all the lustre of pure quartz.

The chemical composition of tabasheer is still involved in some uncertainty. That which Dr. Russell brought from India in 1790, and which is similar to that sent by Mr. Swinton, consisted according to Mr. Smithson, of *pure silex;* but Fourcroy and Vauquelin* having examined a portion of what Baron Humboldt brought from South America in 1804, found it to consist of seventy parts of silex and thirty of potash. Dr. Turner,† who at Dr. Brewster's request, made a new analysis of the Indian tabasheer, found it to consist entirely of silica, with a minute quantity of lime and vegetable matter.

Its specific gravity varies from 2.060 to 2.190. The translucent variety of tabasheer loses 3.84 per cent. and the transparent variety 4.58 by a red heat, losses which it does not recover by exposure to the air.

It feels gritty in the mouth like magnesia, with a slightly nauseous taste. It dissolves readily in a solution of pure potash, even after being heated to redness.

When we plunge any of the varieties of tabasheer in water, an effervescence takes place, owing to the rapid escape of air from its pores; and when this has ceased, the transparent and translucent varieties have their transparency and translucency greatly increased, but the chalky kind retains its opacity. The quantity of water imbibed by the tabasheer exceeds in weight the tabasheer itself, and the space occupied by the pores is to that occupied by the solid particles nearly as $2\frac{1}{2}$ to 1.

The chalky tabasheer, which does not become transparent by the absorption either of oil of cassia or water, readily imbibes the fat oils, and with oil of beech-nut it becomes as transparent as glass, but it requires a considerable time to displace the air from its pores. These results are perfectly analogous to those which we obtain with hydrophanous opal, and I have also succeeded in giving transparency to the chalky silex from the Giant's Causeway, by long immersion in oil of beech nut.

If, instead of immersing the tabasheer in water, we place a small drop upon the most transparent variety, the drop is instantly absorbed, but the spot which it occupies becomes as white and opaque as if it had been covered with white lead. This extraordinary property, which is not possessed by any of the siliceous minerals, will be explained when we have treated of the optical properties of this substance.

The opaque tabasheer, which has become transparent by absorbing oil, exhibits a very curious phenomenon by change of temperature. If it is laid upon a piece of cold lead, it becomes suddenly opaque, and if it is restored to a warmer situation, its transparency as suddenly returns. These effects obviously arise from the great expansion and contraction of oil by heat. When the oil retreats from the surface of the specimen, the mutual attraction of its own particles accumulates them in one place, instead of permitting them to remain in a state of contraction in separate pores, as might have been expected. When the greater part of the oil has been expelled from these specimens by heat, the tabasheer exhibits a beautiful veined structure, the veins being sometimes parallel, as in the onyx, and sometimes curved, as in the agate. This effect arises from the different degrees of porosity in the different veins, in virtue of which some of them absorb more oil than others. The limits of each vein are thus rendered visible in the very same manner as the veins of burned chalcedony, which has absorbed oil from the lapidary's wheel, may be displayed in all their beautiful inflexions, although in its natural and transparent state it did not exhibit the slightest trace of such a structure. It is from the same property of some of the amorphous siliceous minerals that the lapidary is able to develope, and to colour, the veins of particular agates, and that the artist can execute the finest drawings, which actually lie beneath the surface of certain porous specimens of chalcedony.

The absorptive power of tabasheer is not confined to fluids. It draws into its pores solid bodies in a minute state of subdivision. If we wrap a piece of it in a bit of paper, and burn the paper, the tabasheer will come out of it of a glossy black colour, transmitting only red light, like a piece of smoked glass. By repeating this operation twice or thrice, it becomes so deeply black as not to admit a ray of the meridian sun. By exposing the specimen to a white heat the black matter is discharged, and the tabasheer is restored to its former appearance and properties. When the blackened tabasheer is plunged in water it disengages the included air, but with less rapidity than before, because there is less air to disengage; and when it is broken and pounded, its fracture and its powder are black. If the black matter has not insinuated itself copiously into the heart of the specimen, this portion is of a bluish slate-colour. When slightly wetted in this place it becomes *white*, and when saturated with water it becomes *jet black*. This, however, is an illusion; for though it does appear absolutely black, yet it is, in reality, made translucent by the absorption of the water. This translucency allows the white light, which the nucleus formerly reflected, to pass on to the black coating, where it is absorbed, —an effect analogous to what takes place in a black inkstand, in which it is impossible to distinguish ink from water by looking at the surface of the fluid.

One of the most remarkable properties of the tabasheer is its low refractive power, which is lower than that of any other body, whether solid or fluid, as will be seen from the following table:—

	Index of Refraction.		Index of Refraction.
Air,	1.000	Flint glass,	1.600
Tabasheer,	1.111	Oil of cassia,	1.641
Water,	1.336	Diamond,	2.470

Hence it appears, that the refractive power of tabasheer is actually nearer that of air than that of water. The index of refraction given above is the lowest that I have obtained; but specimens of greater specific gravity have higher refractive powers, as will be seen from the following measures:—

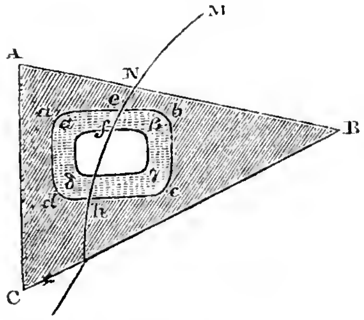
* *Mem. de L'Institut*, tom. ii. p. 382, an. 1806.

† Dr. Brewster's Journal of Science, No. xvi. p. 335, 1828.

Tabasheer,	1.1114	Tabasheer,	1.1503
do.	1.1145	do.	1.1535
do.	1.1292	do.	1.1825
do.	1.1454		

The specimen of tabasheer which I have described as covered with a brilliant enamel, possesses great hardness; and from the measure which I have taken of its angle of maximum polarization, I have no doubt that its refractive power approaches to that of the semiopals.

The determination of the low refractive power of tabasheer enables us to give a satisfactory explanation of the curious fact already mentioned, that a small drop of water produces white opacity, while a greater quantity renders it perfectly transparent. If ABC is a prism or piece of tabasheer, we may suppose one of its pores, highly magnified, to be represented by *a b c d*. This space is filled with air, and when a ray of light MN, enters the separating surface AB at *e*, and quits it at *h*, it suffers so little refraction, that the tabasheer allows us to see objects distinctly through it. Let us now suppose that a small quantity of water is introduced into the pore *a b c d*, so as not to fill it, but merely to line its circumference with a film which terminates at $\alpha\ \beta\ \gamma\ \delta$. Then the light which passes from water into air at *f*, and again from air into water at *g*, will suffer a comparatively great refraction, and will be considerably scattered in all directions. Hence the tabasheer must appear opaque. If we now saturate it with water, so as to fill the pore *a b c d*, the refractions at *f* and *g* are removed, and the ray *e f* will pass on to *h* unobstructed, so as to experience no change of direction, except the small one which takes place at *e* and *h*, where it enters and quits the fluid.



It may now be asked, whence comes the silex which circulates so abundantly in the juices of the bamboo? If we consult our best writers on chemistry and botany, we shall find it ranked as a "foreign ingredient," which the plant had derived from the peculiar soil in which it vegetated. Those who examined the drawings and descriptions of the distribution of silex in the *Equiselum hiemale*, which I submitted to the Society some years ago, will concur with me in the opposite opinion, that the silex is an integral portion of the plant itself, and probably performs some important function in the processes of vegetable life."

For farther information on this subject, see the *Phil. Trans.* 1790, p. 2739; 1791, p. 368; 1819, p. 283, Humboldt's *General Narrative*, vol. i. Introd. p. xiii. note, and Dr. Brewster's *Journal of Science*, vol. xvi. p. 285 and 335.

TABREEZ, or TAURIS. See PERSIA, Vol. XV. p. 455, and Kinneir's *Geog. Mem. of Persia*, p. 250.

TACITUS, CAIUS CORNELIUS, a celebrated Roman historian, was born about A. D. 57, at Interamna, now Terni. His father was procurator of Belgium, and so high was the reputation of his son, that in the twentieth year of his age, Julius Agricola gave him his daughter in marriage. He was successively Prætor and Consul; but history has not preserved either the circumstances or the time of his death. He lived on terms of the most intimate friendship with Pliny. His principal works are his "Annals," containing the History of Rome from the death of Augustus to that of Nero;—his History embracing a period of twenty-eight years, from A. D. 69 to 96; his Life of his Father-in-law, Cn. Julius Agricola; and his Treatise on the Manners of the Germans. The style of Tacitus is remarkable for its precision, its energy, and its dignity, and he is peculiarly entitled to the name of a philosophical historian. Among the best editions of Tacitus, are those of Rome, 1515, folio; of Gronovius, 2 vols. 4to. 1721; of Ernest, 2 vols. 8vo. Lip. 1752 and 1771; of Brotier, 7 vols. 12mo. 1776.

TACTICS, NAVAL.

We regret that our limits will not permit us to do justice to this very important subject, associated as it is with all that is glorious in our beloved country,—with the most illustrious names of modern times; and calling up in glowing colours the victories of St. Vincent, of the Nile and Trafalgar. Our continental rivals have long denominated us the giant of the seas. Our fleets have covered every ocean—the thunder of our floating bulwarks has resounded from every quarter of the sphere;—our gallant admirals have exemplified by a brilliant and continued practice, all that the most enlightened theories can teach; and there is hardly a page of our Naval History but is filled with achievements which have crowned our naval heroes with immortal honor and renown.

Naval tactics consist of such evolutions of a fleet, as shall at once insure its own safety, and under every possible condition, annoy and conquer the enemy. The writers on Naval Tactics have commonly laid down five orders of sailing, one order of battle, and one order of retreat. Of the five orders of sailing it may be remarked, that that is the best in which the course of the fleet is least impeded, and from which the desired order of battle can be the most readily and quickly formed, and as experience has proved the fifth to be the best, we shall introduce it to the reader's notice in Fig. 1, in which the fleet is divided into three columns, each of which is ranged in a line parallel to the close-hauled line upon which they are to form the order of battle. Generally the van-guard forms the weather column, commanded by the vice-admiral; the centre division commanded by the admiral, forms the centre column; and the rear guard commanded by the rear admiral constitutes the lee column. This arrangement, however, is sometimes altered for particular purposes. The genius of a Nelson cannot be cramped by arbitrary rules.

Order of Sailing.

It is obvious, that whatever order of sailing be determined on, in any case, the most rigid attention to its execution should be observed. The columns and the vessels, for this purpose, should preserve their proper distances. The commanders of each division, and each succeeding ship should keep themselves reciprocally abreast of each other; every vessel occupying, with respect to its immediate leader, the distance originally laid down by the admiral. It may be remarked, that the distance between the columns will be correct, if the first of any column, and the last ship of the next column form an angle of two points with the line on which they are moving. This order of sailing is preferred, because it unites all the advantages of the others, without their defects. The whole fleet is rendered more compact by it, signals can be better observed, and the order of battle can be more readily accomplished from it. It may be added, that in case of a very numerous fleet, the separate divisions may be formed into two or three columns, each chief being placed a little in advance of the middle of his own proper division. This arrangement is represented in Fig. 2.

It is an important object in this order of sailing, to regulate the distance of its columns. To determine this distance indeed, their length must be previously known. In Fig. 3, let the perpendicular CG be raised to the column CF, and equal to it in length. Join FG, and make FH equal to FC. Then will GH be the proper distance of the columns. This will be apparent, when we consider the van C, and the rear E to be equally to windward, and that EC is at right angles to the direction of the wind. The angle BFC being also 22° 30′, is the half of CFG; and, therefore, the triangles BHF and BCF are equal and similar; and BC equal to the intervals of the columns, is equal to BH or GH, according to the construction.

The same result may also be obtained by a numerical computation, by the following rule: *From the square root of double the square of the length of the column, substract the length of the same column, and the remainder will be the interval between the columns.* Or, as an approximate rule, the following is sometimes applied: *Take $\frac{5}{12}$ths of the length of the column, and the result will be nearly the distance of the columns.* These rules are illustrated in the following example.

Suppose a fleet to consist of three columns, and six ships in each column, to determine the proper interval of the columns, the distances between the ships being 100 fathoms, and the length of each ship from the jib-boom end, to the fly of the ensign 46 fathoms.

The length of the column in the present case will be 776 fathoms. Applying the first rule, its square will be 602176, and the square root of the double of this amounts to 1097. Subtracting from this last result the given length of the column, and there will remain 321 fathoms for the interval between the columns. By taking $\frac{5}{12}$ths of the length of the column, according to the second rule, there results 323 fathoms for the distance of the columns, which is sufficiently near for practice.

If the distances between the columns should at any time be given, the converse of the last rule will afford a ready method of determining the necessary lengths of the columns, viz. by multiplying the given distance by 12, and dividing the result by 5.

It may, however, happen that the columns have been already formed independently of the preceding rules, and that it is necessary to determine their interval. Suppose, by way of example, that a fleet consists of 12 ships in a column, and therefore of 11 intervals between the ships. Then we shall have,

	Fathoms.
12 ships at 46 fathoms each . . .	552
And 11 intervals at 100 fathoms each .	1100
The length of the column being therefore	1652

And to find the distance between the columns, let the bearings of the leading ship of one column, with the sternmost ship of another column be taken, and which may be denominated the angle of position. This may amount to thirty degrees, and hence we shall have, by the ordinary rules of trigonometry,

As the cosine of the angle of position, 30°	9.9375306
∶ the sine of the same angle	9 6989700
∷ the length of the column 1652	3.2180100
	12 9169800
	9 9375306
∶ the distance between the columns 954 fathoms	2.9794494

Our nautical friends will readily perceive that the same might have been worked by a traverse table, employing the length of the column as a difference of latitude, and the distance of the columns as a departure.

Order of Battle.

There is no method of preserving order in battles at sea, but by keeping upon a line, not quite close hauled, a-head of each other, and under very moderate sail. The distance between each ship varies according to circumstances, from one third of a cable's length to about 100 fathoms. Thus, in Fig. 4, let AB, A′B′ represent two hostile fleets drawn up in order of battle; CD, C′D′ their frigates and fire ships, the latter being distributed a-breast of the van, the centre and the rear, and protected a-head and a-stern by some frigates. These latter lines, it will be observed, are so arranged as to be to windward, when the enemy is to leeward, and *vice versa.* Beyond these are the two parallel lines EF, E'F', composed of hospital ships, transports, &c. and protected by frigates both a-head and a-stern.

The order of Retreat.

The order of retreat is seldom if ever rendered necessary to our gallant sailors, although the splendid retreat of Cornwallis affords a proof, that we have admirals who can conduct one with honour and success. Of course it can only be rendered necessary in the presence of a very superior enemy. The general principle is illustrated in Fig. 5, in which the fleet is arranged in two lines, AB, BC forming an obtuse angle, the admiral forming the angular point to windward, in the centre of his fleet. The frigates, fire-ships, transports, &c. are placed EF, FG, between the two lines to leeward. The course of a retreat is generally before the wind; but the fleet may go more or less large, according to the exigency of the moment.

To form and manœuvre the different orders without changing from or into another order.

It is a most important principle in naval tactics to become perfectly acquainted with the different methods of forming and manœuvring the several orders of sailing, without changing into another order; and many important advantages would result to the British navy by forming miniature fleets and squadrons of boats, and training the youthful aspirant for naval honours, to just perceptions of the nature of every evolution.

Our limits will only permit us to name the principal manœuvres connected with the fifth order of sailing with the figures which respectively illustrate them.

For a complete explanation of these refer to Steel's *Naval Tactics.*

Of keeping ships in their respective stations.

When an admiral, by signal, orders a particular manœuvre to be performed, it is the duty of every captain and inferior officer to see it carried into perfect execution, and to preserve his ship in the station that may be allotted to her, whatever may be the order of sailing determined on. For this purpose the naval-square has been contrived to assist our gallant seamen in their splendid duty. Suppose Fig. 15 to represent a horizontal section of a ship, and EF to represent a portion of the longitudinal axis running through the keel, and ABCD a square, formed so that EF may run through the intersection of its diagonals. Now the angles DGE and CGE are each twelve points or 135°, which is equal to the two courses close hauled on a wind. Let therefore these angles be bisected by the lines GH and GI, which will represent the direction of the wind, when close hauled, upon either tack. Hence, if a ship is running in the direction EF upon the starboard tack, her close hauled course upon the larboard tack will be in the direction of the semidiagonal GC. And if she be running in the direction of FE upon the larboard tack, her close hauled course upon the starboard tack will be in the direction of the semi-diagonal GD.

To apply this to the case of a fleet in three columns, close-hauled, the columns coinciding in the direction of the wind, in order to beat to windward with greater facility, let Fig. 16 be referred to, in which the naval-square is connected with the middle ship of the centre column. Then must the coinciding ships in the columns be kept in the directions GH or GI according to the tack and the wind; while the ships of each column must be in the direction of EF or parallel to it.

To form the line of battle.

Ships, from a variety of causes, are sometimes scattered, and therefore to form readily the line of battle is an operation of the first importance in naval tactics. The general principle is, for the ship which is destined to take the lead, to run to leeward of the whole, then to haul the wind, upon the tack directed, carrying an easy sail. Each of the other ships then makes sail, according to her distance, and chases the ship which is to be immediately a-head of her, and hauls in her wake, in the line on which the van ship is moving. Fig. 17 represents the case of a line of battle already existing, and in which it is required to form the line on the other tack without tacking in succession. This is performed by all the ships of the line veering together; the rear ship hauling her wind on the other tack, and standing on, while all the others go two points free on the other tack, and haul up, as they successively gain the wake of the leading ship. The rear ship thus gets into the van. For the line to veer in succession, the van ship veers round, and steers four points free upon the other tack, and when clear of the rear ship, she springs her luff, and gets close-hauled. The rest follow, and haul in succession.

It is also an important evolution in naval tactics to be able to interchange the different squadrons of a fleet with each other. Steel has given some interesting examples illustrating the interchange of the centre and van squadrons, the centre and rear squadrons, and the van and rear squadrons; how also the van may pass and form the rear, and how the rear may pass and form the van.

The most beautiful system of evolutions is developed, when an attempt is made to change from one order of sailing to another. We regret that our brief limits will only allow us to select two cases.

And *first*, to change from the fifth order to the line of battle on the same tack, the weather column passing to the rear. This is represented in Plate DXVIII,* Fig. 18, and to accomplish which, the lee column brings to, or keeps only steerage way, as close to the wind as possible. The centre column bears away together two points, and forms on the line a-head of the new centre squadron. The weather column veering together, and going seven points free on the other tack, will gain its station in the rear under an easy sail. Another case may be selected to change from the fifth order to the line of battle on the other tack. This is illustrated in Plate DXIX, Fig. 1, wherein the weather column begins the evolution by tacking in succession. The centre and lee columns stand on till their respective leaders can tack in the wake of the line, when they tack in succession. The two columns to leeward must carry an easy sail, lest they draw too near the rear of the weather column. Should that, however, be the case, the leader of the centre column must be careful and keep somewhat to leeward of the sternmost ship of the weather column, and the leader of the lee column must act in the same manner by the centre columns; or they may stand on beyond the wake of the column immediately to windward of them respectively, and tack to windward. They may then take their stations and form the line with facility.

Of manœuvring in the fifth order of sailing in six or nine columns.

On this important branch of the subject we can only briefly remark, that when fleets are numerous, their order of sailing is usually in six or nine columns, instead of three; that is, the van is divided into two or three columns, and so are the centre and rear. If the fleet be in six columns, the admirals place themselves abreast of each other, somewhat a-head and in the middle of the interval of their respective columns; or, if the fleet be in nine columns, they place themselves at the head of their respective centre columns. In either case, each squadron must manœuvre itself in the same manner as if it were in three columns. With a numerous fleet, many advantages result from increasing the number of columns, since the signals can be better seen, and every evolution can be performed in a less time, particularly in that important case of reducing it to the order of battle.

We select two examples by way of illustration. Let it be required to change from the line of battle to the fifth order of sailing on the other tack, the van squadron forming to leeward, the centre to windward, and the rear in the centre. This beautiful evolution is represented in Fig. 2, wherein the van makes sail, and tacks in succession; the column brings to, or carries a very easy sail. The leader of the centre column, which is now to form to windward, tacks as soon as the last of his column passes astern of the new lee column, and is followed in succession by his division. The leader of the rear, which is to form the centre column, tacks, either when abreast of the leader of the windward column, or when his centre ship passes astern of the lee column, or when he has the centre ship of the lee column in a line at right angles with the wind. When the rear has tacked, the lee column fills, and all the columns make the necessary sail, for regulating the order.

Secondly, let it be required to change from the line of battle to the fifth order of sailing on the other tack, the rear squadron forming to windward, the van squadron as centre column, and the centre squadron to leeward. This evolution is denoted by Fig. 3, in which the van and centre tack in succession, and pass on under easy sail. The rear, which is to be to windward, carries sail, and tacks in succession, when its leader has the headmost ship of the lee column in a line at right angles with the wind, or when its centre ship passes a-stern of the centre column. The columns then make suitable sail to regulate their distances.

To change and re-form upon changes of wind.

In the preceding inquiries, we have supposed the wind to remain constant, both in its intensity and direction; but we know that the best conceived plan of naval tactics may be rendered abortive by a change of condition in one of these causes. A sudden calm may render every ship motionless, or an alteration in the direction of the wind may require a new system of evolutions to be performed.

We must here limit our inquiries to the single but most disadvantageous change of wind that can happen to a fleet in a line of battle, and that is when it comes forward, the order being in such a case with difficulty reformed, particularly if the enemy be in sight. If the wind comes forward from one to six points, and it is intended to keep the fleet on the same tack, each ship having fallen off, the whole line brings to, excepting the headmost ship, which immediately bears away a certain number of points. This number of points is known by deducting from eight points one half of the points which the wind has changed; thus, if the wind has come forward five points, deduct half that number from eight, and the remainder five and a half points will remain, as the number the ships are to run large. The headmost ship then, having fallen off, and bore away, the ship which follows her fills and bears away as soon as she brings her leader to bear on the close hauled line. Each ship proceeds successively in the same manner, and in the end they altogether haul their wind in the wake of their leader, when they get upon the close hauled line with the sternmost ship, which then fills and stands on close hauled, not being under the necessity of bearing away. This is illustrated in Fig. 4. Steel gives some other methods of accomplishing the same object, some of which are advantageous, and others not, and to which we must refer our readers.

If the wind comes a-head more than six points, and less than twelve, the fleet, changing the tack, will manœuvre in the same way as if it had come a-head not more than six points. If two fleets are

* The number of this Plate (DXVIII) should have been placed immediately before "Fig. 1," in the second line of page 643, as all the figures mentioned in pages 643 and 644 (from Fig. 1 to 17 inclusive) have reference to it.

in sight in this case, that advantage of the weather-gage will be gained by the fleet that was before to leeward.

We must close this part of our subject with the interesting inquiry, how to change from the line of battle to the order of retreat, the wind coming forward. This may be done whether the wind come forward or aft, by first re-forming the line of battle, and then changing from that to the order of retreat. This is the most certain, but not the shortest method. It has, however, this advantage, that it does not so quickly communicate the intention to the enemy.

This double manœuvre requiring, however, considerable time, and as circumstances are not always favourable, it may be performed in the manner represented in Plate DXIX, Fig. 5, and which may be described as follows. The fleet having fallen off, the leader of the van goes four points free, while the rest of the ships stand on together close hauled, in order to gain the wake of the leader and each other respectively. When the centre ship has arrived at the angular point, that is, in the wake of his second-a-head, that wing is formed. The other wing will be easily formed, if (the first wing continuing to sail four points free) the ships of the other wing bear away four points free together, running on parallel courses with the first wing. The ships of the wing now forming must adapt their sail to place themselves on the proper line of bearing, which will be effected when each first, second, and third, &c. ship of one wing bears, from the corresponding ship of the other wing, in a line perpendicular to the direction of the wind.

Of cutting the enemy's line.

The splendid consequences that resulted from Lord Rodney's cutting the French line on the 12th of April 1782, afforded the most ample and satisfactory proofs of the advantages of the theory which Mr. Clerk of Eldin was the first to demonstrate as possible, and of which Paul Hoste seemed to have had some indistinct glimpses. We shall therefore conclude our paper by an account of the series of manœuvres which has rendered this battle so illustrious in the history of naval tactics.

On Monday the 8th of April 1782, signal was made from the British cruisers off Fort Royal Bay, Martinico, that the French fleet, attended by a number of transports, were then under way. The British fleet immediately weighed from Crosse Islet Bay, St. Lucia, and stood after them to the northward, under the west end of Martinico, and soon got sight of part of their men of war. The pursuit was continued, during the night, with all the sail that could be made, directed by the enemy's night signals, the wind blowing a fresh gale at N.E. by E. At two in the morning the Valiant, being to windward, discovered the enemy under the north end of the Island of Dominica. At three o'clock the fleet brought to by signal, the enemy at that time bearing nearly north.

In Fig. 6, A represents the British fleet at two in the morning of the 9th of April, discovering part of the French fleet, under the north end of Dominica at F. At three o'clock, brought to by signal; at half past five, the signal was thrown out to prepare for battle, the line to be formed at two cables length asunder, and the fleet to fill and stand on. G, the position of the French fleet at five in the morning, on the starboard tack, working to windward in the channel, between Dominica and Guadaloupe, where they had a steady breeze. H, one of the enemy's ships, at this time so far to leeward, that she must have been taken, had not the wind failed us, while she had it so fresh as enabled her soon to recover her station.

In Fig. 7, A represents the van of the British having at length gained the breeze, fetched up with the centre of the enemy, still upon the starboard tack, when they were fired upon about nine o'clock, and for an hour sustained a distant cannonade from as many of the enemy's ships as could be brought to bear upon them. The centre and rear of the British fleet was at this time becalmed under the island of Dominica, as B. F represents the French, not all in order of battle, some of their ships endeavouring to work to windward.

In Fig. 8, it will be perceived, that A, the centre of the British, having afterwards gained the breeze, joined the van about noon. The rear, which had been becalmed at C, at length got into line as D; and a cannonade continued for an hour and three quarters. F, the position of the enemy, who during all the time kept at such a distance as showed that they meant to disable,—a species of tactics which our opponents the French have too often showed for their own honour a determined disposition to persist in,—as soon as they saw the junction of the whole British fleet. Hauled off to windward, tacking from the van, as indicated by the course H H. At G will be perceived the enemy's fleet of transports, stretching away to windward of the Saints. The enemy did not at first appear to have suffered much; but soon after, one of them seemed to be crippled; and afterwards two of them were found to have received so much hurt, they were obliged to bear away for Guadaloupe to refit, and hence were not in the action of the 12th.

Fig. 9, denotes the British fleet on the morning of the 11th, having in view two disabled ships at G., under the island of Saints, and which were chased into Basse Terre, Guadaloupe. Soon after, two others were discovered far to windward, and disabled at H, near the north end of Dominica. A general chase was then ordered, four of the enemy's ships being at this time visible at I, from the Formidable's mast head, Lord Rodney's ship. On the Agamemnon and others, at B, coming near the ships at H, the French admiral, Count de Grasse, though far to windward, bore down as at F, to protect his two disabled ships. The Agamemnon and her consorts advanced in the pursuit; but upon the signal for all cruisers to return, they took up their proper positions in the line.

We now come to the splendid and eventful day of the 12th. At two in the morning, the British fleet being at A, Plate DXX, Fig. 1, after having run to the southward from B, their position the evening before, having taken advantage of the wind as at W, which generally hauls to the northward in the West Indies in the evening. At the last mentioned hour, having tacked to the northward, the French were discovered broad under their lee-bow, in some confusion at F. One of their ships was directly to leeward at G, with her bow-sprit gone, and her fore-mast across her fore-castle, towed by a frigate, the wind being E.S.E., as at Z.

At C, is represented the Monarch and Valiant going down from the rear to engage the disabled ship with her consort, which compelled Count de Grasse to edge down as at H, to their protection. The van of the British, about four or five o'clock, was at D, leading on the starboard tack; and the admiral, judging Count de Grasse might now have got so far to leeward, by the last mentioned movement, that it could not be possible for him to avoid an action, the Valiant and Monarch, the ships in chase, were ordered into their stations.

The French, aware of their situation, formed on a larboard tack; and the wind afterwards coming about from E.S.E. to nearly east, as at Y, they conceived hopes of gaining their usual fighting distance, more especially as their van at this time began to point to windward of the British.

The lines A and F, in Fig. 2, denote respectively the positions of the British and French fleets, at half-past seven in the morning, the Marlborough, the leading ship of the British van, having fetched the fifth* ship of the enemy's line. In this situation she was fired on, and the signals for close action and to close the line, were thrown out.

The consequence of the preceding manœuvre was a disposition resembling Fig. 3, wherein the van of the British fleet ranged slowly and closely along the enemy's line, each ship giving and receiving a heavy fire. The enemy's fleet at F, it will be perceived, had gained the wind, and were ranging in an opposite direction to our own. The British admiral's ship, the Formidable, having reached the enemy's fourth ship from their van, began a close action within half musket shot, continuing it close along the enemy's line, under an easy sail, till an opening appeared at the third ship astern of the French admiral, which afforded the opportunity of cutting their line in twain, completely separating the van from the rear, and forcing the headmost ship of their rear division, then coming up to leeward, as at G, thus affording a complete and triumphant proof of the accuracy of the principles that Clerk had so ably advanced. This is represented in Fig. 4, in which A is the Formidable, the British Admiral's ship; F the Ville de Paris, bearing the flag of the Count de Grasse; B the van of the British still ranging along the remaining part of the enemy's rear; C the rear of the British line following up after the admiral; H the last ship of the French van stretching past the rear of the British line.

In Fig. 5, the Formidable, Namur and Duke are shown at A, B, C, after having cut the line, and keeping up a powerful raking fire on the ships of the rear division of the enemy before forced to leeward, and which are now making the best of their situation by going off before the wind at G. F represents the van of the enemy, stretched past the rear of the British line, and preparing to break into two divisions. H denotes the middle division making to the west.

The subsequent positions of the two fleets become now of the greatest interest. So soon as the van division of the enemy had stretched past the rear of the British line, in bearing away, it broke into two divisions; one, consisting of seven ships, steering west as at H, Fig. 6, and which we may now call the middle division; the other taking a S.S.W. course, consisting of about 12 or 13 ships, and where Count de Grasse was himself, making the southern division of flight, as at F. A denotes Lord Rodney's ship, with part of the centre, putting about in pursuit of the enemy's van; and B, the rear of the British line, performing the same evolution. The signal for the rear to close with the centre being soon after made, both these divisions followed in pursuit of the southern division F.

The object now with the Count de Grasse, in the division last referred to, was to obtain a junction with the other divisions of the fleet at G and H. This was apparent by his abandoning his S.S.W. course, which he first pursued at Fig. 7, and turning his ship's heads to the northward as at F, and to form a new line of battle. A natural effect of this change, of course, was an alteration in the course of the centre and rear of the British fleet to the position AB, thereby causing the two divisions to approximate. The Count soon perceived this, and accordingly, at about two in the afternoon, he resumed his original direction as at I. The two fleets, therefore, at this moment occupied the following positions: A and B, the centre and rear of the British fleet, were in pursuit of the southern division of the enemy. The van of the British fleet continued in the same course as at C. The rear division of the enemy continued to advance to the westward, as at G; and the middle division of the enemy, not being pursued, repaired their damages under an easy sail.

Fig. 8 represents the two fleets again under the most interesting circumstances. The southern division at six o'clock, having been outsailed by their pursuers, turned their heads again to the northward, and the result was, that the centre and rear of the British fleet formed on each side of it. Five ships were taken from the enemy, the Ville de Paris striking at sunset to the Barfleur and Canada.† At this time Count de Grasse had got above five leagues to the westward and leeward of the field of battle; and night coming on. Admiral Rodney thought proper to give over further pursuit.

It may be necessary to add, that the rear division at G had, at this time, advanced above ten leagues to the westward and to the leeward of the field of battle; and that I, the middle division of the enemy, consisting of seven ships, having waited

* There is some little doubt whether it was between the third and fourth ship the line was cut, or between the fourth and fifth ships. It is however of little moment.

† Lord Rodney observes that the Count de Grasse in the Ville de Paris, behaved most bravely. His ship was entirely crippled, and three British Admirals were very near him, when he struck his flag. The French Admiral did all that so singular and unlooked for a circumstance as the cutting of his line in twain would permit.

for, rejoined the ships of the southern division, which afterwards effected an escape.

Such was the result of this new and splendid evolution. It may be asked, however, why did not the British admiral follow up his able attack, and make the signal for a night battle? He did so; but on looking about him—prudence in a conqueror being even much more necessary than in ordinary men, he observed that his fleet was greatly dispersed; that two of his 90 gun ships were greatly disabled; his own, the Formidable, greatly damaged; that his van and centre were also much hurt; that none of the prisoners from the captured ships were taken out;—that a very dark night of twelve hours was coming on—weighing all these—and the science of naval tactics is made up of contingencies—he thought it most prudent to make sure of the victory, and not run the risk of a reverse of fortune, or the danger of a night battle, wherein his own fleet might receive more damage from one another than from the ships of the enemy; that by running to leeward in the night, the enemy might deceive him, by ordering some of their frigates to hoist the lights of their admirals, and steer a course to lead the British admiral from them; and as the night was extremely dark, being the first day of a new moon, they might have hauled their wind to the north or to the south without being seen; at the same time they most carefully concealed all lights whatever. The British fleet, moreover, by pursuing, might have found themselves far to leeward in the morning, without the possibility of their getting to windward, by the crippled condition they were in. These reasons, and his experience of a night battle, induced the admiral to secure his splendid victory, and not to hazard a reverse of fortune. Rodney, therefore, made the signal for the British fleet to bring to, on the starboard tack, then so dark that one ship could not see another. Day light the next morning proved the wisdom of that signal; for, notwithstanding it was the duty of every ship to obey it, thirteen made sail, yet not one of them fired a shot, or came up with an enemy. This was a convincing proof of what might have happened had the whole fleet gone to leeward, and the enemy have hauled their wind; not only the captured ships might have been retaken, but some of the British crippled ships captured. Every sailor and man of science will acknowledge the wisdom of this decision.

Some of Mr. Clerk's observations on this splendid victory are deserving of much attention, and we shall therefore, introduce them to our readers. First, the difficulty will be remarked of an enemy's fleet making an escape to windward. Secondly, that the crippling of some of his ships will be a necessary consequence of the efforts made to effect this escape. Thirdly, that the protection given to ships crippled in consequence of these efforts, as it was the cause of bringing on the actions of both the 9th and 12th, and had nearly produced an action on the 10th, will also be a cause of bringing on an action on all future occasions of the like nature.

The attack made by the British in the action of the 9th, may be considered as an example of the simple attack, and shows how little may be expected from any rencounter between two fleets on the same tack, when an attempt shall be made from the leeward.

The judicious movement made by the British fleet, from a northerly course to a southerly one, on the night between the 11th and 12th, as it shows the advantage that may be made by a change of wind, at the same time shows the necessity of attention to such periodical changes. Indeed it was by this means only that the British fleet got within reach of the enemy on the morning of the 12th of April.

From the facility also with which Admiral Rodney's ship kept her wind, and forced her passage through the line of the enemy, and the necessary consequence that the headmost ships of the rear division must thereby be forced and driven to leeward, should with certainty establish, that breaking an enemy's line, by an attack from the leeward, is not only a practicable measure, but a measure attended with little additional danger or risk of shipping; and that with the same facility, and with equal probability of success, it might have been attempted, in former rencounters. And although Admiral Rodney, in either of his former rencounters of the 15th or 19th of May 1780, had not been convinced of the importance of this manœuvre—still, having been the first to put it in execution on the 12th of April, he has acquired a name renowned over the whole world.

The consequences resulting from cutting the enemy's line on this occasion, as they may be regarded as affording complete illustrations of the importance of Mr. Clerk's principles, may also be admitted as a proof of what ought to be expected in future on every similar occasion.

The hurry and precipitation with which the rear division of the enemy made their escape through the gap in the British line, as it showed their apprehension, should also be a proof of the danger of their situation.

The effort to escape, made by the van division of the enemy, as it confirms the general position, their desire of evading a conflict, confirms also the superiority of British seamen, which seems, indeed, to have been incontestible from the beginning of the whole affair to the end.

It must, however, be added, that the manner by which the van of the British was rendered almost without effect, shows that the rear division of the enemy, and not the van, ought to have been the object of pursuit. This is demonstrated by Clerk in his *Attack with the Centre*, part II. pages 180—183.

The proximity of the rear of the British to the rear division of the enemy, should sufficiently point out the object of pursuit they also should have chosen.

The British van and rear not having therefore been prepared to take advantage of their necessary mutual proximity to the rear division of the enemy, was a loss.

The rear division of the British also, by having been obliged to put about ship, in pursuit of the van of the enemy, already got some miles distant, is a full confirmation of the hypothesis laid down, that the pursuit of a rear division, cut off from the van of an enemy's fleet passing on contrary tacks, ought in general to be preferred.

Finally, the facility with which the rear of the British came up with the flying van of the enemy, shows that there was no inferiority in the sailing of the British ships.*

With this we most reluctantly close a subject which has much to recommend it to the attention of the young sailor; much to the higher officers of the navy, and much to the board of admiralty which presides over the naval destinies of the country. We might have added that there is much to recommend it even to the attention of the man of science, and to the historian, who may review the brilliant pages of our maritime exploits. To the young sailor, in particular, it will afford the most useful and salutary lessons, and prepare him for all the difficult and ever varying circumstances of his splendid profession. Nelson, amidst the fatigues of his arduous duties, found an agreeable relaxion in the important pages of Clerk,† and was perpetually forming schemes how he might successfully accomplish the conquest of an enemy, in every variety of position. The bright example of the immortal conqueror of the Nile and Trafalgar, ought ever to be present to the young officer's view. By making the subject of tactics a frequent object of contemplation, Nelson's energies were ever in action to meet the vicissitudes of his perilous duties. In whatever position he found the enemy, his ready and comprehensive mind seized all the great points of action, and having communicated his brilliant purposes to the captains of his fleet, stimulated the lowest sailor by the immortal signal, "ENGLAND EXPECTS EVERY MAN TO DO HIS DUTY."

TADCASTER, supposed to be the *Calcaria* of the Romans, a town of England, in the West Riding of Yorkshire, situated principally on the south side of the river Wharf, which is crossed by one of the best stone bridges in the country. The town is neat and well built, the streets being arranged in the form of a cross, and formed by the roads to York, Wetherby, Leeds, and Pontefract. The public buildings are an ancient church, an hospital for twelve persons, and a free school, both founded by Dr. Oglethorpe, and a respectable building for Sunday schools. There are some traces of a trench round great part of the town. The river Wharf is navigable to the bridge for sailing vessels, which supply the town with necessary commodities. Population of the township in 1821:—390 houses, and 1651 inhabitants. See the *Beauties of England & Wales*, vol. xvi. p. 621—629.

TAFILELT. See MOROCCO, Vol. XIII, p. 782, and BARBARY, Vol. III. p. 250.

TAGANROCK, a town of European Russia, on the N. W. coast of the Sea of Azof. It stands on the cliff of a lofty promontory; all the best houses are in the suburbs. It possesses a fortress, a harbour, a naval hospital, a lazaretto, and naval and commercial courts. It carries on an extensive trade. Its exports are caviare, butter, leather, tallow, corn, Siberian iron, fish, tar, and canvass. Its imports are fruits, Greek wine, shawls, tobacco, coffee, silk and precious stones. About 387 vessels, besides coasting ones, were employed in 1817. In 1817 the importation of foreign gold was 5,582,247 rubles, and merchandise to the value of 2,658,645. The value of the exports was 11,979,700, and of the imports 9,321,053 rubles. The town once contained 70,000 inhabitants, but now the population is only 6000. Dr. Clarke saw here people of 15 nations. East Long. 38° 39'. West Lat. 47° 12' 40''. See RUSSIA; also Clarke's *Travels*, vol. i. p. 327, and Rordanz's *European Commerce*, pp. 660 and 670.

TAIN, a royal burgh and county town of the shire of Ross, is situated on the south side of the firth of Tain or Dornoch, which separates Ross from Sutherland. It is conjectured that the name is derived from the term *Thane*, as the Thanes of Ross are said to have occupied the adjacent lands. As the town is situated in a Gaelic district, it has also a particular name in that ancient language. Some derive its appellation in Gaelic, *Baldhuich* or *Baile Dhuthuich*, from *baile*, a town with a combination of letters resembling the names of *Duthas* or *Duthac* annexed, and literally signifies the town of Duthas. This derivation is rendered probable from the ruins of a small chapel in the immediate neighbourhood, called *St. Duthas Chapel.* To this chapel it is said "king James IV., in way of penance, travelled on foot from Falkland, with uncommon expedition, resting only a short while at the monastery of Pluscardine, near Elgin." Others spell the name of the town Ball'n 'dhuic, which literally signifies the county town. But the Gaelic tongue seems so flexible, that derivatives from it cannot be much depended on. The oldest charter extant, confirming the rights of Tain, and dated 1587, was given by king James VII., and it is there stated that the ancient charters of the burgh were burnt by some Irish rebels. From an inquest dated 20th April 1439, held for the special purpose of ascertaining the antiquity and liberties of the burgh of Tain, it "was found that all the inhabitants within the aforesaid liberty of Tain, and all their goods whatsoever, are under the special protection of the Apostolical See, and that the said immunity was first founded by the deceased most illustrious king of Scots, Malcolm Canmoir of blessed memory." The town is small, and, like most old towns, is built without much regard to regularity. The population is at present somewhat less than 2000, but is gradually increasing. There are no manufactures of any consequence carried on in the town, and the trade consists chiefly in

* Much has been said on the inferior construction of British men-of-war. How comes it that we have conquered so many of our opponents, under circumstances so exceedingly diversified?

† We recommend Admiral Ekins's Naval Battles to the attention of our readers, excepting some of his remarks relating to Clerk.

supplying the country with goods brought from a distance. This want of manufactures may, in some measure, be accounted for, from the want of a proper pier where goods might be landed with safety. Notwithstanding this want of trade, the state of the town and country is such as to support two thriving branches of the British Linen Co. and Commercial banks. There is a good jail here, and an excellent building for debtor's rooms and courts of justice have lately been annexed to it. There is a large and commodious church here, sufficient to accommodate all the regular hearers in the parish. The people are very much attached to the established church; and what is very singular, there is scarcely a dissenter in the whole parish. In the old church, which is still a fine old building, there is a very curious carved pulpit which was presented by the regent Murray to the town of Tain.

By the exertions of a few public spirited gentlemen connected with the county, an excellent academy was, in 1813, established by royal charter at Tain, in which the fundamental branches of classical literature and science are taught by a rector and three teachers. It is impossible to observe the numerous and great improvements which have taken place in Tain within the last sixteen years, without connecting them with the establishment of this institution, which will prove one of the greatest blessings conferred on this part of the country, and will transmit to posterity the names of its founders as the greatest benefactors of the county of Ross. (W. R.)

TALAVERA, an ancient town of Spain, in New Castile. It stands on the Tagus, which is crossed by a bridge of 36 arches, and 1200 feet long. It contains some good churches, four hospitals, and a classical and theological academy. The manufactures are silk, soap, hats and earthenware. Population about 800.

TALAVERA, Battle of. See Britain, Vol. IV. p. 684.

TALBOT, county of Maryland, bounded S. and SE. by Choptank river, separating it from Dorchester county, Maryland; E. by Choptank and Tuckahoe rivers, separating it from Caroline county; N. by Queen Anne county; and W. and SW. by Chesapeake bay. Greatest length almost exactly on one degree E. of the meridian of Washington city, and from the southern angle on Choptank river 25 miles, to the northern angle on Queen Anne. The western part is so much indented by small bays extending inland from Chesapeake bay as to render the mean width difficult to determine, but the aggregate land area being 250 square miles, the mean breadth will be about 10 miles. It lies between Lat. 38° 34′, and 38° 56′ N. and between Long. 0° 42′ and 1° 10′ E. from W. C.

The whole county is a peninsula between Choptank river and Chesapeake bay, but is again cut into three minor peninsular sections by Choptank, Tread Haven, and St. Michael's bays. Surface generally flat, but with a slight southern declivity. So much is it indented by small creeks or inlets, that it is probable not a single point within its boundaries is three direct miles from a navigable water.

By the post list of 1831, Talbot county had post offices at Easton the seat of justice, and at St. Michaels, Trop, and Wye Mills.

Easton, the county seat, stands near the head of Treadhaven bay, about 50 miles SE. from Baltimore, by post road; 47 miles SE. by E. from Annapolis, and 84 a little S. of E. from Washington City. N. Lat. 38° 46′, and Long. 1° E. of the meridian of Washington City. Easton is a seaport and considerably the largest town of the eastern shore of either Virginia or Maryland. Population, 1830, 12,947.

Whether the discrepancy arises from a defective mode of taking the census, or from a real diminution, the population of Talbot county of Maryland appears to have decreased in the decennial period from 1820 to 1830; as at the former epoch the aggregate was 14,389, but at the latter, only 12,947, showing a difference of 1442.

TALBOT, county of Georgia, bounded by Marion county S.; Muscogee SW.; Harris W.; Merriwether NW.; and by Flint river separating it from Upson, NE. and Crawford E. The greatest length from the extreme eastern angle on Flint river, to the northwestern between Harris and Merriwether 47 miles; and the superficial area being 600 square miles the mean width is about 13 miles.

This county extends from Lat. 32° 35′ to 32° 54′, and in Long. from 7° 10′ to 7° 54′ W. from the meridian of Washington City.

The western and southwestern parts reach over the summit level between Flint and Chattahooche, and give source to brief streams flowing westward into the latter river; the body of the county, however, has an eastern declivity towards the Flint.

It is a county of recent formation, and by the post list of 1831, had only two post offices; one at a place called Liberty, and the other at Talbotton, the seat of justice. As laid down on Tanner's United States, Talbotton, the seat of justice in this county, is situated on a small creek of Flint river, and stated in the post office list of 1831 as 112 miles distant from Milledgeville. On Tanner's Map the distance is about 90 miles in a direction SW. by W. from Milledgeville to Talbotton.

TALLAFERRO, county of Georgia, bounded N. by Oglethorpe county; NE. and E. by Wilkes; SE. and S. by Hancock, and W. by Greene. Length from south to north 17 miles; mean width 8, and area 136 square miles. Lying between latitudes 33° 28′, and 33° 43′ N. In Long. the 6th degree west from the meridian of Washington traverses it and divides it into two not very unequal portions.

Declivity to the southeastward and drained in that direction by the higher confluents of Little river and Great Ogeechee river. According to Tanner's United States, this is the least extensive county of Georgia, and by the post office list of 1831, had only one post office, that of Crawfordville, the county seat, which, as laid down by Tanner, is situated between Little river and Great Ogeechee river, and by the post road, 47 miles NNE. from Milledgeville, and 52 miles a little N. of W. from Augusta. N. Lat. 33° 32′. Long. 5° 58′ W. from Washington City.

TALLAHASSE, post town, seat of justice for Leon county, and seat of government for the territory of Florida, is situated about 30 miles inland and north of St. Mark's Bay of the Gulf of Mexico; about 50 a little E. of N. from Ocklockonne Bay, 200 miles NW. by W. from St. Augustine, a similar distance a little N. of E. from Pensacola, and by calculation on Mercator's principles, S. 36° 10′ W.; 725 statute miles, but by post road 896 miles from Washington City. N. Lat. 30° 27′; Long. west from W. C. 7° 30′.

Tallahasse is recent in its foundation, the first buildings were erected there during the summer of 1824. The first legislature which sat in this new born city held its session in the winter of 1824-5. In 1825 it was incorporated a city. So rapid was the augmentation of its population, that when John Lee Williams published his "*View of West Florida*" in 1827, he estimated the inhabitants at 800.

Mr. Williams concludes his notice of Tallahassee by observing,—"Few towns in America have increased more rapidly; and population and improvement continue without any abatement. It might in a few years become a charming place of residence, though it will probably never become a place of great commercial importance."

Judge H. M. Brackenridge, from personal observation, thus describes the valley of Tallahasse.

"Instead of being a plain of unvaried surface, it resembles the high lands above the falls of the rivers in the Atlantic states, and is beautifully diversified by hill and dale, and rendered picturesque by the number of lakes, whose pure waters reflect the forests of oak which frequently clothe the sides of the hills, down to their very margins. These lakes receive a number of streams, which flow from the higher grounds and loose themselves in their placid bosoms. The largest of them are called the Iamony, Jackson, and Mickasukey, but there are many others of a smaller size, affording many beautiful situations for country residences, where the naturally open groves of oak, hickory, beech, and magnolia grandiflora, surpass in magnificence the proudest parks of the English nobility. The soil of the uplands bears a strong resemblance to the best part of Prince George's county, Maryland; and the face of the country is not unlike the south side of the Potomac near Washington City. In the vallies there is a much heavier growth of timber, and frequently deep cane-brakes. There are also frequently to be met with, grassy ponds, surrounded by glades, which afford excellent pasturage.

"The only regret which I feel in contemplating this beautiful region, is its very limited extent—an Oasis, which appears to have been formed by nature in one of her most sportive and fantastic humours. The general substratum, perhaps a few feet above the level of the sea, is a soft limestone of recent formation. In the pine wood plain, which stretches towards the high lands of Tallahasse, the stone is often found in masses on the surface.

"By the last census (1826), Tallahasse contained about eight hundred inhabitants, and five or six mercantile establishments, which do an extensive business. The country begins to wear the appearance of cultivation; good roads are made in all directions, and carts, wagons, and carriages are constantly travelling them."

With due allowance for a natural warmth of description in the accounts given by emigrants into a new country, we may regard Tallahasse and the immediate vicinity as a delightful section of the southern part of the United States, but as Judge Brackenridge acknowledges, it is an Oasis.

TALLAPOOSA, river of the United States in Georgia and Alabama, rises by two branches in the Cherokee territory of the former state, and flowing thence southwestward, traverses Carroll county, and entering Alabama, bends to SSW., the two forks uniting, and the latter course continued about one hundred miles over the Creek territory, to near the eastern border of Montgomery county. At the latter point the stream abruptly bends to the west, and pursues that general course 25 miles to its junction with the Coosa at or near Coosauga, to form the Alabama. The entire length of Tallapoosa, by comparative courses, is about 150 miles, but the mean width of its valley does not exceed 25: area about 3750 square miles, and lying between 32° and 34° of N. lat., and between the valleys of Coosa and Chattahooche rivers.

TAMBOURING. A full account of this manufacture, and of Duncan's Patent Tambouring Machine, was given by the inventor of the latter, in the Article CHAINWORK, Vol. V. p. 588, 597.

TAMWORTH, a borough and market town of England, in Staffordshire, situated at the conflux of the Thame and Anker, the former of which divides the town nearly into two equal parts. The town is large and well built, and its principal buildings are two stone bridges, a fine church, several meeting-houses, an hospital, a grammar school, and an old castle. Its manufactures are superfine narrow woollen cloths. Calico printing, tanning, and brewing are carried on to a considerable extent. It sends to parliament two members, who are chosen by about 250 voters. The population of the borough and parish in 1821 was 7185.

TANGENCY. See FLUXIONS, Vol. IX. and TRIGONOMETRY.

TANGIERS, anciently TINGIS or TINJA, is a seaport town of Fez in Morocco, situated at the western entrance to the Straits of Gibraltar. The bay, which is defended by five old batteries, is encumbered by the ruins of the moat and fortifications which were destroyed by the English in 1686. The town subsists chiefly by supplying Gibraltar with cattle and vegetables. W. Long. 5° 50′. N. Lat. 35° 42′.

TANGIPAO, or as usually pronounced, Tanzipaho, river of the United States in the states of Mississippi and Louisiana, has the most remote northern sources in Amite and Pike counties of the former, from whence it flows SSE., and entering Louisiana, separates the parish of St. Helena from that of Washington and St. Tammany, finally falls into the northern side of Lake Pontchartrain, after a comparative course of between 70 and 80 miles.

In the higher part of its course within the state of Mississippi, the valley of Tangipas lies between those of Amite and Bogue Chitto; but in the lower section within Louisiana, between the Chifuncte and Tickfolah vallies.

TANNIN. See CHEMISTRY, Vol. V. chap. VI. sect. III. p. 702, 703. See also p. 756.

TANNING is the art of converting into leather the gelatinous parts of the skins of animals by impregnating them with tannin. The skins chiefly employed are those of bulls, oxen, cows, &c. which are converted into leather for the soles of shoes, and those of calves, seals, &c. which are converted into leather for the upper leathers of boots and shoes, saddles and harness. The method of manufacturing these different kinds of leather is as follows:

1. *Method of manufacturing butts or barks.*—The heaviest and stoutest of the bull and ox hides being selected for the purpose, they are allowed to lie in a heap for two or three days, and are then hung up on poles in the smoke house, kept, by means of a mouldering fire, at a temperature somewhat above that of the atmosphere. A slight putrefaction takes place, loosens the epidermis, and renders it easy to separate the hair and other extraneous matter from the true skin, by the *fleshing knife*, with which it is scraped on a convex board, called a horse. The hides thus cleaned are then *raised* or steeped in water containing a little sulphuric acid. The effect of the acid is to distend the pores of the skin, and prepare it for the reception of the tanning.

The hides are now removed to a pit, and laid one above another, with a stratum of powdered oak bark below each, and the pit is filled with the tannin lixivium or ooze prepared from oak bark and water. Here they remain for a month or six weeks, at the end of which they are taken out and replaced with fresh bark and ooze. After remaining three months, the operation is repeated three times or oftener at the same intervals. When they have thus sufficiently imbibed the tannin, they are suspended in a shed to dry, and when compressed with a steel instrument, and rendered firm and clean by beating, they are ready for sale, and are used for the thickest sole leather.

2. *Method of manufacturing crop hides.*—The hides are immersed for three or four days in pits containing a mixture of lime and water, being occasionally stirred up and down. When the extraneous matters have been removed by the flesh knife as above described, they are worked in water. They are now immersed into a weak ooze, and gradually removed to other pits with stronger ooze, being moved up and down, or *handled*, as it is called, once every day. At the end of a month or six weeks they are put into pits with a stronger ooze and a little powdered bark, and the process is repeated with fresh ooze and bark for two or three months. They are then put into larger vats, called *layers*, in which they are laid one above another in an ooze of still greater strength, and with a large quantity of good bark interposed. They remain here for six weeks, and they are then taken up and relaid with strong ooze of fresh bark for two months. This process may be repeated once, twice or thrice, according to circumstances, and when it is completed, the skins are taken out, dried, and smoothed as before. The sole leather used in England consists of the crop hides.

3. *Method of manufacturing the skins of calves and seals, &c.*—Hides of this description are kept in the lime pits for ten or fifteen days: the hair, &c. is then removed, and they are steeped in an infusion of pigeon's dung, called a *grainer*. Here they are frequently tumbled about and taken out and scraped, and at the end of a week or ten days they are removed into pits containing a weak solution of bark, where they go through the same process of handling, &c. nearly as crop hides, though they are seldom put down in layers. This operation lasts from two to four months. The skins are then dried, and the currier dresses and bleaches them for the different purposes to which they are to be applied. For farther information on this subject see "Dr. Macbride's paper, *Philosophical Transactions*, vol. ix. p. 111," vol. LXVIII, and that for 1803. See also Newton's *Journal of the Arts*, Jan. 1829, p. 219, for an account of a powerful tanning lixivium used in America, by J. Giles. It is announced in the Journals that M. Rapedius has discovered that 3½ lbs. of the bilberry or whortleberry plant, (*vaccinium myrtillus*) will tan a pound of leather which requires 6 lbs. of oak bark. This important experiment has been successfully tried at Treves.

TAPESTRY. See our article FRANCE, Vol. IX. p. 427. See also *Phil. Trans.* 1731, vol. xxxvii. p. 181, and Duhamel, *Art de Fair de Tapis.*

TAPPAHANOC, post village, and seat of justice, Essex county, Virginia, situated on the right bank of Rappahannoc river, by post road 109 miles a little E. of S. from Washington City, and 50 miles NE. from Richmond. N. lat. 37° 58′, long. 0° 10′ E. from the meridian of W. C. The site is low and flat, and in summer the inhabitants are liable to agues and fevers. It is, however, a place of considerable trade, as even large merchant vessels can ascend far above. The harbour at Tappahanoc is about 50 miles above the open Chesapeake bay.

TAR, a dark brown resinous juice, distilled from the pine. The Baltic tar, with which Great Britain is supplied, is thus made. Pine branches cut into billets are built up on the slope of a hill, in large stooks, and covered with turf; they are then set on fire, and while they burn with a smouldering flame, the tar formed by the decomposition of the resinous juice, which runs to the bottom, flows through a small channel, by which it is collected and put into barrels.

The Switzerland tar is formed by heating billets formed from the trunk of the tree freed from its bark. The ovens, which are about ten feet high, and six in diameter, are made of stone or brick like an egg placed on its small end, and a gun-barrel is fixed at its lower end, to carry off the tar. The oven is charged by bundles of billets, the interstices being filled up with chips, and a layer of chips being laid uppermost. It is then covered in with flat stones, forming a kind of vaulted chimney. The dry chips at the top are set on fire, and the chimney being entirely closed up with a large stone, wet earth is heaped on the stones at top, and constantly applied wherever the smoke is observed to issue. The general product is about 10 or 12 per cent. of tar, of the weight of the whole charge. The red wood and knots are found to furnish about one fourth of their weight in tar.

An account of the quantity of tar obtained by the destructive distillation of coal, will be found in our article Gas Lights, Vol. IX. p. 581.

TAPAJOS, or as pronounced according to English orthography, Tapahos, great river of South America, interlocking sources about Lat. 12° 30′ S. with those of the Guapare branch of Madeira, and with the extreme northern sources of Paraguay river. Assuming thence a course of N. N. E. upwards of nine hundred miles, falls into the Amazon, at Santerem, S. lat. 2° 20′.

The valley of the Tapajos lies between those of the Madeira and Xingu, and in an imperfectly explored region.

TAR, or as named in the lower part of its course, Pamlico, river of the United States, in North Carolina, has its most remote north-western source in Parson county, interlocking sources with those of Hycootee branch of Dan river, and with those of Neuse river. Flowing thence south-eastward over Granville, Franklin, Nash and Edgecombe counties, it receives a large northern branch, Fishing creek, from Warren and Halifax counties. At its reception of the water of Fishing creek, Tar river has flown by comparative courses about ninety miles, and thence with an extensive sweep to the southward, the original general course is maintained forty miles to the head of Pamlico bay, at Washington, in Beaufort county.

The Tar river valley, including that of Pamlico bay, is about one hundred and sixty miles in length, with a mean width of thirty miles, and lying between those of Neuse and Roanoke. Extending in Lat. from 35° 15′ to 36° 25′ N. and in Long. from 0° 25′ E. to 2° 15′ W. of the meridian of Washington city. It is navigable for vessels of nine feet draught to Washington, and for river boats to Tarborough, at or near the confluence of the two main branches.

TARBOROUGH, post village and seat of justice, Edgecombe county, North Carolina, situated on the right bank of Tar river, below the influx of Fishing creek, by post road, 72 miles a little N. of E. from Raleigh, and 252 a little W. of S. from W. C. N. Lat. 35° 53′, Long. 0° 36′ W. Darby.

TARASCON, a town of France, in the department of the *Bouches du Rhone*, situated on the Rhone opposite Beaucaire, with which it has a communication by a bridge of wood. It possesses several handsome churches; but the castle, a large building of hewn stone, and fortified in the Gothic manner, is the principal edifice. Woollen and cotton goods are manufactured, and a trade is carried on in wine, olive oil, and brandy. It is the chief place of the *Isle de la Camarque*. Population about 18,300.

TARBES, anciently Bigorre, a town of France, and the capital of the department of the Upper Pyrenees. It consists chiefly of a single street, in a beautiful meadow on the left bank of the Adour. The streets are tolerably broad, and the houses, which are of brick or gray marble, and slated, are not ill built. The cathedral, the churches, the episcopal palace, the theatre, and the hospital, are the principal edifices. The town is defended by a wall and an old castle. Paper and linen articles are manufactured here. Population about 8000.

TARES. See Agriculture, *Index*.

TARN, a department in the south of France, bounded by those of the Avignon, Lot, the Herault, &c. Its surface is a gently undulating plain, crossed by several chains of small hills. It derives its name from the Tarn, which rising in the department of Lozere, and traversing that of the Avignon, flows through the department into the Garonne. It is well watered by the Agout, which passes Castres, and falls into the Tarn below Lavaur. Its chief towns are,

	Population.
Alby, the capital,	9,649
Castres, - -	15,386
Gaillac, - -	6,465
Laveur, - -	6,237

There are here some mines of iron and coal, and a little silk is raised. Wheat, barley, maize, hemp, flax, and wines, are its chief productions. The forests occupy about 90 thousand acres. The contributions in 1803, were 2,693,820. The superficial extent of the department is 576,821 hectares. The population in 1822 was 313,713, and in 1827, 327,665, and the number of inhabitants for every 1000 hectares, was then 560. It contains about 50,000 protestants.

TARN and Garonne, a new department in the south of France, formed in 1808 out of part of the departments of Lower and Upper Garonne. The surface is a plain traversed by three chains of hills, the highest of which does not exceed 1200 feet. The productions are wheat, barley, maize, hemp, flax, wines, chesnuts, almonds and figs. Montauban is the capital. The superficial extent is 354,591 hectares. The population in 1822 was 238,143, and in 1827, 241,586, and the number of inhabitants to every 1000 hectares was 670.

TARQUIN. See Roman Empire.

TARRAGONA, a seaport town of Spain in Catalonia. It is situated near the mouth of the river Francoli upon a hill, and is defended by turreted walls. It has a large and elegant Gothic cathedral, with a magnificent chapel built with rich marble and jasper in honour of St. Thecla. Population about 7500.

An account of Sir J. Murray's descent upon Tarragona will be found in our article SPAIN in this volume. See also BRITAIN, Vol. IV. p. 706.

TARTAGLIO, NICHOLAS, an eminent Italian mathematician, was born at Brescia about the beginning of the 16th century, and died at Venice in 1557. An account of his labours and writings will be found in our articles GEOMETRY, Vol. IX. p. 653, and MATHEMATICS, Vol. XII. p. 439.

TARTARY, a name given to a very extensive tract of country in Central Asia, bounded by Arabia and Russia on the north, and the confines of China, India, and Persia on the south. It is divided into two great portions, *Independent Tartary* and *Chinese Tartary*.

Independent Tartary is bounded on the south by Balk and Khorasan in Persia, on the west by the Caspian, and on the north by the provinces of Oufa, Orenburg and Tobolsk in Asiatic Russia. The principal kingdom of Independent Tartary is Great Bucharia, which we have already described. The Khirghises occupy a great extent of territory on the north, and are divided into the Great, the Middle, and the Lesser hordes. The Great horde is estimated at 60,000 families, and the other two at 30,000 each, so as to give a population of above half a million. They live in huts and lead a wandering life, each horde being governed by a Khan. They occupy the whole country from the north end of the Caspian to the Talkan Lake. The Uzbeck and Turcomans occupy the vast sandy desert between the Aral and the Caspian, and the country on the upper Oxus. On the Taxartes, there is a fertile and thickly peopled territory belonging to the bey of Koukan, but very little is known of it. For farther information respecting this part of Tartary, see AFGHANS, ARAL, BALK, BUCHARIA, CABUL, CASPIAN SEA, SAMARCAND. See also PERSIA and RUSSIA.

Chinese Tartary embraces an immense extent of country of about 70 degrees of longitude, and 20 of latitude. It includes, on the north, Mongolia and Mandschuria; on the west, Cashgar; on the south, Thibet; and in the centre the territories of the Calmucks or Eluths. As almost nothing is known of the present state of these hordes, we must refer our readers to the articles BUCHARIA LITTLE, Vol IV. p. 773; CALMUCKS, Vol. V. p. 174; CHINA, PERSIA, and THIBET. See also ASIA, Vol. V. p. 513; PHYSICAL GEOGRAPHY, Vol. XVI. and RUSSIA, Vol. XVI, p. 519.

TASSO, TORQUATO, a celebrated Italian poet, was born at Sorreno on the 11th March 1544. At a school of the Jesuits at Naples, to which he went at the age of five, he made such rapid progress, that in the 7th year of his age he recited compositions of his own, both in prose and verse. At the age of 12, he entered the University of Padua, and so premature was the development of his intellectual faculties, that in his 17th year he received degrees in canon and civil law, philosophy, and divinity. Invited to Bologna by the celebrated Cesi, his talents became very conspicuous; but having composed a defamatory poem, he was deprived of his books, and thought it prudent to retire to Castelvetro, under the patronage of Count Rangoni. In 1562, at the age of 18, he published at Venice his poem of *Il Rinaldo*, a work on the plan of the Odyssey, which he dedicated to Cardinal D'Este, in consequence of which he was invited to the Court of Ferrara, where he is said to have carried on his great work of the *Gerusalemme Liberata*, six cantos of which were composed in his 17th year. In the year 1571, he accompanied the cardinal to the Court of Charles IX. of France, where he was well received; and, on his return in 1572, he caused his dramatic pastoral of *Aminta* to be represented. About this time seven cantos of his Jerusalem Delivered, which had been lent to his friends in MSS., were copied and disseminated through Italy; and in 1577, the 4th canto was printed at Genoa in a poetical collection. In 1580, portions of 16 cantos were printed at Venice; but in 1581 there appeared three editions of this great work, the last of which, published at Ferrara, is regarded as the most genuine.

The circumstances which led to this carelessness respecting his works sprung out of a mental disease under which he doubtless laboured. This state of mind has been ascribed to a rash affair of love which touched the honour of the family of Alphonso, Duke of Ferrara, and which terminated in the confinement of Tasso in a lunatic hospital by the order of that prince. After his liberation, he lived at Rome with Cardinal Cinzio Aldrobrandini, who obtained a pension for him from Pope Clement VIII. In this retreat, in 1593, he published his *Gerusalemme Conquisita*, which is a sort of recomposition of his former work. This zealous patron had arranged a solemn poetical coronation of the poet in the capitol, but his own illness interfered with the immediate execution of the plan, and an attack pregnant with danger disabled Tasso from receiving so high an honour. He was removed to the convent of St. Onofrio, where the consolations of religion were administered to him by his affectionate friend, and where he died full of piety and hope in April 1595, in the 51st year of his age. A monument was erected to his memory in the Church of St. Onofrio, by Cardinal Bonifacio Bevilacque.

Tasso was in person tall, active, and well proportioned. In society he was silent, grave, and polite, and kind and affectionate in all his social relations.

Besides his Jerusalem Delivered, and the other works already mentioned, he wrote his *Sella Giornata*, or works of the seven days, which relates to sacred subjects, the tragedy of Torremond, and a great number of treatises, dialogues, and letters on various topics.

Lord Byron has done honour to the memory of this great poet by his "Lament of Tasso," published in 1817, and to which he has prefixed the following notice:—"At Ferrara (in the library) are preserved the original MSS. of Tasso's Gerusalemme, and of Guarini's Pastor Fido, with Letters of Tasso, one from Titian to Ariosto; and the ink-stand and chair, the tomb and the house of the latter. But as misfortune has a greater interest for posterity, and little or none for the cotemporary, the cell where Tasso was confined in the hospital of St. Anna attracts a more fixed attention than the residence or the monument of Ariosto; at least it had this effect on me.

"There are two inscriptions, one on the outer gate, the second over the cell itself, inviting, unnecessarily, the wonder and the indignation of the spectator. Ferrara is much decayed and depopulated; the castle still exists entire; and I saw the court where Parisina and Cluzo were beheaded, according to the annal of Gibbon."

TASTE. This subject has been discussed so amply under our articles Beauty, Vol. III. p. 363–371, and under the Principles of Civil Architecture, Vol. VI. p. 414—423, that there is no occasion to resume it under the present head.

TAVISTOCK, a borough of England, in Devonshire, situated on the Tavy, over which there are two bridges. The church is spacious, and consists of four aisles, a chancel, and a tower raised on arches. It contains some bones of gigantic size that were found among the ruins of the abbey. The chief manufacture is that of serges. It is one of the Stannary towns. It sends to Parliament two members, who are chosen by about 110 votes. Population of the borough and parish in 1821, 5483.

TAUNTON, a borough of England, in Somersetshire. It is situated on the banks of the Tone, and consists of four spacious streets containing many good houses. In the market place, which is large and handsome, there is an appropriate market house and town hall. It contains two parish churches, and five dissenting meeting houses. The church of St. Mary Magdalen is a beautiful building, with a lofty dome 183 feet high, remarkable for its magnificence and elegance. The church of St. James is a plain but ancient building. There is here a free grammar school, two large alms houses, and an excellent hospital, built in 1772—1779. It sends to Parliament two members, who are elected by about 500 votes. Its manufactures consist of coarse woollen goods, silk, and ale. The ale is in high esteem. The Tone is navigable for barges to Bridgewater. There is here a theatre, and races are held near the town. A newspaper is published at Taunton. Population of the borough in 1821: Inhabited houses, 1503; families, 1706. Total population, 8534.

TAUNTON, Vale of. See England, Vol. VIII. p. 502.

TAUNTON. Capital of Bristol county, Massachusetts, on the west side of Taunton river, 21 miles east of Providence and 36 south of Boston. It is a pleasant town. Population in 1830, 5798. In 1652, the first extensive iron works in North America were erected in this town. The nail factories, when in full operation, can now turn out from eight to ten tons of cut nails per day. The first shovels that were made in this country were made here. Most of the bricks for this section of the country have long been manufactured in this town—between eight and nine million are now made annually. There are in the place seven cotton factories; two breweries; two printing offices, from which are issued two weekly newspapers and two juvenile papers; one rolling and slitting mill; one forge; one shovel manufactory; one copper and lead rolling mill; one paper mill; one carding and fulling mill. The calico establishment furnishes from 4000 to 5000 pieces per week, in a style equal to any manufactured in the country. There is also a manufactory of Britannia ware. We believe it is the only establishment of the kind in the country. It is about three years since it was commenced on a small scale. It is now grown into an extensive business. The ware is now pronounced, by competent judges, to be far superior to the imported article. It has already made its way into public favour; and the "Taunton silver" is now to be seen in most of our large cities, rivalling, in beauty and brightness, the standard metal. We ought not to close this article, without mentioning the court house, the stone church, and the Episcopal church, as being ornaments to the village; the last we believe to be unrivalled in this country for neatness and picturesque beauty. Darby.

TAYLOR, Brook, an eminent English mathematician, was born at Edmonton near London in 1685. In 1701 he was entered a fellow commoner at St. John's college, Cambridge; and in 1708, in the 23d year of his age, he wrote a paper on the Centre of Oscillations, which is published in the Phil. Transactions for 1713. In 1709 he became LL.D., and in 1712 he was elected a fellow of the Royal Society, and in the same year communicated to them his curious experiment on the hyperbolic figure of water ascending between two glass planes. In 1714, when he had taken his degree of LL.D. at Cambridge, he was elected secretary to the Royal Society; and in the Transactions from vol. xxvii. to vol. xxxii. he published several excellent papers, principally on mathematical subjects. His principal works, however, are his *Methodus Incrementorum*, and his treatise *On the Principles of Linear Perspective*, both of which appeared in 1715. The first of these contains a curious theorem for expressing a variable quantity by all the orders of its differentials, and also a paper on the vibrations of a tense cord, in which he first established the isochronism of a vibrating string.* His Treatise on Perspective, which was reprinted with improvements in 1717, was the first in which this art was established on infallible principles.

In his intense application to study he lost his health, and was obliged to repair to Aix-la-Chapelle. On the death of his father in 1729, he succeeded to the family estate of Bifrons, in Kent; and in the year following he lost his wife in childbed. About this time he composed his *Contemplatio Philosophica*, the work of a Christian and a scholar, which was published by Sir. W. Young in 1773. He died of consumption in October 1731, in the 46th year of his age. His grandson, Sir W. Young, published his posthumous works, with a life of the author prefixed.

* See our article Acoustics.

TAZEWELL, one of the south-eastern counties of Virginia, bounded on the north by the Tug Fork of Sandy river, separating it from Logan county; north-east by Giles; east and south-east by Walker's mountain, separating it from Wythe; south by Clinch mountain, separating it from Washington; south-west by Russell, and west by Floyd county of Kentucky. Length from west to east 80 miles; mean width 20, and area 1600 square miles. Extending in Lat. from 36° 54′ to 37° 32′ N. and in Long. from 4° to 5° 12′ W. from W. C.

The central part of this county is a very elevated mountain table-land. The eastern part declining northeastward, and drained by confluents of Great Kanawha; the southern section gives source to Clinch and Holston rivers, the extreme northern constituents of Tennessee river. The western and much the most extensive section declines northwestwardly and discharges in that direction the extreme highest sources and branches of Sandy river.

Compared with the ascertained elevation of the water in Great Kanawha at the influx of the Greenbrier river, which is 1333 feet above the ocean level, the lowest elevation than can be given to the central mountain vallies of Tazewell must be 1500 feet, and the mean relative height of the arable soil of the county must be, at the lowest estimate, 1200 feet of similar relative height. This comparative height is equivalent to four degrees of latitude, therefore if we allow 37° 13′ as the central latitude of Tazewell we have 41° 13′ N. as about the mean of its winter climate, when compared with the Atlantic coast.

By the post office list of 1831, there were but three post offices in this large county. These were, Tazewell court-house, the seat of justice, Bluestone and Burkesgarden.

Tazewell court-house, or as named and laid down on Tanner's United States, Jeffersonville, is situated at the foot of Rich mountain, on the height of ground between the extreme source of Clinch river and that of Bluestone branch of Great Kanawha, about 150 miles northeast by east from Knoxville in Tennessee; and by post road 352 miles southwest by west from W. C., and 290 a little south of west from Richmond. N. lat. 37° 5′, Long. 4° 30′ west from W. C. In 1820, the space since laid out and formed into Logan county was included in Tazewell, and jointly contained 3919 inhabitants. DARBY.

TEA is the name given to the leaves of the Tea tree, an infusion of which in boiling water is now a favourite beverage among all civilized nations. The natural history of this valuable substance has been so fully detailed in our article CHINA, Vol. VI. p. 166---167, that it is unnecessary to resume the subject.

Nothing is more remarkable than the rapid progress of the tea trade, as appears from the following tables:

	Tea imported.		Tea imported.
1700	91,183 lbs.	1706	137,748 lbs.
1701	66,738	1707	32,209
1702	37,061	1708	138,712
1703	77,974	1709	98,715
1704	63,141	1710	127,299
1705	6,739		

During 100 years from 1710 to 1810 inclusive, there were sold at the East India Company's sales 750,219,016 lbs., the value of which was £129,804,-595; of the above quantity 116,470,675 lbs. were exported, and the remainder 633,748,341 retained for home consumption.

The following table, which has just been published, brings down the state of the tea trade in Britain to the present year.

Years.	Quantities retained for Home consumption. Lbs.	Net revenue of Customs and Excise. £	s.	d.
1789	14,534,601	562,038	14	5
1790	14,693,299	547,230	4	8
1791	15,096,840	607,430	8	4
1792	15,822,045	616,775	6	9
1793	15,244,931	609,846	5	6
1794	16,647,963	628,081	6	5
1795	18,394,232	695,108	5	9
1796	18,009,992	877,042	13	0
1797	16,368,041	1,028,060	9	7
1798	19,566,934	1,111,898	9	1
1799	19,906,510	1,176,861	9	9
1800	20,358,702	1,152,262	0	0
1801	20,237,753	1,287,808	2	6
1802	21,848,245	1,450,252	7	9
1803	21,647,922	1,757,257	18	4
1804	18,501,904	2,348,004	4	8
1805	21,025,380	2,925,298	17	4
1806	20,355,038	3,098,428	13	2
1807	19,239,312	3,043,224	11	3
1808	20,859,925	3,370,610	0	10
1809	19,869,134	3,130,616	14	9
1810	19,093,244	3,212,430	1	1
1811	20,702,809	3,249,294	0	9
1812	20,018,251	3,258,793	2	9
1813	20,443,226	Custom House records destroyed.		
1814	19,224,154	3,428,236	8	4
1815	22,378,345	3,526,590	18	3
1816	20,246,144	3,956,719	0	5
1817	20,822,936	3,003,650	18	7
1818	22,660,177	3,362,588	10	1
1819	22,631,467	3,256,433	12	10
1820	22,452,050	3,128,449	17	0
1821	22,892,913	3,275,642	17	6
1822	23,911,884	3,434,292	19	10

1827	26,043,223	3,263,206	19	3
1828	*26,790,481	3,177,179	8	0

Those who wish for farther information on this subject, will find an excellent account of the rise, progress, and present state of the tea trade in Milburn's *Oriental Commerce*, vol. ii. p. 520—542. See also Staunton's *Embassy to China*. Appendix to Dr. Latham's *Natural History of the Tea Tree*, 1772. See also ALIMENTS.

TECHE, river of Louisiana, rising in the northern prairies of Opelousas, N. Lat. 30° 40′. The

* This amount includes all tea shipped to Ireland for consumption in that country subsequently to the passing of the act 9th Geo. IV. cap. 44.

drains of these savannahs, after flowing 7 or 8 miles, divides into two channels; one flows northwardly into the Courtableau river, whilst the other pursues a southeastern course. This remarkable separation of currents is about half a mile below the upper Opelousas landing; and from thence the southeastern branch takes the name of Teche. Flowing between waters of the Courtableau and Vermilion rivers 10 miles, it receives an inlet from the latter under the name of Bayou Fusillier. The peculiar structure of the country, and the very near approach of the surface to a plain, is seen in these interlocking water-courses.

Below the influx of Bayou Fusillier the Teche leaves Opelousas and enters Attacapas; and in the residue of its course presents a stream with great specific resemblance to the Mississippi in the Delta. Though on a very reduced scale, the Teche, similar to its immense prototype, flows in long sweeping bends, with its banks above any other part of the adjacent country, the channel being the deepest valley. The adjacent water-courses rise from the very margin, and in a distance, following the channel, of 180 miles, the Teche receives no tributary stream.

With slight selvedges of woodland immediately on the stream, prairies extend along the entire right bank of Teche, and for more than one half of the higher part of its course, also along the left bank of this interesting river. The border sloping very gently from the high bank, from a quarter to a mile in width, is composed of the very first rate land, between latitudes 29° 44′ and 30° 40′ N. Below Lat. 30°, the climate admits sugar cane, and near the mouth a few orange trees begin to appear.

It is impossible to carefully examine the Teche without a conviction, that the time was when a much more extensive mass of water must have passed down a channel so very deep and wide as to appear out of all proportion to the quantity of fluid it now contains at any season of the year. The high margin of Teche may be regarded as the western boundary of the overflow of Atchafalaya and Mississippi combined; but from the colour of the alluvial banks of Teche it is more than evident that the waters of Red river, or at least a part, once passed down its channel—a phenomenon which has now entirely ceased.

Thus distinguished by peculiar features, the Teche, after a comparative course of 120, but if the actual course is pursued, falling little short of 200 miles, falls into Atchafalaya. Any vessel which can enter the latter over its outer bar, can ascend the former to New Iberia at the head of tide water. It may be noticed as a very characteristic feature of this part of Louisiana, that though the tides of the Gulf of Mexico do not exceed a mean of 2½ feet, yet that they ascend so deep into the country. Pursuing the channels of the two rivers, New Iberia is not much if any less than one hundred and fifty miles from the open Gulf. To New Iberia, which is a port of entry, vessels of 7 feet water can be navigated in perfect safety.

Articles of export from this river are chiefly cotton and sugar. Neat cattle are reared in great numbers in the adjacent prairies, but are in most part driven alive to the New Orleans market. DARBY.

TEHERAN. See PERSIA, Vol. XVI. p. 459—466.

TEIGNMOUTH, a seaport town of England in Devonshire, is a celebrated watering place situated at the mouth of the river Teign. It stands on a gentle eminence, and is divided by a rivulet into E. and W. Teignmouth, which form two parishes. The public assembly and billiard rooms form a handsome building in E. Teignmouth; and the theatre, which is in W. Teignmouth, is a neat structure. The church of E. Teignmouth is an old and respectable building situated near the sea. That of W. Teignmouth is a handsome octagonal building finished in 1821. A commodious market-place has been lately erected. The principal trade of the place consists in the exportation of pipe clay and the importation of coals, and in a commercial intercourse with Newfoundland. The ships employed are chiefly built here. The population of the two parishes in 1821 was 769 houses, 855 families, and 3980 inhabitants.

TELEGRAPH.

TELEGRAPH from τηλε *at a distance*, and γραφω *to write*, is the name given to a piece of mechanism for the rapid communication of intelligence by signals.

When we find that some of the most savage nations of modern times are acquainted with the use of signals, it would be absurd to suppose that the civilized nations of antiquity had not devised and put in practice regular methods of communicating intelligence both by fires during the night, and by movable objects during the day. The Prophet Jeremiah vi. 1. directs the children of Benjamin "to set up a sign of fire at Beth-haccerem, as evil appeared out of the north and great destruction;" and Eschylus, who lived about two centuries later, makes one of the soldiers in his *Agamemnon* descend from a watch tower at the top of the palace and announce from the fire signals the fall of Troy long before the return of the Greeks.

Polybius gives a full account of the πυρσειαι or fire signals of the ancients, and describes his own improvements on the method of telegraphic communication invented by Cleoxenus. Kircher in his "*Ars magna*," &c. distinctly describes a telegraphic experiment, and Schottus in his *Technica curiosa* proposes the application of the telescope to view posts erected upon an eminence. The Marquis of Worcester in Nos. 6 and 7 of his *Century of In-*

ventions enumerates a day and night telegraph among his contrivances: and Kessler in his *Concealed Arts* proposes to cut out characters in the bottom of a cask having a light placed within it, the characters being changed in succession in order to express single words, and whole sentences.

The earliest telegraph for general purposes appears to be that of our celebrated countryman Dr. Hooke, who has described it in the *Philosophical Transactions* for 1694. This contrivance consisted of more than thirty different bodies, each of which formed a distinct telegraphic sign or symbol, which were exhibited in succession upon an elevated apparatus. This apparatus, shown in Plate DXXI, Fig. 1. consists of three long masts or poles, two of which carry a screen A, behind which the thirty bodies hang upon rods or lines. These bodies, consisting of squares, centres, triangles, and made of deal, may, by the help of small lines connected with them, be exhibited at B, where a square is shown. In the night time torches, or other lights, were arranged in a particular order, and were substituted in place of the wooden figures. The characters, which thus represent the alphabet, may be varied, as Dr. Hooke observes, in ten thousand ways, whilst none but the two extreme correspondents shall discover the information conveyed.

Long after the publication of Hooke's contrivance, M. Amontons, an ingenious natural philosopher and member of the Academy of Sciences, brought forward, and submitted to trial, a plan of a telegraph which seems to differ in no respects from that of Dr. Hooke. He proposed to place the stations at such a distance that a telescope could command them. The signals to be seen through the telescope were either to be large letters of the alphabet, or figures to represent them, and he appears to have tried the plan before several persons of distinction in the court of France.

In the year 1767 R. L. Edgeworth, Esq. made trial of a new method of carrying intelligence. He made use of a common windmill for the purpose, and he arranged a system of signals produced from the different positions of the arms carrying the sails, the canvass being removed from one or more sails as the circumstances might require. In 1784 the same ingenious author brought forward his plan of a numerical telegraph, the signals denoting numbers, and each party having vocabularies in which all the words were indicated by the number which the signals represented.

Notwithstanding these various attempts to contrive and construct telegraphs, yet the practicability of these machines does not seem to have been distinctly recognised till the year 1794, when the activity of the National Convention called into play all the talents of the kingdom. M. Chappe* had the merit of introducing, on this occasion, under the name of the *Semaphore*,† what has been called in England the T telegraph, from its resemblance to that letter. It is represented in Fig. 2, where CD is a strong wooden mast carrying a beam AB, called the long indicator, which can be placed in any position round C as a centre of motion, by means of cords and pulleys. This indicator, which is about twelve feet long, and nine inches broad, carries at each extremity two lesser indicators AE, BF, which are likewise movable round A and B as centres, so that they can be placed in any position with respect to the long indicator AB. Each of the lesser indicators can obviously take five distinct positions with respect to the great one considered as fixed, viz. two at right angles to AC, two inclined 45° to AC, and one where it falls back upon AC and appears, so that we have thus $5 \times 5 = 25$ signals. But as AD may distinctly take four positions, one horizontal, one vertical, and one inclined 45° to the horizon, we have $4 \times 25 = 100$, for the number of distinct signals given by the semaphore.

In the semaphore constructed at Paris the first station was on the Louvre. The distance of the stations was three or four leagues, and an observatory was erected near the committee of public safety, to observe the indications on the Louvre. Although the semaphore of M. Chappe possesses great power, yet it is said to have been liable to mistakes, unless when wrought by experienced operators.

In 1794, Mr. R. L. Edgeworth proposed the telegraph shown in Fig. 3, which consists of four separate pointers, having the form of an isosceles triangle, with their base rather less than half the perpendicular, and movable round centres at the top of the vertical posts A, B, C, D. The four pointers are placed in a row, and the right hand one D represents *units*, the next C *tens*, the third B *hundreds*, and the fourth A *thousands*. Now each pointer can take *eight* distinct positions; seven of these denote figures, and the upright position of the pointer represents *o*, or zero. With the figures, as thus indicated by the telegraphs, are contained a vocabulary, with numbers opposite the words.

The Rev. Mr. Gamble produced, in 1795, plans of two telegraphs which are represented in Figs. 4 and 5. The first of them consists of five boards, one above the other, which, by opening and shutting, afforded a certain number of distinct signals. His second plan consisted of five beams of wood, each ten feet long. All the five moved round a common centre of motion, and as those motions were independent of each other, *one*, *two*, *three*, or *four*, could be exhibited at different degrees of elevation, in reference to a horizontal line, or with respect to each other, so as to furnish a great number of signals. One of these was erected in 1803, on one of the towers of Westminster Abbey, but has been long ago taken down.

In 1808 Major C. Le Hardy described a telegraph consisting of four pointers, or long arms, each carrying at its extremity a square wooden board. One of these represents units, another tens, another hundreds, and the fourth thousands. The indices move on a common centre, and each index board is placed at a different distance from the centre of motion, so

* M. Dupuis is said to have invented a telegraph in 1781.

† From σημα, *a sign*, and φερω, *to bear*.

that in turning round, these boards describe four circles of different radii. The inclination of the arm to the horizon indicates the number, and each has ten different positions. In order to identify these positions, a large frame, with ten radical bars, is fixed behind the pointers, and these are crossed by five circles, corresponding to the bulk of each index board.

Among other contrivances, similar to this in principle, may be numbered that of Dr. Garnet, who proposed to read off the inclination of the pointers to the horizon by a wire in the focus of a telescope, which, by turning the end of the tube brings the wire in a line with the pointer, (see Fig. 6,) and indicates its inclination upon a scale.

In 1795, Lord George Murray laid before the Admiralty his plan of a six shutter telegraph, which is shown in Fig. 6. This plan was in use during the whole of the late war, but in 1816 was replaced by a simplified semaphore.

The first French semaphoric telegraph which is said to have been erected on the palace of the Thuilleries in 1796, is shown in Fig. 8.

In the year 1796, Mr. Edgeworth proposed to simplify this telegraph, by using only one of the masts and one of the isosceles triangles, shown in Fig. 3, and at the same time proposed a two-armed telegraph, one of the arms having the form of a cross, and the other, that of a wood-cutter's sign, as shown in Fig. 9.

In the year 1798, MM. Breguet and Betancourt presented to the National Institute a new telegraph on a simple construction. It consisted only of a single piece, called the arrow, and one of whose extremities was terminated in a T, in order to distinguish it from the other end.

At the beginning of the war in 1803, there were erected a series of telegraphs along the coast upon the same principle as the radiated telegraph of Mr. Gamble. Each telegraph consists of an upright post, as shown in Fig. 10, carrying three arms exactly similar to each other, and each moving round an axis of its own. The distance between the centre of motion of two contiguous arms is a little less than double the length of one arm. The uppermost arm exhibits seven distinct positions, and the others have only six each.

One of the most ingenious and ardent improvers of the telegraph, is our countryman Colonel Pasley, who published in 1810 an account of the polygrammatic telegraph for day signals, which he had invented in 1803. He proposed to erect four posts, with arms complete, at every signal station, as shown in Fig. 11. In 1810, he described another on a new construction, shown in Fig. 12. This is precisely similar to the first, excepting that the pairs of arms used are placed upon one lofty post, instead of several short ones.

Considering the shutter principles inferior to that of the Semaphoric arms, Colonel Macdonald proposed in 1808, the machine shown in Fig. 13, the construction of which, and the reason for adopting it, are thus given by himself. "As *three* shutters give only seven mutations, it was found necessary to have recourse to *four*, which furnish *fifteen* changes. The four shutters were placed in a frame over each other, and worked in the usual manner. Shutters 1, 2, 3, and 4 shut in succession, for the highest gave numerals 1, 2, 3, and 4. To have the remaining numerals, it was requisite to combine or to exhibit two shutters closed together, or at the same time. Thus shutters 1 and 4 gave numeral 5. Shutters 2 and 4 closed, expressed numeral 6. Shutters 3 and 4 closed, yielded figure 7. The two upper shutters closed, represented numeral 8. Shutters 1 and 3 closed, denoted figure 9, and the two middle shutters closed, represented the 0 or cypher. As four shutters, acting as above, in a frame, would furnish a telegraph capable of giving only *one figure at a time*, it was requisite to have three conjoined frames, with four shutters in each frame, in order to be enabled to have the places of *units*, *tens*, and *hundreds;* or in other words, to be able to express any *three* figures *simultaneously*. On this simple principle I constructed my *twelve shutter telegraph for fixed stations*. Four of the five of the remaining combinations in each of the three sets of co-operating sets or frames, are given by exhibiting three shutters closed, as shutters 1, 2, and 3; 1, 2 and 4; 1, 3 and 4; 2, 3 and 4; the last or fifteenth mutation being furnished by closing all the four shutters. * * * There is a circular board over the middles or *tens-set* of shutters, and the application of it doubles power in particular instances, and is otherwise essentially beneficial."

In the year 1816, Sir Home Popham, who had distinghished himself by his improvements on navy signals, introduced a new semaphore, which was adopted by the Admiralty and substituted in place of the shutter telegraph. It is shown in Fig. 14, and is nothing more than two arms moving round separate centres upon the same post.

In 1818 Lieut. Colonel Macdonald invented and described a ball and six shutter telegraphs calculated to express any three figures simultaneously. It has an auxiliary ball above the middle row of shutters, and is surmounted by a semaphore for expressing the classes of words. The same ingenious author invented in 1817 a six ball and three figure telegraph, which gives 4095 combinations, and when conjoined with two of the semaphoric powers, not less than 1,048,575 combinations. See Fig. 16.

The most recent, and probably the best of all the telegraphs that have yet been proposed, is the Universal Telegraph, invented in 1822 by Colonel Pasley, who has given the following description of it:—

For the day signals the telegraph consists of an upright post of moderate height, of two movable arms fixed on the same pivot, near the top of it. and of a mark called the indicator on one side of it. See Fig. 17.

Each arm can exhibit the seven positions 1, 2, 3, 4, 5, 6, and 7, exclusive of its quiescent position, called "the stop," in which it points vertically downwards, and is obscured by the post. Fig. 17 represents the telegraph exhibiting the sign 17, the other positions, of which the arms are capable being dotted. The indicator merely serves to distinguish the low numbers 1, 2, and 3, from the high numbers 7, 6, and 5, so that this telegraph is not, like most others that have been proposed, liable to ambiguity or error, when viewed from different points in contrary directions*.

The use of the indicator will appear more evident on considering the resemblance between the small Roman letters b and d, or p and q, which if viewed in contrary directions, like telegraphic signs, could never be distinguished, one from the other, without some additional mark.

Fig. 18 represents the telegraph fitted up for making nocturnal signals. One lantern C, called the central light, is fixed to the same pivot, upon which the arms move. Two other lanterns are attached to the extremities of the arms. A fourth lantern I, used as an indicator, is fixed on the same horizontal level, with the central light, at a distance from it equal to twice the length of one arm, and in the same plane nearly in which the arms revolve. Hence the whole apparatus consists of two fixed and of two movable lights, four in all.

The number of telegraphic signs, combinations, or changes, which this telegraph is capable of exhibiting, are only 28, but these are amply sufficient for every purpose of telegraphic communication, whether by the alphabetical method, or in reference to a telegraphic dictionary of words and sentences. These signs are represented in Fig. 21, showing the appearance of the same combinations both by day and night.

In some few of the nocturnal signs, it will be observed, that one of the lights is marked black. This only happens when one of the movable lanterns is supposed to be in its quiescent position, hanging vertically down below the centre light. In this case, as the lantern may be exhibited on either side of the post, in may sometimes be seen, and sometimes not, by the distant observer. At first I proposed to interpose a couple of screens, one on each side of the post, to hide the lanterns altogether when in this position. Afterwards that idea was abandoned, it having been found, in practice, that it made no difference in regard to the clearness of the signs alluded to, whether the movable lanterns were seen or obscured, when in the position denoted by the black circles.

The indicator, both by day and night, being merely a mark and nothing more, which, when once seen, requires no farther attention to be paid to it; and the central light by night, and the post by day, being also merely guides to the eye; the signs of this telegraph are, in reality, composed of the combinations of two movable bodies only by day, and of two movable lights only by night, being the smallest number of parts, with which an efficient telegraph can possibly be formed: and in this diminution of the number of combinable parts, as well as in the unity of plan, consists the superior simplicity of this telegraph, as compared with other efficient telegraphs that have been proposed.

The arms and the indicator for the day signals are made of wood, framed and pannelled, for the sake of lightness. The indicator plays in a mortise, cut in the upper part of the post, and is let down into its horizontal, and raised into its vertical position, by means of a small rope, and a small pulley. The arms must be fixed externally, one on each side of the post, and must be exactly counterpoised, by means of light frames of open iron work, which become invisible by day, at a little distance, and which, even when viewed closely, do not impair the clearness of the telegraphic signs. This precaution is absolutely necessary, otherwise the arms will not remain in any given position, without being held by the hand, or stopped by some mechanical contrivance, which would be a very great inconvenience in the practice of signal making.

Motion may be communicated to the telegraphic arms, by means of an endless chain, passing round, and acting upon a couple of pulleys; one of which is fixed to the arm itself, and turns upon the same pivot, whilst the other moves upon a pivot, fixed to the lower part of the post. The chain consists alternately of single and double plates of an oblong form, and rivetted together at the ends, on the principle of a watch chain. The two pullies at the top and bottom being finished with great care, perfectly equal, and having projecting teeth, or studs, fixed in a groove in each, to engage the double or open parts of the chain, the telegraphic arm above will always follow to a hair's breadth, the movements of an index, or lever, below, attached to the lower pulley, which has a dial plate opposite to it, marked on the post, for the guidance of the operative signal man.

In the field, or on board ship, a leathern strap or a rope may be substituted in lieu of the chain, for the sake of economy; but as these expedients are incapable of the same accuracy as the former, the signal men, in working by them, must not trust to the indices, but must regulate the positions of the arms chiefly by the eye. The surface of the pulleys, when intended for a strap, must be moderately convex, those for the rope moderately concave, and both should be broader than when a chain is to be used. The leathern strap requires an extra pulley of a smaller size, for pressing in one side, and tightening it, when the telegraph is to be used. This pulley is fixed to a small lever attached to the middle of the post, and is thrown into action by a string.

When a rope is used, three turns of it are taken round each pulley, hauling it tight at the same time, after which the two ends, being previously preparpared with thimbles, or eyesplices, are brought towards each other, and made fast, by a lanniard, or smaller rope, passing through the eyes.

When the strap or rope is used, the lower pulley instead of having one short lever only, serving as an index, may have four such levers, so as to resemble a small windlass.

At the end of each arm, two light pieces of iron,

* The idea of the indicator, which was not a part of my original plan, but without which, I am now of opinion, that no telegraph is perfect, suggested itself in consequence of a remark made by my friend Captain John Tailour of the royal navy, who informed me that he had experienced the greatest inconvenience in using Sir Home Popham's ship Semaphores, from the signal men confounding the positions of the arms when seen in reverse.

meet in an angle of 45 degrees, forming an open triangle, to the vertex of which the movable lantern L is attached, by means of a pin. A cylindrical weight w must be fixed at the same time to the end of the iron counterpoise, to restore the proper equilibrium of the arms, which is, of course, deranged by the addition of the lantern. As the lanterns and weights, and in short, every addition necessary for exhibiting the nocturnal signals, are fixed at dusk, and removed by daylight, it becomes necessary, at permanent stations, that the roof of the signal house, over which the telegraph stands, shall be formed with a small flat terrace, accessible by means of a ladder or staircase.

In the intermediate stations of a permanent telegraphic line on shore, two lanterns are required to do the duty of the centre light, one on each side of the telegraphic post, because one lantern can, of course, be seen in one direction only, owing to an intervention of the post. These two, as well as the two movable lanterns, are fixed externally, at a sufficient distance from the plane of the arms, to prevent them from striking, as in Fig. 20, in which c c are the central lanterns, L L the movable lanterns, and w w the weights, added to counterpoise them.

The indicator light I may either be fixed to a separate post, as represented in Fig. 18, or it may be attached to a rod r, strengthened by a brace b, and guy ropes g g, as in Fig. 19, which is an elevation of the universal telegraph, fitted up for night signals, on a scale larger than that of the former explanatory figures. The apparatus now alluded to, having only one lantern to support, may be made extremely light. The end of the rod drops into a small open mortise at the head of the post, and has a semicircular groove on its lower surface, which is engaged by a horizontal bolt, driven through the sides of the post. A small rope fixed to the end of the rod, but omitted in Fig. 19, for the sake of clearness, is made fast to a cleat upon the post below, to prevent the rod from moving. The foot of the brace is secured to the post by a plate and stud.

This apparatus, which entirely depends upon the telegraphic post, and turns with it, may be fixed, or disengaged, in a moment, and is peculiarly adapted for ships, and for field service, in which the length of the telegraphic arm does not exceed from five to six feet. But at permanent stations on shore, where larger telegraphs would probably be used, the apparatus for supporting the indicator lamp should be a permanent fixture, to save the trouble of continually shipping and unshipping it. At such stations, if the signals were required to be made in various lines or directions, the pole for supporting the indicator lamp should be fixed to the post at bottom, so as to stand out from it obliquely, like a ship's bowsprit, with lifts, or ropes, to support it, leading to the top of the post, and a couple of guys to secure it from lateral motion. Hence one oblique spar only would be used, instead of the two pieces (namely, the rod and brace) before described. But as there may be many stations in a telegraphic establishment on shore, in which the signals require to be exhibited in one invariable line only, at all such stations, the indicator lantern should be fixed to its own separate post, which may either be placed vertically (as in Fig. 18), or obliquely, as may be considered most expedient.

Lamps for burning oil have recently been brought to such perfection, that a light of sufficient intensity, for any distance suitable for telegraphic purposes, may easily be obtained. In regard to form, if night telegraphs be adopted on shore, square lamps like those of mail coaches, but having the two glass sides opposite to each other, so as to show light in two directions only, would be the most proper. But for sea service the pattern called the "globe lamp," which has of late been generally adopted to the Royal Navy, in lieu of their former signal lanterns, appears to be decidedly the best. In this, the light is exhibited in every direction through a very strong globular glass, to which are fitted a copper top and bottom, pierced with air holes.

In respect to the dimensions proper for the parts of the Universal Telegraph, we ascertained by experiment, that the arms for the day signals should be about one foot in length per mile, in order to be distinguished by a common portable telescope of moderate power. This length is computed from the centre of motion to the end of the arm, not including the small part beyond the centre, called the head. By the above rule, a telegraphic arm, of six feet in length, may suffice for stations six miles apart; but generally speaking, in telegraphs intended for permanent stations, where the saving of the weight is less an object, it may be considered best to add a little to the dimension thus found.

The width of the arm need not exceed $\frac{2}{13}$ths of its length, and should not be less than $\frac{1}{7}$th or $\frac{1}{8}$th of the same dimension. The indicator for the day signals should be of the same width, but only $\frac{4}{5}$ths of the arm in length.

The height of the post should be such, that men, or other movable objects, passing near it, should not obscure the indicator, or arms, when the telegraph is erected on the deck of a ship, or in the field. But when placed on the roof a permanent signal-house, the projecting part of the post need not exceed the telegraphic arm, by more than $\frac{2}{3}$rds of the length of the latter.

It is desirable in all cases, that the telegraphic post should be capable of turning, so as to exhibit the arms in various directions. On board ship it must also be occasionally lowered. Hence it becomes necessary to step it upon a simple open circular joint of iron, fixed to the ship's side near the deck, and to secure it by an iron clamp, also of a circular form, attached to the rail, nearly in the same manner as the ensign staff of a man-of-war is usually fitted.

The telegraphs hitherto constructed upon this principle, are of two sizes. One having arms of $5\frac{1}{2}$ feet in length, with the lantern pivots placed $6\frac{1}{2}$ feet from the centre of motion. The other having arms of $2\frac{1}{2}$ feet in length only, with the lantern pivots three feet two inches from the centre of motion. The former are of a size suited to the largest class of men-of-war. The latter are perfectly portable, as the whole apparatus, including the night indicator, lanterns, &c. does not weigh more than 34 lbs. In clear weather, these small telegraphs make signals distinctly at the distance of three miles.

Supposing that telegraphic signals should be required on a sudden emergency, in some situation where there may not be time and means for making well finished telegraphs, in the manner that has been described, I have ascertained by experiment, that the most expeditious and satisfactory arrangement will always be to copy the regular construction, as closely as circumstances will permit. A post, with two planks for the arms, each worked merely by a couple of strings without pulleys, will constitute a day telegraph, and the addition of lanterns &c. will convert the same simple apparatus into a nocturnal telegraph. In both cases, the arms must be counterpoised by wood or iron, and also by weights, but in a ruder manner than was before described. To adopt balls or flags for day signals, or an immovable rectangular frame, with ropes and pulleys, for supporting the lanterns for night signals, which are the only other expedients that suggest themselves as a temporary arrangement, will, on trial, be found much less satisfactory than the rudest attempt at the counterpoised telegraphic arm.

It is well known, that telegraphs should generally be painted black, and that for permanent stations, they should always be erected, if possible, upon heights having no back ground.

Several telegraphic dictionaries have been composed by different authors, but of these, the one now used in the Royal Navy, which was compiled by the late Rear Admiral Sir Home Popham, appears, upon the whole, to be the most judicious. The number of words and sentences contained in it does not exceed 13,000; and yet there is seldom a deficiency of any useful word. Another author has composed a dictionary of a similar nature, containing upward of 31,000 words and phrases: and a third has composed a work containing more than 149,000 words, phrases and sentences. It may be observed, in regard to this subject, that the extension of a telegraphic dictionary beyond a certain limit is an evil, because in proportion to the number and length of the sentences contained in it, it becomes so much the more difficult to find any of them, without a vast loss of time.

Hence the advantages held out by the author of any very voluminous telegraphic dictionary, must always be in a great measure nugatory, unless the place of every phrase or sentence contained in it, could be known by intuition, which is impossible.

It is to be observed, however, that the comparative compendiousness, of Sir Home Popham's Telegraphic Dictionary, is partly owing to a practice, which he has carried to the greatest possible extent, but of which the other authors alluded to have availed themselves more sparingly, or not at all. I mean the system of classing under the same article of his dictionary, and thereby representing by one common signal, all the forms of the same verb, as well as every noun, adjective, or adverb, that happen nearly to coincide in sound, or are connected in signification. Thus the words, "agree," "agrees," "agreed," "agreeing," "agreeable," "agreeably," "agreement," "agreements," would all be denoted by one and the same signal, and comprehended under one article, in Sir Home Popham's Telegraphic Dictionary.

It is remarkable how very few ambiguities this sweeping method of classing the words of our language will be found to occasion in practice, as may be ascertained by taking any sentences, at random, out of a book, and applying Sir Home Popham's Telegraphic phraseology to them. And yet it cannot be denied, but that serious mistakes may arise at times from this system.

For example, the following phrases, "they are robbing," "they are robbed," and "they are robbers," although different in sense, would all be expressed by the same signal in Sir Home Popham's Dictionary. The phrases, "A robber has been executed," and "a robbery has been executed," would also be expressed by the same signal, and the phrases "they are going," and "they are gone," would likewise be confounded.

It is further to be remarked, that Sir Home Popham's Telegraphic Dictionary, being necessarily confined to the use of the Royal Navy, is not available for general service: and even if this restriction did not exist, it is evident, that if telegraphs were introduced into British India, or into any other of our foreign possessions, a number of military phrases and sentences, and a great number of local words and phrases would require to be introduced, which are not to be found in Sir Home Popham's book: and at the same time it might be desirable to obviate the degree of ambiguity, before mentioned in that work. This would require every verb to be expressed in two forms instead of one, and some of the nouns, adjectives, and adverbs, now classed under the same head with a verb, or with each other, to be expressed separately. For example, the word *Rob*, and others connected with it, which are at present all denoted by the same signal, might be divided into three distinct signals, in the following manner.

1st. *Rob*, *robs*, *robbing*, *robbery*, *robberies*, and to follow the same rule in regard to other verbs, including the present tense, the infinitive, and active participle, under the same head, and also any noun of the same sound, or even of kindred meaning, provided, in the latter case, that it be an action, passion, or any thing inanimate.

2d. *Robbed*, including always the past tense of the verb, and the passive participle, under one head, whether they be the same in sound or not.

3d. *Robber*, *robbers*, and to follow the same rule in regard to personal nouns, keeping them always distinct from the verbs.

It appears also advisable, that the adjective and adverb, when different in sound, although of kindred meaning, should likewise be separated from the verb. Hence it would be proper to separate the various words classed under the head *agree*, in Sir Home Popham's Telegraphic Dictionary as follows.

1st. *Agree*, *agrees*, *agreeing*, *agreement*, *agreements*.

2d. *Agreed.*
3d. *Agreeable, agreeably.*

If a select dictionary on Sir Home Popham's principle, were thus dilated, it would, in all probability, increase the contents of the work from 13,000, to about 25,000 words and sentences, and if the military and local phrases before alluded to, were likewise added, it probably might swell the amount to near 30,000. Upon the whole, I conclude, that a judicious Telegraphic Dictionary, composed on the most comprehensive plan, so as to embrace every contingency of the public service, both at home and abroad, ought not to contain so many as 40,000 articles. This inference may be considered the result of experience, inasmuch as it has been drawn from a careful comparison of the most elaborate works of that nature, that I have been able to procure.

Supposing a dictionary of this description to be composed, I would adapt it to the key of the Universal Telegraph, in the following manner.

The dictionary should be divided into five parts or classes, each containing one-fifth part of the total number of articles inserted. Thus, for example, if 30,000 articles, and 1000 blanks for unforeseen purposes, appeared necessary, let each division of the book contain 6000 articles, and 200 blanks.

Of the 28 signs, which the Universal Telegraph is capable of exhibiting, I would reject one, namely, position 4 of the day signals, in which one arm points vertically upwards, in the direction of the post prolonged; because it has been urged, that unless when viewed by a very experienced eye, it is liable to be confounded with the post, so as to be mistaken for the position called "the stop," in which neither of the arms is shown.

Of the remaining 27 signs, *one* should be used as an *Alphabetical Preparative, one* as a *Numeral Preparative,* and *five* as *Dictionary Preparatives,* each of the latter referring to its own distinct part, or class of the dictionary.

Thus there would be 7 preparatives, and 20 signs for general purposes. Each preparative would of course denote, not only the beginning of that word or sentence which is immediately to follow it, but also the end of the preceding one.

In representing the letters of the alphabet by 20 signs, the letters I and J, the letters K and Q, the letters S and Z, and the letters U and V, would be coupled together; but the letter F would require to be denoted by the two successive letters P H, and the letter X, by the two successive letters, C S or K S.

The number of signals, which may be made by three successive changes on the Telegraph, using the 20 disposable signs only, is equal to 8000, being the third power of 20; but as the beginning of each signal must be denoted by a preparative, without which the signal is imperfect, if the above 8000 articles be combined with the five dictionary preparatives before mentioned, it will be evident, that by never using more than four changes on the Telegraph, for any article of the dictionary, no less than 40,000 words and sentences may thereby be exhibited; but, as I remarked before, this number is greater than appears to be absolutely necessary, in a judicious and well composed Telegraphic Dictionary."

TELESCOPE. See Achromatic Telescope, Vol. I. p. 96, and Optics, Vol XIV. p. 594—602, and p. 769—789.

TELFAIR, county of Georgia, bounded NE. by Montgomery county; ESE. and S. by Appling: SW. by Ocmulgee river, separating it from Irwin: W. by Dooley; and NW. by Pulaski. Length from S. to N. 38 miles, mean breadth 22, and area 836 square miles. Extending in lat. from 31° 39′ to 32° 12′ N. and in long. from 5° 46′ to 6° 20 W. from W. C. The southern part of this county slopes to the southeastward giving source to many of the higher branches of Santilla river, which rise very near the margin of Ockmulgee river. The latter considerable stream forming the southeastern border of the county, thence enters and traverses it in a northeastern direction, serving as a common recipient for the confluents which drain the northern section towards Pulaski.

By the post office list of 1831, Telfair contained three post offices: Jacksonville, the county seat, Ashley's Mills and Copeland.

Jacksonville is situated in the southern part of the county, by post road 111 miles a little W. of S. from Milledgeville, N. lat. 31° 55′, long. 6° 4′ W. from W. C. Darby.

TENBY, a market and borough town of Pembrokeshire in Wales, situated at the mouth of the Bristol Channel. It consists chiefly of two streets, containing neat houses, built with stone and slated. The church, which is 140 feet long, has a large square tower, which with its spire is about 150 feet high. The harbour is commodious; the exports are coal, culm, and fish, the imports groceries, &c. This place has lately become a fashionable bathing place; and a neat theatre, assembly room, billiard table, and bowling green, cold baths, and warm and vapour baths, have been provided for the convenience of the visitors. In 1821 Tenby contained 302 houses, 373 families, 628 males, 926 females! and 1554 inhabitants.

TENEDOS, a rocky island of the Grecian Archipelago belonging to the Turks, who call it Bogtcha-Adassi. The finest wine is produced here. It is said to lose its colour but not its strength after fourteen or sixteen years. Muscadel wines, not inferior to those of Samos, are made in considerable quantities; about 600,000 okes of wine, valued at 30,000 piasters, are annually exported to Constantinople, Smyrna, and Russia. The town is situated on the slope of a hill, and the harbour is enclosed by a mole, and surrounded by a mountainous ridge. Olivier says that there are as many Turks as Greeks at Tenedos; but others reckon the Turks at 600 families and the Greeks only at 300. See Olivier's *Voyage dans L'Empire Othoman*, vol. i. chap. 24. p. 260, and Sonnini's *Travels in Greece and Turkey*, p. 505.

TENERIFFE, the name of one of the Canary Islands, situated on the west coast of Africa. In a long article on the Canary Islands in Vol. V. p. 259—265 we have already treated most of the general topics which relate to this island, and it remains only to notice some particulars which may be expected under the present article.

Teneriffe is of a triangular form, each side being about thirty-six miles in length, and chiefly consists of the Great Peak sloping down into the sea. It contains about 1540 square miles or 985,600 acres. It is divided in the middle by a ridge of mountains which have been likened to the roof a church, the peak forming the spire in its centre. Five-sixths of the island has been computed to consist of rocks, woods, and inaccessible mountains. According to Humboldt, the height of the peak is 1909 toises, or about 12,090 feet. The size of the crater on the summit is only 300 feet by 200, and its depth does not exceed 100 feet. The island is almost wholly volcanic, resting on a submarine volcano. The range of basaltic rocks which surround the island do not rise to a greater height than 500 or 600 toises, and through the midst of this formation the rocks which constitute the principal mass of the volcano, have been protruded from below. According to Dr. Daubeny, the modern lavas may be divided into two classes; 1st, Those which compose the nucleus of the mountain, and are of a trachytic character, have been forced up through the older basalt; and, 2dly, The products of the volcanic action to which this central mass furnished a vent. The last class are various. Those which have a stony aspect are low in position, and seem to have come from the flanks of the volcano, while the vitreous ones occur only near the summit at heights exceeding 8900 feet. They seem to have come from the adjoining mountain Chahorra, which is to the peak what Monte Rossi is to Mount Ætna, having been produced by a lateral eruption.

Von Buch is of opinion, that the great chimney in the peak preserves the island from those destructive eruptions which convulse some of the neighbouring ones; but though it may act as a safety valve, yet, as Dr. Daubeny observes, it is a dangerous neighbour to the towns at its base. In 1704 and 1706 lateral eruptions took place, which destroyed the harbour of Garachico, the best frequented harbour in the island. In 1798 Chahorra ejected lavas and scoriæ for three months, and as some of the fragments took from twelve to fifteen seconds to descend, they must have risen to the height of 3000 feet. Smoke constantly issues from the summit of the peak, and though it is never known to emit flames, yet sulphurous acid vapours are constantly exhaled from it, from several apertures near the lowest part of the crater. The interior of the crater is covered with yellow and white clay, and fragments of decomposed lava, under which are found beautiful octohedral crystals of sulphur.

Teneriffe is remarkable for the excellence of its climate, varying from the heat of the equinoxial regions to the colder climates of Europe. The scenery of the island is remarkable for its beauty. The date tree, the plantain, the sugar cane, the Indian fig, and the olive tree are cultivated. Wheat is reaped from the end of March to the beginning of May, and the bread fruit tree, and the cinnamon, cocoa, and coffee plants have been successfully cultivated. Above this productive region rises the region of the laurels, then the chestnut plantations, then the vast forests of pines, then the vast plain, like a sea of sand adorned with the odoriferous *retama*, and lastly the Malpays, covered with loose fragments of lava. At the extremity of the Malpays is the plain of Rambleta, with the crevices which discharge watery and heated vapours. Population about 100,000. For farther information respecting this island, see Captain Cook's *Third Voyage*, vol. i. p. 22; and *Embassy to China*, vol. i. La Perouse's *Voyage*, vol. ii. p. 226; Mr. Grey Bennet in the *Geological Transactions*, vol. ii.; Humboldt's *Personal Narrative*; Daubeny's *Description of Active and Extinct Volcanos*, p. 251; but particularly Baron Leopold Von Buch's *Physicalische Beschreibung der Canarischen Juseln*, Berlin, 1825, 1 vol. 4to, and a folio volume of Charts and Plates. See also the article Canary Isles, and the works there referred to.

TENIERS, David, a celebrated painter, and the son of David Teniers, who was also distinguished in the same profession. He was born at Antwerp in 1610, and died at Brussels in 1694. See our article Painting, Vol. XV. p. 266.

TENNANT, Smithson, a celebrated English chemist, was born at Selby in Yorkshire, on the 30th November 1761, and was the son of the Reverend Calvert Tennant, vicar of Selby. After receiving the elements of his education at Scerton, Tadcaster, and Bromley, he went to Edinburgh in 1781 to study medicine, and attend the chemical lectures of Dr. Black. In October 1782 he went to Cambridge, where he devoted himself principally to chemistry and botany. In the summer of 1784 he made a journey to Denmark and Sweden, when he paid a visit to the celebrated Scheele, with whose simple apparatus he was peculiarly pleased. In 1785 he was elected F. R. S., and in 1788 he took his degree of Bachelor of Physic. His mind was then occupied with chemical pursuits, and in 1791 he communicated to the Royal Society his discovery of a method of obtaining carbon from the carbonic acid. Being fond of travelling, he went to the continent, quitted Paris on the 9th of August, visited Gibbon at Lausanne, and after visiting Rome and Florence, he returned through Germany to Paris, which he found enveloped in all the horrors of the revolution. M. Delametherie, to whom he paid a visit, had the integrity to preserve for him some valuable property, which he found it necessary to put under his charge.

In the year 1796 Mr. Tennant took his degree of M. D., and in the same year he submitted to the Royal Society his paper on the quantity of carbonic acid in the diamond.

About this time he took a passion for farming, and for that purpose he purchased some uninclosed land in Lincolnshire. In 1797 he bought a property on the Mendip hills, near Chidder, where he built a house, in which he resided during part of every summer. In 1802 he discovered that emery was the powder of corundum, and in 1804 he discovered the two new metals of iridium and osmium, for which he received from the Royal Society the Copley medal of that year.

In May 1813 Mr. Tennant was elected Professor of Chemistry in the university of Cambridge, and in the spring of the preceding year he delivered his first and last course of lectures.

In September 1814 Mr. Tennant paid his last visit to the continent. From Lyons, Nismes, Avignon, Marseilles, and Montpellier he returned in November to Paris, where he remained till February 1815. On the 15th of February he arrived at Calais, and on the 20th he set out with Baron Bulow to embark at Boulogne. They went on board a packet on the 22d, but were driven back by adverse winds, and intended to make a second attempt in the evening. In order to spend the day they took horses to pay a visit to Bonaparte's pillar, about three miles distant, and having on their return gone to look at a small fort, on which the drawbridge over a fosse, 20 feet deep, wanted a bolt, they had no sooner got upon it than it gave way, and both of them, with their horses, were precipitated into the ditch. Baron Bulow, though stunned, escaped without any serious injury, but Mr. Tennant was found lying under his horse apparently lifeless. His skull and one of his arms were dreadfully fractured, and though when brought to the hospital he seemed to recover his senses, yet he died within an hour. His remains were interred in the public cemetery at Boulogne.

The following is a List of his Principal Papers in the Philosophical Transactions.

1. On the Decompositon of fixed Air, 1791, p. 182.
2. On the Nature of the Diamond, 1797, p. 122.
3. On the Action of Nitre upon Gold and Platina, id. p. 217.
4. On the different sorts of Lime used in Agriculture, 1799, p. 305.
5. On the Composition of Emery, 1802, p. 398.
6. On two Metals found in the Black Powder remaining after the Solution of Platina, 1804, p. 411.
7. On an easy mode of producing Potassium, 1814, p. 578.
8. On the Means of producing a double Distillation by the same heat, id. p. 587.
9. In the Geological Transactions, vol. i. 1811, he published an Analysis of a Volcanic Substance containing the Boracic acid.

For a full and minute account of the life of this eminent chemist, and accomplished individual, see Mr. Whishaw's Biographical account of him in Dr. Thomson's *Annals of Philosophy*, vol. vi. pp. 1 and 80.

TENNESSEE, river of the United States, draining the much larger portion of the state of the same name, and also a part of Kentucky, Virginia, North Carolina, Georgia, Alabama, and Mississippi. Speaking generally, Tennessee river is composed of Powell's, Clinch, Holston, French Broad, Tennessee proper, Hiwassee, Duck, and innumerable minor streams.

Powell's river, the extreme northern confluent of the basin, rises between Powell's and Cumberland mountains in Russell county, Virginia, flowing thence southwestward over Lee county of Virginia, and Claiborne and Campbell counties, Tennessee; joins Clinch river at Grantsborough, after a comparative course of one hundred miles. Powell's river draws its sources on the western side of the valley, from Cumberland mountain opposite to those of Cumberland river.

Clinch river has its remote sources in Tazewell county, Virginia, interlocking sources with those of Powell's, Sandy, Blue Stone, and North Holston rivers, and flowing thence southwestwardly over Russell and Scott counties, Virginia, enters Tennessee, wherein, after separating Hawkins, Granger, and Anderson from Claiborne, it enters Campbell and receives Powell's river as noticed above. Below their junction, the united water continues southwestwardly over Anderson and Roane counties to their union with the Tennessee at Kingston. The entire comparative course of the Clinch is 190 miles: 150 above and 40 below the mouth of Powell's river.

Directly opposite Kingston, Clinch receives from the northwestward, Emery's river, a comparatively small but important stream from Morgan, White, and Bledsoe counties. Including the minor valley of the latter, the entire valley of Clinch a little exceeds two hundred miles in length; but with all its constituents the valley is very narrow, as it in no place exceeds thirty, and scarcely admits an allowance of twenty miles mean width: area 4000 square miles.

Holston river rises in Tazewell and Wythe counties, Virginia, by two branches called relatively North and South Holston. North Holston, the most remote northeastern source of Tennessee, rises between Walker's and Clinch mountains, and flowing thence southwestwardly over Washington and Scott counties, Virginia, turns abruptly southward into Tennessee, and joins the South Branch at Kingsport, between Hawkins and Sullivan counties. The South Fork of Holston, issuing from Wythe, traverses Washington county, Virginia, and Sullivan county, Tennessee, unites with the North Fork as stated. The South Holston is augmented in Sullivan by a considerable branch of the Watauga. The latter rises in Ashe county, North Carolina, by several branches which pierce the Bald or Iron mountain in a northwestern direction. These streams unite in Carter county, and join the South Holston in Sullivan.

Below the union of its two main branches, the now navigable Holston maintains a southwestern course over Hawkins, Granger, and Knox counties to its junction with French Broad river above Knoxville. Still continuing the original course, over the lower part of Knox and between Blount and Roane, receives Tennessee proper from the southeastward, and turning thence to the northwest joins Holston at Kingston.

French Broad is a stream of considerable magnitude, deriving its highest sources from the western spurs of Blue Ridge, near the border of Greenville district, South Carolina, and opposite to the sources of Saluda and Savannah rivers. Pursuing thence a northern course over Buncombe county, it inflects to northwestward, traverses the Bald mountain, enters Tennessee, where, after separating Greene from Cocke county, it receives its main northern branch the Nolachucky on the border of Jefferson county. The Nolachucky issues also from the Blue Ridge, opposite to the sources of Catawba river, and flowing thence northwestward, drains the northern part of Buncombe county, pierces the Bald or Iron mountain, enters Tennessee, and traversing Washington and Greene counties, falls into French Broad between Cocke and Jefferson counties. Below the union of the two confluent branches, the general course of French Broad is to the westward, but with a sweeping curve to the south to the mouth above Knoxville. The entire length of the French Broad by comparative courses is about 140 miles: 100 above, and 40 below the mouth of the Nolachucky.

The valley of French Broad, including that of Nolachucky, occupies a triangle of 90 miles base, with 70 miles perpendicular; traversed nearly centrically by N. Lat. 36° and Long. 6° W. from Washington City.

Tennessee proper, though a minor constituent even when compared with the French Broad, has by the course of original discovery given a generic name to the valley. The extreme source of Tennessee is in Rabun county, Georgia. Issuing thence, from the northern spurs of Blue Ridge, by the name of Estato creek, it enters North Carolina between Haywood and Macon counties, and gradually winding from a northern to a northwestern course, receiving tributary creeks from both counties, but particularly the Tuckaseege from Haywood, traverses the gap between the Unika and Iron mountains, enters Tennessee, and, separating Monroe from Blount, falls into Holston opposite the southern part of Roane county. The entire comparative length of Tennessee is about 85 miles; of which 5 are in Georgia, and 40 in each of the other two states.

Hiwassee is the lowest stream deserving the name of a river which enters Tennessee from the left. This confluent has its extreme sources in Rabun county, Georgia, but yet small creeks, they enter Macon county of North Carolina, where they unite, and assuming a course of northwest by west, traverse the Unika or Iron mountain, enter Tennessee, and separating the Amoi district of the Cherokee territory from M'Minn county, falls into the main volume of Tennessee river, about 50 miles comparative course below Kingston.

The distinctive name of Tennessee is applied to the volume below the junction of Holston and French Broad. Already a large stream, it is, however, greatly augmented at Kingston by the influx of the Clinch. The general course of Clinch is maintained below Kingston, and continuing southwestward, by comparative courses, 160 miles, receiving the Hiwassee from the left and the Sequatchee from the right, Tennessee abruptly turns to northwest by west, and piercing Cumberland mountain, merges into its lower valley, after a comparative course, following either the Clinch or Holston, of 350, or by the French Broad, 300 miles. Including all the minor valleys, Upper Tennessee drains an elongated ellipse of 350 miles larger axis, and with a shorter axis of 120 miles. The larger axis extends in a direction a little E. of N. from the great bend at the passage through Cumberland mountain to the sources of Holston; and the shorter axis stretching from the sources of French Broad in the Blue Ridge to those of the extreme northwestern branches of Powell's river in Cumberland mountain. The area of the whole elliptical valley is about 24,000 square miles.

It would be very satisfactory to have been able to give the relative height of the extremes of this interesting physical section, but this result can be only stated by approximation. Without estimating the mountain ridges, the mean arable surface of Tazewell county of Virginia, has been estimated at 1200 feet; we may therefore assume at least 1500 feet as the relative elevation of the fountains of

Tennessee. The surface of the water passing through Cumberland mountain is at the utmost not more than 750 feet elevated above the Gulf of Mexico; but with that allowance, Upper Tennessee valley will have, on a plain of 350 miles, 750 feet fall, or something above two feet per mile. The real descent is probably rather greater than shown by this estimate.

Descending from the extreme fountains in Virginia, the valley widens as the mountains recede from each other, and again contract as the same chains again reapproach gradually towards each other at the northwestern angle of Georgia, and the northeastern of Alabama. At the latter point below the influx of Sequatchee, well known under the name of Nickajack, all the large confluents have united, and the Blue Ridge and Cumberland mountains have inclined to within less than forty miles of each other. Below Nickajack, in a distance of 60 miles, the valley becomes more and more confined in width, and without receiving a single creek of twenty miles course, the large volume pours down its mountain channel, the two chains still approaching each other until their actual contact forces the stream through a gorge of Cumberland.

If we suppose a traveller arrived on the bank of Tennessee, immediately below its passage through Cumberland mountain, and who had no knowledge of the geography of the higher valley, he would be far from suspecting himself on a stream draining 24,000 square miles, and formed by such constituents as Clinch, Holston, and French Broad. If such an observer had previously and completely explored the lower valley, he would in the supposed situation regard the main Tennessee as a mere branch.

The importance of this physical section has been fully developed, and may be safely compared with any other of equal extent on the earth in richness, grandeur, and variety of scenery; in fertility of soil, and salubrity of air, and purity of water.

Politically, Upper Tennessee valley contains, in Virginia, part of Russell, Tazewell, and Wythe counties, and all Washington, Scott, and Lee counties: in North Carolina part of Ashe, and all Buncombe and Macon, with the far greater part of Haywood county: in Georgia, with a section of the Cherokee territory, about one half of Rabun county: in Tennessee, with a section of the Cherokee territory, all the counties of Hamilton, Marion, M'Minn, Monroe, Rhea, Bledsoe, Roane, Knox, Sevier, Cooke, Greene, Jefferson, Granger, Hawkins, Washington, Carter, Sullivan, and Claiborne counties, with part of Campbell and Anderson counties; and in Alabama, with a triangular section of the Cherokee territory on the left, and about one half of Jackson county on the right bank of Tennessee river.

Advancing from S. to N. Tennessee is the first and far most important of a series of rivers which have corresponding curves. It is difficult to make the force of this observation clear to the mind by verbal description, but a single view on a map of the United States, will exhibit Tennessee, Cumberland, Greene, Salt, Kentucky, and Licking rivers flowing in channels which sweep in semicircles round each other; and, in fact, that part of Ohio river above the influx of Great Miami conforms to this remarkable system.

The volume of Tennessee has gained its extreme southern curve where it passes Cumberland mountain, and a small creek which enters above the pass is at its source the most southern fountain of the valley. It is here, at the head of Black Warrior river, that the two mountain chains of Cumberland and Blue Ridge merge into each other; and along the northern sources of Mobile the Appalachian system changes its distinctive character, and the confused masses of hills follow each other westwardly towards the Mississippi river over the states of Alabama and Mississippi. Below the Cumberland pass, the deflection of the river exceeds that of the mountains. The former flows NW. by W. 150 miles by comparative course, traverses under the name of Muscle Shoals, a minor chain, and at the northwestern angle of Alabama, and the northeastern of the Mississippi state, re-enters Tennessee, and curves to a northern course; which latter direction it maintains across a little more than two degrees of latitude to its entrance into Ohio, after an entire comparative course of 680 miles.

In a comparative channel exceeding 300 miles, Lower Tennessee does not receive from the left a single confluent above the size of a large creek; but on the opposite side, it is augmented in descending, by Pigeon-Rock, Elk, and Duck rivers, with numerous creeks.

Elk river rises in Franklin county, state of Tennessee, and in the northwestern spurs of Cumberland mountain; and flowing thence something W. of SW. over Franklin, Lincoln, and Giles counties, Tennessee, enters Alabama, where after passing obliquely over Limestone county, falls into Tennessee river in the SE. angle of Lauderdale county, and below the head of the Muscle Shoals, after a comparative course of upwards of 100 miles. It may be remarked, that the extreme sources of Elk river are within little more than 20 miles from the main channel of Tennessee, at a place called "The Suck," 25 miles above Nickajack, and following the latter stream 140 miles above their junction.

Duck river heads in the same region with the sources of Elk, but the former assumes a course a little W. of NW. and very nearly parallel to the opposing courses of Tennessee and Cumberland rivers. Rising in Warren county, Duck river traverses Bedford, Maury, Hickman, the northeastern angle of Perry, and falls into Tennessee in the southern side of Humphries county, after a comparative course of 125 miles entirely in Tennessee.

Below the influx of Duck, the channel of Tennessee rapidly approaches that of Cumberland on the right, whilst on the left the sources of Obion river flowing into the Mississippi, rise within 12 or 15 miles from the bank of Tennessee, confining upwards of 80 miles of the lower part of the valley to a width in no place 45 miles, and not averaging above ten or twelve miles mean breadth.

Taken as a whole, Lower Tennessee valley approaches the form of a trapezium: the western side, from the sources of Bear Creek in Alabama to the influx of Tennessee into Ohio, two hundred miles; and an equal distance along the northeastern side from the Ohio to Cumberland mountains at the source of Elk river. The southeastern and southern sides are also very nearly equal, or one hundred miles each; the whole figure comprising very nearly 17,600 square miles; of which the far largest proportion spreads above the mouth of Duck river.

If we except a small extent below the entrance of Tennessee river into the state of Kentucky, no part of Lower Tennessee valley is a tame level, though much less broken than the higher valley above Cumberland mountains. The soil of Lower Tennessee is also generally superior to that of the upper part. Limestone abounds more below the mountain chains.

Politically, Lower Tennessee valley comprises in Alabama, south of Tennessee river, a small section of Cherokee territory, on the east; the counties of Morgan, Lawrence, and Franklin, with a section of Chickasaw territory on the west; and north of Tennessee river all the counties of Lauderdale, Limestone, and Madison, with the western and larger portion of Jackson: in the state of Tennessee this section embraces all the counties of Franklin, Lincoln, Bedford, Giles, Maury, Hickman, Lawrence, Wayne, Hardin, Perry, and Humphries, with part of Stewart, Henry, Carroll, Henderson, M'Nair, Williamson, and Dickson: in Kentucky, part of Calloway and M'Cracken west, and of Livingston, Caldwell and Trigg, east of Tennessee river.

The entire valley of Tennessee comprises an extent of 41,600 square miles. If the valley of Tennessee is compared with the whole valley of Ohio, the former spreads over very nearly a fifth part of the latter, and gives to Tennessee the first rank amongst the confluent streams of the general recipient.

Amongst the peculiar features of Tennessee, the most remarkable is, that rising as far north as Lat. 37° 10', and curving thence southwardly to Lat. 34° 23', the channel again recurves back to its original latitude, and falls into Ohio river almost exactly due W. from the primitive fountains in Tazewell county; thus embosoming nearly the whole large valley of Cumberland, and part of that of Green river.

Geographically, Tennessee valley lies between N. lat. 34° 10' and 37° 10, and in long. between 4° 15' and 11° 40' W. from W. C. It is the first and largest, advancing from south to north, of those streams which gush from the elevated vales of the Appalachian system, and which flow westward into the great basin of the Mississippi.

In relative height above the ocean, if the mountains are included, there is a difference of from 1700 to 2000 feet between the extremes of Tennessee valley. The arable surface of Tazewell and Wythe counties in Virginia we saw estimated at 1200 feet; that of high water at the confluence of Tennessee and Ohio but little, if any, exceeds 300 feet, giving a difference of 900 feet to the cultivated surface. This comparison may be regarded as a nearly just mean, and is fully equal to two degrees of latitude, and in part accounts for the great difference of climate on the same curve of latitude near the Ohio and on the sources of Clinch and Holston rivers.

The current of every branch of Tennessee is very rapid, shoals are common, but direct falls rare. Of shoals, the most remarkable are those which have become so well known under the name Muscle Shoals, between the counties of Lauderdale and Lawrence in Alabama. These shoals are, at all seasons, difficult to navigate, though from the infrequency of accident, must be far less dangerous than usually represented. With all its impediments from shoals and rapid descent of the general plain, Tennessee valley is navigated downwards from very near the sources of most of its streams.

TENNESSEE, one of the United States of America, bounded by North Carolina E.; Georgia SE.; Alabama S.; state of Mississippi SW.; river Mississippi separating it from Arkansas W. and state of Missouri NW.; state of Kentucky N., and Virginia N. E.

If we commence the outline of this state on the southern boundary of Virginia, it will thence have a boundary:

	Miles.
In common with North Carolina, along the main spine of the Appalachian mountains, to the northwestern angle of Macon county,	168
Due S. along the western boundary of Macon county to the northern boundary of Georgia,	20
Due W. along the northern boundary of Georgia, and N. Lat 35° to the northeastern angle of Alabama,	90
Continuing the last noted line along the northern boundary of Alabama, to Tennessee river, and to the northeastern angle of the state of Mississippi,	145
Still continuing due W. along the northern boundary of the state of Mississippi, to the left bank of the Mississippi river,	110
Thence up the latter stream by comparative courses, opposite the territory of Arkansas and the southeastern angle of the state of Missouri,	100
Continuing up the Mississippi river to the northwestern angle of Tennessee, and the southwestern of Kentucky,	70
Thence due E. along the southern boundary of Kentucky, to the Tennessee river,	80
Thence up Tennessee river,	12
Thence by a line a little S. of E. along the southern boundary of Kentucky to Cumberland mountains and to the southwest angle of Virginia,	268
Along the southern boundary of Virginia to place of beginning,	108
Having an entire outline of	1171

Extending in Lat. from 35° to 36° 37' N.; and in Long. from 4° 39' to 13° 14' W. from W. C.

The longest line that can be drawn in one direction on any state of the United States, is a diagonal over Tennessee from the northeastern to the southwestern angle. This line is by actual calculation within a trifling fraction of 500 miles, and declines from the meridians by an angle of 77 degrees. The mean length of this state is about 400 miles, and the mean width being 114 the area is 45,600 miles; equal to 29,184,000 statute acres. This area exceeds the extent usually given to Tennessee, but following the most recent, and we may suppose, most accurate delineation on Tanner's Map of the United States, the estimate here given is very near the real superficies of this state.

By reference to our notice of Tennessee river valley, it will be obvious how greatly the physiognomy of the state is modified by its rivers. Dividing Tennessee into physical sections, and taking the mountains as lines of demarcation, it presents two unequal parts; one the smallest above, and another, the second and largest, below the Cumberland mountain chain.

The higher, and in point of extent relatively, the inferior section, is entirely comprised in the upper valley of Tennessee, and is in length diagonally from southwest to northeast, 280 miles, with a mean breadth of 57 miles; area 15,960 square miles, or very near the one-third of the state. This comparatively elevated and diversified region is amongst the most delightful portions of the American continent. Under the head of Tennessee river we have already remarked, that higher Tennessee had a winter climate modified by its superior elevation over the Atlantic coast and banks of the Mississippi river, or similar latitudes On lower Tennessee, cotton is a staple production, whilst the climate of the upper section is more congenial to cereal gramina and the grasses. The declivity of upper Tennessee is to the southwestward, and by a very rapid general descent. The declination of lower Tennessee is more gentle, and to the west of northwest.

Lower or western Tennessee is subdivided by its rivers into two sections. That part comprised in the valley of Tennessee river has been already noticed under the head of that stream; but to the northward of Tennessee valley, the state embraces a large and very important tract in that of Cumberland river. The latter tract is about 250 miles in length along the line between the states of Tennessee and Kentucky, with a mean breadth of 40 miles, and contains 10,000 square miles. That part of the state comprised in Lower Tennessee valley is about 170 miles long, with a mean breadth of 70, embracing an area of 11,900 square miles.

Including both upper and middle Tennessee, or the sections contained in the valleys of Tennessee and Cumberland rivers, we have an aggregate area of 37,860 square miles, of which 21,900 are comprised in the middle region.

The general declivity of lower or middle Tennessee is westward towards Tennessee river, as that great stream flows here in a channel near the base of the central plain. But passing, not only the channel, but the entire valley of Tennessee, we find a slope falling westward towards the Mississippi river, and drained by Obion, Forked Deer, Big Hatche and Wolf rivers. These small rivers have corresponding curves, first flowing northwestwardly, thence west, and finally southwest into their great recipient the Mississippi. This western inclined plane may be considered, both physically and politically, as West Tennessee, and comprises 7,740 square miles.

In its natural state the whole surface now included in Tennessee, was covered with a dense forest. The great features along its very elongated declivity of five hundred miles, are varied and strongly contrasted. East Tennessee, mountainous or very hilly, with excellent river soil, presents a most seductive picture to the eye. Middle, or central Tennessee, less bold in its physiognomy, but with a much larger proportion of productive soil, is followed by the western section. The features of nature, from the Cumberland chain, imperceptibly softening, until finally sunk into the annually inundated banks of the Mississippi. The state has, on all its parts, a sufficiency of soil to admit a dense and not very unequally distributed population. Agreeable to the return of the recent census of 1830, middle and western Tennessee, containing a surface of 29,640 square miles, had an aggregate population of 488,448. In 1820, the same surface had only 287,501 inhabitants, having increased almost 70 per cent in ten years.

The mean density, however, in 1830, was still only about 16 to the square mile, on a soil and surface where ten times the number would be far from reaching the natural capacity of support.

For the political subdivisions, or counties of Tennessee, with their respective population in 1830, see Art. U. S., Section TENNESSEE.

History.—The territory now forming the state of Tennessee, was, with a small exception on the northern border, included in the second charter of North Carolina, granted to Clarendon and others by Charles II. in 1664, but no white settlement was made so far westward until 1754, when a few families fixed themselves on Cumberland river, but were soon after driven away by the savages. The first permanent settlement in Tennessee was made by the founding of Fort Loudon in 1757. According to Flint's Geography and History of the Western States, Fort Loudon stood on Little Tennessee, one mile above the mouth of Tellico. This place is now included in Blount county. On Pownall's map, founded on that of Evans, the latter published in 1755, it is noted, that the farthest settlements of Virginia westward, in 1755, were on the heads of Bluestone, branch of New river or Great Kanawha, and on the heads of Clinch and Holston. Tennessee was then one wide wilderness. As noticed under the Article Tennessee river, the course of original settlement was from North Carolina into the valley of Tennessee proper, above its junction with Holston. Fort Loudon was then the cradle of Tennessee. This fortress was attacked in 1760 by the Indians, taken, and upwards of two hundred men, women and children massacred.

In 1761, the important campaign under Col. Grant broke the power of the savages. A treaty was made, which encouraged emigrants, and about

1765, settlements began to be made on Holston which gradually increased. Though harassed by savage warfare, the hardy frontier men penetrated deeper and deeper into the forest, and at the opening of the revolutionary war, were sufficiently strong to meet their savage enemies. Col. John Sevier was the hero of Tennessee at that period. In June 1776, the inhabitants, aided by a few Virginians, defeated the Indians. Hostilities continued nevertheless, between the parties, through the revolutionary war.

When in 1776, the first republican constitution of North Carolina went into operation, deputies from the western counties, now in Tennessee, appeared in the first state assembly.

The early settlements were entirely above the chain of Cumberland, and a party of hunters in 1779, found the country on Cumberland river in the fine region where Nashville now stands, a wilderness. Merged in the great border of frontier from Canada to Florida, the inhabitants on Tennessee river, first gained political importance, Oct. 7th, 1780, by their share in defeating the British and tories at King's mountain. In 1782, courts of justice were established and in the ensuing year a land office; and finally Tennessee obtained individual existence in 1784, by a cession of its territory to the United States. This act was legally repealed, but the historical effect remained in force. The people unwilling to remain under North Carolina, formed an independent government under the name of the state of Frankland. Anarchy succeeded. North Carolina claimed jurisdiction, and was resisted by the constituted authorities of Frankland. Power prevailed in the struggle, and the state of Frankland disappeared. The contest was marked by many acts of violence which were not terminated until after 1790, when North Carolina definitively ceded the territory to the United States. By a law of Congress, passed May 1790, the country of Tennessee was made a territory by the name of "*The Territory South of the river Ohio.*" The first printing press was established at Hagersville, Nov. 1791, and on the 5th of that month, was issued the Knoxville Gazette, the first newspaper of Tennessee.

The country advanced in population, and on the first of June 1796, Tennessee was formally admitted into the Union, as a state of the confederacy. Since her introduction into the family of republics, the progress of Tennessee in power and wealth, has been constant and peaceable. The late war between the United States and Great Britain, exhibited the troops of Tennessee as the worthy representatives of the heroes at the slopes of King's Mountain.

Government.—The legislative power is vested in a general assembly composed of two branches, denominated the senate and house of representatives, elected biennially. No person is eligible to a seat in either house, unless he shall have resided three years in the state and one year in the county, immediately preceding the election, and shall possess in his own right in the county which he represents not less than 200 acres of land.

The executive power is vested in a governor, chosen by citizens qualified to vote for members of the general assembly. The governor must be at least thirty-five years of age and possess a freehold estate of 500 acres of land, and have been a citizen or inhabitant of the state four years next before his election, unless he shall have been absent on the public business of the state or of the United States. His term of office is two years and until his successor shall be elected and qualified, but he is not eligible more than six in any term of eight years.

The judicial power is vested "in such superior and inferior courts of law and equity as the legislature shall from time to time direct and establish."

The general assembly by joint ballot of both houses, appoint the judges of the several courts, also an attorney or attorneys for the state, who hold their respective offices during good behaviour.

Article 3d, section 1st, of the constitution, thus defines the right of suffrage, "every freeman of the age of twenty-one years and upwards, possessing a freehold in the county wherein he may vote and being an inhabitant of this state, and every freeman, being an inhabitant of any one county in the state, six months immediately preceding the day of election, shall be entitled to vote for members of the general assembly for the county in which he shall reside."

Education.—For the advancement of classical education, the principal seminaries in Tennessee, are the Nashville University, at Nashville; East Tennessee College, at Knoxville; Greenville College, at Greenville, Green county; and the Western Theological Seminary, at Marysville, the seat of justice of Blount county.

Manufactures.—The principal manufactures are iron, cotton, hemp, cordage, paper, gunpowder, and maple sugar. In East Tennessee, there are many iron manufactories. In 1810, the value of the manufactories was reckoned 3,708,000 dollars. In 1813, 700 workmen were employed in manufacturing saltpetre in Bigbone cove, to the amount of 500 lb. daily. In 1820, the manufacturing population was 7860.

Tennessee carries on a considerable trade to the other states. The chief exports are cotton and tobacco, hemp, flax, horses, live cattle, Indian corn, saltpetre, ginseng, and iron. The imports are chiefly dry goods and groceries, brought in wagons to East Tennessee from Philadelphia and Baltimore, and from Pittsburg and New Orleans by the rivers. The number of persons engaged in commerce in 1820, was 882.

Chief Towns.—The principal towns are Murfreesborough, Nashville, and Knoxville. Nashville, the seat of government, about thirty-two miles N.W. of Murfreesborough, is agreeably situated on Cumberland river, which is navigated to the town by steam boats and vessels of 130 and 140 tons. Knoxville, the capital of East Tennessee, is situated on Holston river. The State bank is established here, with a branch at Nashville. The capital is 400,000 dollars. There is also a branch of the United States bank recently established at Nashville, with a capital of 1,000,000 dollars.

TENSAW, river of Louisiana, has its extreme source in Grand Lake, and in the southeastern angle of Chicot county, Arkansas. Grand lake is evidently a remains of an ancient bend of the Mississippi, and Tensaw river is as evidently a former outlet of that great stream, and consequently has a similar origin with Atchabalaya, Iberville, Plaquemine, and La Fourche. Issuing therefore from Grand lake, the Tensaw immediately below its efflux enters Louisiana, in the parish of Ouachita, and flowing thence a little S. of SW. and nearly parallel to the general course of the Mississippi, by comparative courses about 110 miles to its junction with Ouachita to form Black river. The Tensaw is the drain of the inundated tract, west from the Mississippi river and in the parishes of Ouachita and Concordia.

TEQUENDAMA, Cataract in the river Bogata, about 8 or 10 English miles to the N. W. of the city of Bogata, department of Cundinamarca, Colombia, South America. This very remarkable series of falls forming one vast cataract, occurs in a mountain stream issuing from the Paramo del Chigasa, and falling into the Rio de la Magdalena. A plan of Tequendama and admeasurement of its descent in feet, was sent, in 1790, to the king of Spain, by the Col. Commandant Don Domingo Esquiaqui. The results reduced to English feet were

First Fall,	$32\frac{1}{2}$
Second Fall,	$253\frac{1}{2}$
Third Fall,	$581\frac{3}{4}$
Entire Fall,	$867\frac{3}{4}$

Compared with similar phenomena, in height, Tequendama is only exceeded by the Stanblach near Lauterbrun in the Canton of Berne in Switzerland, which falls 900 feet; or, in quantity of water by Niagara, falling direct 162 feet. But combining actual elevation with comparative body of water, the Tequendama has no equal amongst the cataracts known to exist on this planet.

It is not a very unfrequent error to consider Niagara as having the greatest direct fall of any known cataract. The entire fall from the surface of Erie to Ontario, is only 333 feet. Catskill fall in New York, has a descent of 300 feet, and those of Montmorenci, near Quebec, of 246 feet. DARBY.

TERENCE, PUBLIUS TERENTIUS, a Roman writer of Comedies, was born at Carthage in B. C. 197. He came to Rome as the slave of one Terentius, whose name he took. His first comedy, the Andrio, was exhibited B. C. 166. His Eunuch was acted twice on the same day, and brought him 8000 sesterces, or about L.64. Six of his comedies are extant. When he had presented them to the public, he left Rome for Greece, and never returned. Some affirm that he perished by shipwreck. Among the best editions of this author, are those of Bentley, Cantab. 4to. 1726, Zeunier, Lips. 8vo. 1774, and Brunckius, Basil, 4to. 1779. See our Article DRAMA, Vol. VII. p. 705.

TERNATE, one of the Molucca isles, is about 21 miles in circuit, having a lofty volcanic mountain in its centre, which sometimes emits smoke and flame. It suffered greatly from earthquakes in August 1770. East long. 127° 10′, N. lat. 8° 50′. See MOLUCCAS, Vol. XIII. p. 693.

TERRA DEL FUEGO. See FUEGO, Vol. IX. p. 492.

TERTULLIAN, QUINTUS SEPTIMIUS FLORENS, the most ancient of the Latin fathers, was born at Carthage about the middle of the second, and died a little before the middle of the third century. He is the author of many works, of which his *Apology for the Christians* is the principal one. Its object is to show the injustice of the persecutions to which they were exposed, and the excellence of the Christian religion. The best editions of his whole works are those of Rigaltius, Paris, Feb. 1641; and of Semler, Hal. Magd. 6 vols. 1770—76.

TETBURY, a market town of England in Gloucestershire. It is pleasantly situated on an eminence near the source of the Avon, and consists of four well built streets with a large market house at their place of divergence. The church is handsome, consisting of an ancient tower with a spire and a modern body, which cost L.5000. There is also here a free school, an alms house, and a manufacture of woollen cloths. Races are held near the town. To the north of the town there is a petrifying spring. The population of the parish in 1821, was 527 houses, 580 families, and 2734 inhabitants.

TETUAN, See MOROCCO, Vol. XIII. p. 682.

TEWKESBURY, a market and borough town of England in Gloucestershire, is situated in the vale of Evesham, on the east bank of the Avon. The town consists of three spacious streets composed chiefly of brick houses. The high street is long, spacious, and elegant. The houses which are good, are chiefly modern, though some specimens of the ancient style remain. The principal building is the abbey church, a fine specimen of early Norman architecture, which contains many rich monuments erected to its patrons, or to the nobility who fell at the battle of Tewkesbury. It is 300 feet long, and the tower is 152 feet high. The other religious buildings are meeting houses for Independents, Quakers, Baptists, and Methodists. The town hall is a handsome edifice, the ground floor being appropriated for the quarter sessions, and the principal story for a banqueting or ball-room. The new jail is a neat building, and there is an elegant school house on Dr. Bell's plan. The house of industry is spacious. There are also here a free grammar school, an endowed charity school, several almshouses, a dispensary, a lying-in-establishment, and schools on the plans of Bell and Lancaster. The principal manufacture here is that of stocking frame work knitting, chiefly in cotton. Nails are likewise made, and a considerable malting business is carried on. There are several commodious bridges near the town, and that over the Avon is of great length. The town sends two members to parliament, who are elected by about 500 votes. The population of the borough in 1821 was 1044 houses, 1172 families, 865 families in trade, 122 ditto in agriculture, total population, 4962. An account of the battle of Tewkesbury will be found in our article ENGLAND, Vol. VIII. p. 467. See the *Beauties of England and Wales*, Vol. V. p. 683, &c.

TEXAS.

TEXAS. Previously to the revolution which secured the independence of Mexico, Texas formed one of the internal provinces (Provincias Internas) of New-Spain, which, with the adjoining province of Coahuila, constituted an important part of the intendancy of San Luis Potosi. This sub-division of New-Spain, then so called, comprehended the provinces of New-Santander, San Luis Potosi, New-Leon, Coahuila, and a large portion of New-Mexico. Thus stood the territorial limits of this part of Mexico when the government of that republic was organized. In 1822, this vast territory was, by a special act of the Mexican congress, divided into three distinct states, whose governments, respectively, were modelled in strict conformity to the federal constitution, then recently adopted. The states thus erected, were severally denominated, New-Leon, San Luis Potosi, and the Interior of the East. The two former retained their provincial names and limits unchanged,—the other embraced the provinces of New-Santander, Coahuila, and Texas. The great extent of the latter state, and the consequent difficulty of administering its internal affairs, soon rendered fresh changes necessary, and in 1824, the province of New-Santander was detached from this unwieldy member of the confederacy, and formed into an independent state, under the title of "Tamaulipas." The remaining provinces were at the same time united and erected into the state of "Coahuila and Texas." By the law which fixed the limits of these states, a considerable portion of Coahuila was annexed to the territory of Santa Fe, or New-Mexico.

No important change in the civil divisions of these states has since been made.

Having thus briefly traced the boundaries of this part of Mexico, as they existed at different periods, we shall proceed to define the limits of Texas proper, as they are at present known and recognised, by the Mexican government on the one hand, and that of the United States on the other.

Texas, the easternmost province of the state of Coahuila and Texas, is situated between the 27° and 35° of north latitude, and 16° and 26° of west longitude from Washington city, or 93° and 103° west of Greenwich. Bounded on the north by the United States territory of Arkansas and district of Ozark, from which it is separated by Red river; east by the state of Louisiana; south by the Gulf of Mexico and state of Tamaulipas, and west by the state of Chihuahua, the province of Coahuila, and territory of Santa Fe, formerly New-Mexico. The general outline of Texas may be thus described—length on the gulf coast, from the mouth of the Sabine to that of the Nueces, the south west limit of the province, 260 miles—up the Nueces to its source, 350—along the ridge which separates the waters of Rio Bravo from those of the Brazos, Colorado, &c. to its termination on Red river, 430—down Red river to a point due north of the western boundary of Louisiana, 560—thence due south, and along with that boundary to the Sabine, where it is intersected by the 32° of north latitude, 60—and down the Sabine to the place of beginning, 220 miles, making an entire outline of 1620 miles. The area of Texas, within the above described limits, as deduced from careful computation by reticulated lines, is 179,200 square miles, and is equal in extent to the states of Louisiana, Mississippi, Alabama, and South Carolina.

If we regard Texas as extending to the Rio Bravo, as erroneously represented by some of the old maps, its entire area would be increased to about 330,000 square miles, and would present an aggregate superficies, equal to the states of Georgia, Tennessee, and North Carolina, in addition to those above enumerated. Such an extension, however, is not warranted by any act either of the government of Mexico or that of the mother country. It would embrace two-thirds of Coahuila, which forms a distinct province of the state; nearly one-half of Tamaulipas; about one-third of the state of Chihuahua, and a large portion of the territory of Santa Fe.

Gulf Coast, Bays, &c.—Commencing at the outlet of Sabine lake, the coast of Texas assumes a direction towards the southwest, which it follows to Galveston bay, a distance of fifty miles. Galveston bay is formed by Point Bolivar, Pelican and Galveston islands, and is the most extensive opening in this part of the Gulf of Mexico. It affords a good harbour and safe entrance, having always twelve, and sometimes fifteen feet water on the bars. This bay extends about 35 miles in a northwest direction from Galveston island, by which and Point Bolivar it is completely land-locked; its mean breadth is fifteen miles, and covers an area of 525 square miles. From the eastern point of Galveston island, the coast extends in the same direction towards the southwest, for 30 miles, to the west pass or entrance of Galveston island sound. From the west pass the same course is maintained for nearly 85 miles, without any material variation, to Passo Cavallo, or entrance of Matagorda bay. About 20 miles southwest of Galveston inlet, the great river Brazos enters the Gulf of Mexico, and at a further distance of 12 miles, that of St. Bernard discharges itself into the same gulf. Matagorda bay is nearly equal in dimensions to Galveston bay, but is of an irregular form. The observations respecting the latter apply with equal force to Matagorda bay.

From Passo Cavallo, the coast still continues its direction towards the southwest, to Aransaso inlet, a distance of 60 miles. Midway between Passo Cavallo and Aransaso inlet, the Bay of Espiritu Santo approaches within two miles of the gulf, with which it often communicates during the prevalence of high easterly winds. This bay, with Aransaso, and a small bayou, which connects the former with Matagorda bay, detach a considerable portion of the soil from the main land, and form the Island of Espiritu Santo. The bay of the same name lies nearly parallel with the coast, and is distinguished only as the recipient of the rivers San Antonio and Guadalupe, which unite ten miles above the bay.

Due west of Espiritu Santo bay, and northwest of the island, lies the Bay of Aransaso, extending westward 30 miles, and of the mean breadth of about five miles. At Aransaso inlet the coast turns, and pursues a course due south 25 miles, to Copano, the outlet of Nueces river, and termination on the southwest, of the coast of Texas. About 30 miles from its outlet, the Nueces expands into a spacious bay, which is joined by another from the north, of nearly equal extent, and similar in form; the latter is called Papelote bay, from a small stream of that name which enters its western margin. Texas has a front on the Gulf of Mexico, of two hundred and sixty miles in extent, which, like most other parts of the gulf, is almost entirely destitute of good harbours. Its bays, with some exceptions, are generally shallow, and their navigation much impeded by saudbars and shoals, which are suddenly formed and as suddenly disappear. The bars at the river mouths are equally variable, and seldom afford more than from four to twelve feet water.

Rivers and Lakes.—*Red River*, which forms the entire northern boundary of the province, as well as that between Mexico and the United States, agreeably to the treaty of 1819, rises in the plains at the eastern base of the mountains of Anahuac, and after intersecting the western boundary of Texas in north Lat. 35° and west Long. 25°, pursues a course nearly east, until it is joined by the Kiameche; at its junction with the Kiameche, the Red river curves towards the southeast, and passes into and through the southwest quarter of Arkansas territory, thence into the state of Louisiana, and joins the Mississippi, near the 31° of north Lat. Very little is known respecting the sources of Red river, beyond Cantonment Towson, and indeed the section occupied by that establishment, is represented by all published maps several minutes further south than recent observations for latitude have placed it. The Baron Humboldt, in his account of New Spain, describes the rivers Rajo and Mora, the former rising 25 miles northeast of Tous in New Mexico, and the latter about the same distance east of the town of Santa Fe, as the sources of Red river. The hypothesis of Major Long, that the rivers in question are the head branches of the Canadian fork of Arkansas river, is more plausible, and will no doubt be verified when the country through which those streams flow shall have been subjected to an actual survey. The length of Red river, from its intersection with the western boundary of Texas, to that of Arkansas territory, is 560 miles, and its general course eastsoutheast. It drains an area in Texas of 18,000 square miles.

Sabine river, which forms a part of the eastern boundary of the province, emerges from a dense forest, in N. Lat. 32° 45′, and W. Long. 18° 30′, pursues a southeast course one hundred miles to the point where it is joined by Cherokee creek from the right. At a distance of 30 miles from the mouth of Cherokee creek, the Sabine is intersected by the boundary line between Texas and Louisiana, in N. Lat. 32° and W. Long. 17°. From this point the Sabine curves towards the east, and forms a section of an ellipse, again cuts the meridian of 17° west from Washington, and after a further course of 220 miles, enters the Gulf of Mexico through Sabine lake, in north Lat. 29° 30′. Sabine lake, a mere expansion of the Sabine river, is not more than five or six feet in depth, about twenty miles in length from north to south, and of the mean breadth of four or five miles. Its channel is found with difficulty among the innumerable sand-bars that present themselves, and serve to embarrass and perplex the navigator. A few miles from the discharge of Sabine lake, it becomes contracted, and enters the Gulf of Mexico by a pass scarcely half a mile in width. "This river," says Darby, "affords no navigable facilities worthy of notice. In ordinary tides, it has not more than three feet water on its bar, nor has the lake above five feet, and near its shore still less." Entire length of Sabine river, from its source to the Gulf of Mexico, 350 miles. General course south-southeast. Area of that part of Texas which is drained by the Sabine and its branches, 18,750 square miles.

Neches river has its sources in the salt springs, about N. Lat. 32°, and W. Long. 18° 26′, pursues a southeast course for 140 miles, when it is joined by the Angelina, from the north. At the junction, the Neches assumes a south course, flows 80 miles, and enters Sabine lake in N. Lat. 30°. "The navigation of Neches river," says Colonel Austin, "is good as far up as the Opelousas road," 25 miles above its entrance into Sabine lake. It is 600 yards wide 30 miles from its mouth. Its entire length is 220 miles, and general course southeast.

Trinidad river has its source in the Cross Timbers, in N. Lat. 33° 45′, and W. Long. 21°, and flows in a southeast direction, 160 miles, to the junction with its eastern branch, thence southeast, 60 miles, to another considerable branch, coming in from the east. Continuing the latter course a further distance of 170 miles, it enters the northeast angle of Galveston bay. The entire length of the Trinidad is 390 miles. General course, south-southeast, and it drains an area of 15,500 square miles.

San Jacinto river rises in N. Lat. 30° 45′, and W. Long. 18° 50′, pursues a southeast course for 100 miles, and falls into Galveston bay about 20 miles southwest from the mouth of Trinidad river. The Buffalo bayou, the largest branch of the San Jacinto, flows towards the east, and enters that river about 23 miles above its mouth. It is about 90 or 100 yards wide; "and affords," says Colonel Austin, "good schooner navigation to the head of tide at the forks, eight miles above Harrisburg." Area drained by the San Jacinto and its branches, 3,450 square miles.

Brazos river, the Tanpisarahco or main branch of the Brazos, rises in the great prairies, near the western confines of the province, in N. Lat. 33°, and W. Long. 25° 30′, and flows eastward, 130 miles, into the Great Saline lake of the Comanches. Saline lake is an expansion of the Brazos, and is formed by the innumerable salt springs which abound in its vicinity. The lake is about 20 miles in length from west to east, and of a mean breadth of four miles ; it presents to the traveller a cheering contrast to the monotonous and dreary aspect of the surrounding prairies, whose lengthened and unbroken surface seems to defy the utmost power of vision. Two large streams, the Tosohunova and Keriachehunova, the former coming from the northwest, and the latter from the southwest, enter and serve to augment the volume of Saline lake. Contracting again, at the eastern extremity of the lake, the Brazos resumes its eastern course, which it pursues about thirty miles, to the junction of the Incoqua river, which enters the former from the north. At the mouth of the Incoqua, the Brazos curves towards the northeast, and is joined by the Taray, from the south-west, 45 miles below the Incoqua. Here the river assumes and maintains a general direction towards the southeast, until it falls into the Gulf of Mexico, in N. Lat. 28° 53′, and W. Long. 18° 22′. Many streams successively enter the Brazos, between its source and final discharge into the Gulf of Mexico.

The length of Brazos river is 700 miles. General course southeast. Area drained, 50,000 square miles. The Brazos averages 300 yards in width to Brazoria, and 200 yards from thence to the Waco village. It is navigable at all times to the head of tide, a short distance above Brazoria. In high stages of the water, which frequently occur, small steamboats may ascend the river as far as San Felipe de Austin, 118 miles, and keel boats may reach the Waco village, 268 miles from the Gulf of Mexico. There is a bar at the entrance of Brazos river, thirty yards wide, on which six feet water only can be calculated on with certainty, although it often affords eight and sometimes nine feet. The banks of the Brazos, as well as those of its northern branches, are highly picturesque; and in ascending the mountain region, where the streams precipitate themselves down the rocky cliffs of San Saha, the scenery becomes peculiarly romantic and imposing.

Little Brazos rises a few miles to the east of, and flows nearly parallel with, its recipient. It presents a remarkable feature in the hydrography of this part of the country; its distance from the Brazos does not exceed five miles at any place, sometimes approaching within one mile of that river, and then receding as if unwilling to unite its waters with those of its great rival. Pursuing, thus, its southeastern course of 45 miles, it ultimately enters the left side of the Brazos, 206 miles from its discharge into the Gulf of Mexico.

San Andres Branch, heads in a hilly and sterile region, in north lat. 32°, and west long. 21° 15′, pursues a southeastern course, 100 miles, to the junction with its principal branch, the San Gabriel. At the junction, the San Andres assumes and maintains a direction nearly due east, to its entrance into the Brazos, a distance of forty miles below the forks.

Red Fork of Brazos river rises about 10 miles south east of the Towiash village, situated on the Wishetaw branch of Red river, in north lat. 33° 30′, and west long. 22° 40′, flows nearly east ninety miles, then assuming a south course, and passing through one of those immense prairies which stretch themselves in every direction, a further distance of 100 miles, enters the left bank of the Brazos.

Incoqua, the largest branch of the Brazos, has its numerous sources in the great ridge which divides the waters of the Colorado, Brazos, &c. from those of the Rio Bravo del Norte, about north lat. 34°, and west lon. 25°. Its general course is southeast, and entire length about 200 miles. It intersects the left bank of the Brazos 45 miles above the Taray, and 520 from the mouth of the former.

Tosohunova Branch, heads near the source of the Tempisaraco, and running an eastern course 110 miles, falls into Saline lake on the north side, 555 miles from the Gulf of Mexico.

Keriachehunova, the only remaining branch of the Brazos deserving notice, rises in common with the two streams last mentioned, at the foot of the great ridge, and flowing eastnortheast about 100 miles, unites with Saline lake, a few miles above the Tosohunova.

Very little is yet known of these streams—indeed, the same remark will apply to the entire region in which they take their rise. The delineation of the head waters of the Incoqua, Tosohunova, Keriachehunova, and other water courses in this quarter, can scarcely be regarded in any other light than as a mere sketch of the fancy—the whole of the northwestern portion of the province constitutes, with little exception, a *Terra incognita*, that may stimulate the enterprising inquirer to future discovery.

St. Bernard river, about 130 miles in length, has its source in north latitude 30°, and west longitude 19° 30′, about 35 miles west of San Felipe De Austin. Flowing in a southeastern direction 45 miles, it approaches within three miles of the Brazos; then curving towards the south, again inclines to the eastward, and passes about two miles west of Brazoria. After leaving the vicinity of that village, the St. Bernard turns abruptly, and pursues a south course until it enters the Gulf of Mexico. The St. Bernard is 100 yards wide to the head of tide, about 40 miles from its mouth. Its general course is southeast, and it drains an area of nearly 1500 square miles.

Colorado river has its principal sources among the western mountains; one of these heads in a large spring, north latitude 30°, and west longitude 23° 40′, and pursues a general northeast course, about 180 miles, to its intersection with the north branch, called Pasigano river. From its junction with the Pasigano, in north latitude 31° 30′, and west longitude 22° 10′, the Colorado flows in a southeastern direction, with occasional variations, to its discharge into Matagorda bay, which it enters a little to the southwest of old fort Matagorda, the landing place of the unfortunate La Salle, who was murdered in 1687 by one of his own men, and his colony at Matagorda broken up by a Spanish military force sent from New Leon. The Colorado, although somewhat less in size than the Brazos, is navigable to the hills above the upper road. Its banks are generally low, except among the hills, where, like those of the Brazos, they partake largely of the sublime and romantic character which marks the sides of that stream, and present to the eye of the traveller every variety of picturesque scenery, common to mountainous countries. Entire length of the Colorado, 569 miles; general course, southeast; area drained, 40,400 square miles.

Llano river, about 90 miles in length, rises in the vicinity of the silver mines of San Saba, flows northeast, and joins the Colorado at the base of the Great Peak, 255 miles above Matagorda.

San Saba river, one of the principal branches of the Colorado, rises in the mountains of Piedra Pinta, in north latitude 30°, and west longitude 23°, pursuing a northeast course above 120 miles: it enters the Colorado on the right, 272 miles above its outlet.

Pasigano river is the most extensive branch of the Colorado, being nearly equal in length to the main stream above its intersection with the former. The Pasigano rises in the Great Prairie, near the western boundary of the province, and interlocks its head branches with those of the Brazos. Passing through the lands of the Comanche Indians, it joins the left side of the Colorado 80 miles above Pecan river, and 354 from Matagorda bay. Entire length 190 miles; general course, southeast.

Aguila river rises in the mountains which form the boundary between Texas and the state of Chihuahua, and flowing through a broken and hilly region, which renders its course exceedingly precipitous, enters the Colorado 444 miles from Matagorda bay.

Frio river is the western branch of the Colorado; that from the south, although of less extent, is regarded as the main source of this important river; it heads in a large spring, which issues from the mountains, and forms a stream of considerable magnitude. The distance from the mouth of the Aguila to that of Frio, is 80, and thence to the great spring, 45 miles.

La Baca river, although of limited extent, derives importance from the circumstance of its forming a great part of the western boundary of Austin's colony, and the eastern limit of De Witt's lands. It rises in north latitude 30°, west longitude 20° 20′, and pursues an almost undeviating southeast course, to its discharge into the north arm of Matagorda bay. Entire length 130 miles; general course, south-southeast; area drained, 3100 square miles.

Guadalupe river has its source in the hills of San Saba, and is here called "Rio Verde," which name it retains until it is intersected by a branch flowing in from the northwest, called "Piedras;" thence it passes nearly due east, 70 miles, to the outlet of the great spring, 8 or 10 miles west of the upper road, where, curving gradually towards the southeast, a farther course of several miles, it enters the Bay of Espiritu Santo, due south of, and about 16 miles from the mouth of La Baca. The Guadalupe is navigable for small boats to the lower road at Goliad, above which it is very precipitous in its course, affording mill-seats, and abundance of water for irrigation and other purposes. It drains an area of 13,500 square miles, and has an entire length of 287 miles; its general course is southeast.

San Antonio river is a branch of the Guadalupe, but little inferior in magnitude to that river, rises a few miles to the south of the Rio Verde, and pursues a rapid course towards the southeast, under the name of Medina river, to its confluence with the San Antonio proper, 20 miles southeast of the town of Bexar. Continuing its southeastern course, the San Antonio unites with the Guadalupe about 10 miles from its mouth. It is navigable for boats of small draft to the lower road, but above that point it becomes rapid, and its course much obstructed by falls and cascades, which, while they serve to enrich the landscape, render the stream entirely unfit for navigation. Entire length 275 miles; general course, eastsoutheast.

Aransaso river is a small stream, about 60 miles in length; it is formed by several branches, which rise north of the road leading from Laredo to Goliad, pursues an eastern course, and passing the missionary station of Refugio, enters Aransaso bay.

Nueces river, the boundary between the province of Texas and state of Tamaulipas, has its sources interlocking with those of the Colorado, the first fountain of that river being but a few miles north of the springs from which the Nueces issues, in north latitude 29° 45′, and west longitude 23° 30′. From its principal source in the mountains of San Saba, the Nueces flows nearly south-southeast 60 miles, and then gradually turns towards the southeast, which course it continues to flow until it enters the Gulf of Mexico, in north latitude 27° 30′. Its entire length is 300 miles, and it drains an area of 12,200 square miles.

Rio Frio, the principal branch of the Nueces, heads near the source of that river, and running a southeastern course, enters the left side of the Nueces, 110 miles from the Gulf. Ascending the Rio Frio, the following streams successively present themselves: Puenta de la Piedra 3, Saparita 8, and San Miguel 18 miles above the mouth of Rio Frio. It was near the source of the Saparita, and a few miles south of the town of Bexar, that general Toledo was defeated in 1813. In Texas, although its geological structure, so far as it is known, would naturally lead us to expect interior lakes; yet, with the exception of Saline lake, none of any magnitude have yet been discovered within the borders of the province. Between the Nueces and Rio Bravo, in the state of Tamaulipas, a succession of salt lakes have been discovered. These lakes, although not belonging strictly to the country immediately under review, deserve particular notice, as they have since their discovery yielded, and will, no doubt, long continue to afford an ample supply of salt, not only for the country in their vicinity, but also for the consumption of the southwestern quarter of Texas. The salt lakes of Tamaulipas are situated about 30 miles northeast from Mier, a town of Tamaulipas on the Bravo. "The salt in these lakes," says Col. Austin, "crystallizes at the bottom in strata from four to six inches in thickness." Large quantities of salt are annually taken from them without producing any serious diminution. There are three large and several small lakes, altogether covering an area of 100 square miles.

Face of the country.—Although the southwestern quarter of Texas presents a broken and irregular appearance, no elevations deserving the name of mountain, in its enlarged sense, exist within its limits. In the adjoining province of Coahuila, mountains of great elevation extend in ridges, nearly parallel with, and at a mean distance of 70 miles southwest from, the Rio Bravo. The great peak near Monterey, is called "curra de la Silla," (saddle mountain,) from its resemblance at the top to a Spanish saddle, when viewed from the Salinas road.

The same chain acquires increased elevation near Candela, and can be seen at a distance of 80 or 100 miles, enveloped in clouds, and its high peaks covered with snow during a great part of the year. The entire country, for many leagues southwest of Monclova, is exceedingly mountainous, and generally destitute of timber. The mountain ranges of Texas, in which the Colorado, Guadalupe, and Nueces have their sources, are of the third and fourth magnitude. Those extending along the right side of San Saba river, are probably the highest; their elevations, however, are matter of mere conjecture, as no scientific means have yet been employed to obtain accuracy in this particular. A considerable elevation will no doubt be found on a careful measurement, at the sources of the Nueces, Guadalupe, Colorado, &c.; for while the streams above draw their waters from springs quite remote from each other, we find those rivers, together with the Puerco and several other branches of the Rio Bravo, rising within a circle of less than 50 miles in diameter; thus indicating an elevation far above the surrounding table land. From this nucleus, chains of mountains, or rather high hills, extend in every direction. The one most deserving notice, is that chain which divides the waters of San Saba, from those of the Llano, and is unquestionably a prolongation of the Ozark mountains of Major Long. Before it intersects the Colorado, it attains to an immense height, and forms what is called the "Great Peak," a few miles to the south of the mouth of San Saba, and near the right bank of the former river. Thence it ranges towards the north, separates the waters of Pecan and San Andres rivers, and turning eastward, terminates in a peak on the right bank of the Brazos, nearly opposite to the outlet of Noland river. A spur from this chain extends towards the east, and forms the dividing ridge between the Medina and the upper branches of the Guadalupe.

The great spring of Guadalupe, issues from the eastern end of this chain, which also gives rise to the fountains in the vicinity of Bexar. Another spur leaves the principal chain near the sources of the Guadalupe and Llano rivers, and becoming gradually more depressed, in its course towards the east, is finally lost near the great spring of San Marcas. A succession of sand hills extend from the latter, commencing at the source of the Piedernales, a branch of the Colorado, and passing towards the northeast, subside before they reach the bank of the latter. The fountain of San Lucia is situated in this chain, near the source of the Piedernales. The next chain in point of elevation, leaves the one just mentioned, at the first fountain of the Colorado, pursues a northwest direction, and joins the Guadalupe mountain of Humboldt, about 300 miles from its point of outset. This chain forms the boundary between Texas and the territory of Santa Fe or New-Mexico, and state of Chihuahua, and divides the waters of Rio Bravo from those of the Brazos and Colorado. Its mean elevation must be considerable, and will no doubt be found, on a careful examination, to exceed in height the mountains of San Saba, which are generally regarded as the most elevated. The third chain in the order, extends towards the northeast, divides the waters of Piedra Pinta from the San Saba and Conchas rivers, and is pierced by the Colorado, below its junction with the Pasigon. Thence it continues its northeastern direction, between the Piaroya and Ontejunova, joins the chain first described, near the source of Pecan river, where a spur leaves it, and passing between the Pecan and Wisshonca, forms a high peak, and then rapidly subsiding, terminates near the Colorado.

The fourth and last chain worthy of notice, extends southeastward, and separates the waters of the Medina and Rio Frio, a large branch of the Nueces. Near the source of the Rio Frio, a broken ridge leaves the main chain, passes towards the southeast, and divides the upper waters of Rio Frio from the Nueces. At the foot of this chain, and over the plain which extends on both sides of the Nueces towards the Gulf of Mexico, are found those countless droves of wild horses, which give animation to a region otherwise desolate and dreary. Most of the rivers which have their sources in the northeastern part of the province, flow through open plains of grass, into the marshes which line the southeastern coast of Texas, in common with the southern portion of the adjoining state of Louisiana. The whole of the northeastern part of the province is undulating, with hills of moderate elevation. These, however, entirely subside on leaving the forests, and near the gulf coast nothing is to be seen but a monotonous level of prairie and sea marsh. Advancing westward, a rapid improvement in the soil and general aspect of the country is perceptible. The lands near the coast become more elevated and dry; marshes, which abound to such an unlimited extent in the southeastern quarter, almost wholly disappear on approaching the valley of the Brazos.

West of the Brazos, and southeast of the mountain region, if it can be so called, extends a vast plain, whose inclination, as indicated by the water courses, is very considerable. As this plain approaches the alluvial border, its inclination sensibly diminishes, and a comparatively level surface is presented along the whole extent of this formation. Although the country between the coast and the lower road is very level, it is nearly free from marsh, and west of Galveston bay it is entirely so.

Northwest of the mountain region, which, as has been stated, lies in the central and southwestern parts of the province, immense prairies, covered with grass, and affording inexhaustible pasturage for cattle and horses, occupy the entire space between the "Cross Timbers" and the northern and western confines of the province. The Cross Timbers, so called, constitute a singular feature in the northern part of the province; they consist of a dense growth of forest trees, some of them of a prodigious height, and extend in a strip about 300 miles in length, and not exceeding 20 miles in mean width, nearly due north from the Waco village, on the Brazos, to the Arkansas river. This forest, which may be justly ranked among the natural curiosities of the country, forms, by its peculiar appearance, a striking contrast to the dull and monotonous prairies on either side. The lines which mark its limits are so completely defined, as almost to induce a belief, that art had been employed in giving form to this extraordinary work of nature.

Climate, soil, and produce.—In the central and northern parts of Texas, the climate is highly salubrious, and may, when its geographical position and southern exposure are taken into view, be regarded as a comparatively cold region. The winters, in those parts, as in the corresponding portions of Coahuila, are generally cold, and sometimes severe. Near the coast, and especially in the southwestern quarter of the province, the climate is greatly affected by the long droughts which prevail, and, in connexion with its relative depression, serve to increase its mean temperature far beyond what the difference of latitude between its northern and southern sections would lead us to expect. Rains in this quarter rarely fall, but when they do occur, they fall in torrents. The excessive rains that sometimes deluge, and the protracted droughts which occasionally parch, the southwestern parts of Texas and the northern portions of Tamaulipas, are among the most remarkable phenomena of physical geography. From these, and more local causes, the climate of Texas generally presents less uniformity of temperature than most other countries in similar latitudes. A great portion of the country is entirely exempt from those stagnant swamps and pools which constitute a fruitful source of disease in most of the southern states, where the periodical pestilence, and almost infinite variety of febrile affections, common to the maritime sections of those states, may be ascribed to the malignant effluvia of extensive swamps and marshes, which abound to an extent so frightful. This exemption from such receptacles of disease, gives to the province a decided advantage over its eastern neighbour the state of Louisiana, whose southern border consists almost entirely of sea marsh, intersected by stagnant ponds of all dimensions, which serve no other purpose than to engender disease. The entire structure of this province appears to be essentially different from that of Louisiana. In the latter, especially within a hundred miles of the gulf coast, the lands decline from the banks of the rivers, and fall into swamps, which uniformly maintain a lower level than the river banks. On the contrary, in Texas, the lands gradually ascend on leaving the streams, and are backed by rolling prairies, which afford in many places plantations of considerable extent. Beyond the alluvial border, which extends about 60 miles from the gulf coast, the prairies commence, and reach to the timbered uplands. The alluvial lands, particularly the borders of the large streams, are thickly covered with the different varieties of oak, elm, cedar-wood, alder, dog-wood, walnut; and every other species of timber, common to such regions, is found in great abundance east of the San Antonio; but west of that river it becomes scarce, many extensive tracts being completely destitute of this important article. These lands are interspersed with extensive cane brakes, and are considered by planters as well adapted to the cultivation of sugar, cotton, indigo, &c., and for grazing to an unlimited extent. Wheat, corn, and the various kinds of provisions, can be successfully cultivated throughout the whole of the northern parts of the province. The luxuriant growth of the cane in the southern part, justifies the belief that sugar will become one of its most important productions. Already has this valuable commodity been produced as an experiment in the vicinity of San Felipe de Austin, with the most flattering prospects of success.

Population and settlements.—The entire population of Texas, including the Indians, does not exceed 12,000 souls; and a considerable portion of this number is included within the limits of Austin's colony. The remaining part of the civilized population is confined chiefly to the towns of Bexar, Goliad, Nacogdoches, &c. In 1821, when the enterprising Austin commenced the settlement of the lands acquired by him, Texas was with few exceptions an entire wilderness, from the Sabine to the San Antonio. Its white inhabitants were few in number, and consisted of Spaniards and their descendants, together with some emigrants from the United States. The whole country was filled with hostile Indians, who, having no fixed residence, roamed unrestrained over the plains, committing with perfect impunity all kinds of excesses. Nacogdoches had been destroyed and abandoned; it has since however recovered, and the town and surrounding country are now in a flourishing condition.

Austin's colony was founded in 1820, by Moses Austin, the father of the present proprietor, under a grant obtained from the commandant-general of the eastern internal provinces. By the terms of this agreement, Mr. Austin was required to establish, within a specified time, 300 American families in the newly acquired territory; but, although many families from the United States had previously fixed themselves in Texas, the actual settlement of the colony was not begun until the year 1823, when Col. S. F. Austin, in consequence of the decease of his father, assumed the fulfilment of Mr. Austin's contract; and, under the sanction of the political authorities of Mexico, commenced the location of the emigrants. Such is, briefly, the history of this interesting community.

This colony, including the grant to Col. Austin, of 1827, embraces an area of 19,000 square miles; it is situated between the 28° and 31° of north latitude, and 18° and 21° of west longitude from Washington city, and is watered by the San Jacinto, Brazos, Colorado, La Baca, and some other streams of minor importance. San Felipe de Austin, the principal town, is built on the right bank of the Brazos, about 118 miles from its discharge into the Gulf of Mexico. The great road leading from New Orleans to Rio Grande, Monclova, &c. passes through, and divides the town into two nearly equal parts. The town and surrounding settlements, which are rapidly increasing in numbers, present a scene of active industry rarely met with in other parts of the province. Several good elementary schools have been established in the colony, and in those of San Felipe some of the higher branches of an English education are taught.

Brazoria, also a thriving town, is situated on the west bank of the Brazos, 24 miles above its mouth.

The town of Harrisburg, on the Buffalo bayou, a branch of the San Jacinto, promises to become a place of some consequence, and will no doubt figure in the future history of the province. Both Brazoria and Harrisburg are accessible from the Gulf of Mexico, by vessels of considerable burthen.

The colony has now a population of about 4000, consisting almost exclusively of Americans;—one steam saw-mill, and a considerable number of cotton gins. Its produce is sugar, cotton, wheat, rye, Indian corn, &c., with an abundance of timber of various kinds. The produce of the last season consisted of 1000 bales of cotton, 150,000 bushels of corn, and 140 hogsheads of sugar. The cotton raised in the colony is mostly shipped to New Orleans for a market, and the surplus corn and other produce are sent to Matamores, Tampico, and Vera Cruz. The greater part of the inhabitants are agriculturalists. Grazing receives a due share of attention, as it affords a handsome profit with very little labour, and no other expense than is attended by occasional herding. The local government of the colony is administered by officers elected by the settlers; these officers consist of an alcalde, who has civil and judicial jurisdiction, two regidores (aldermen), and one syndic, forming a municipal body, styled ayuntamiento, of which the alcalde is president. The alcalde and one of the aldermen are elected annually, and cannot be re-elected until two years after their retirement from office.

De Witt's colony lies immediately west of, and adjoining, that of Colonel Austin, the La Baca being the line of separation between those two colonies. It embraces an area of 3500 square miles, and is watered by the Guadalupe, which, with some of its numerous branches, serve to irrigate its soil. No settlements of importance have yet been made in this colony.

Ectar's Grant, so called. Much has been said in the public prints respecting a grant alleged to have been made by the Mexican government, comprising an area of nearly 63,000 square miles (40,000,000 acres). Where this immense tract is, or where it can be located, it is difficult to conceive, unless all the previous grants, which are numerous, shall be abrogated: should such a grant have been made in addition to those already located, there will remain but a small portion of Texas for future purchasers. Although it is well known that the Mexican government pursues a liberal policy towards actual settlers, in granting them lands on the most favourable terms, it can scarcely be credited, that a cession nearly co-extensive with the unappropriated parts of the province should have been sanctioned by that government, by which no title has recently been given, except to the class of purchasers just mentioned. Land can be obtained by emigrants with great facility from the empresario, (founder of the colony,) and from the commissioners of the government, under the colonization law, which authorizes the grant to families, who are actual settlers, of one Mexican league, equal to 4446 acres. Unmarried men can obtain the fourth part of that quantity, the expenses of which will not amount to four cents the acre.

Nacogdoches, Bexar, Victoria, and Goliad, formerly called Bahia, are the only towns remaining to be noticed. Nacogdoches is situated on the head waters of Neches river, in the eastern part of the province, and about 160 miles, in a direct line, from the gulf coast. It is on the great road leading from New Orleans and Natchitoches, in Louisiana, to the city of Leona Vicario, the capital of the state of Coahuila and Texas, and is 728 miles northeast from that city. Fort Nacogdoches, the germe whence the town of that name sprung, was erected shortly after the first settlement of the country, and was for a long period the only settlement in this part of Texas. The town itself never attained to any importance in point of population, and its commerce was chiefly confined to the supply of the garrison, and a small trade with the surrounding Indian tribes. Since its destruction in 1821, the town has been rebuilt, and the number of its inhabitants considerably augmented by emigrants from the United States.

Bexar, or San Antonio de Bejar, the former capital of the province, is situated on the western prong of Salado creek, an inconsiderable branch of the San Antonio river, 393 miles southwest from Nacogdoches, 153 west from San Felipe de Austin, and 335 miles north-northeast from Leona Vicario.

Goliad is situated on the right bank of San Antonio river, about 40 miles above its entrance into Espiritu Santo bay, and 115 southwest from San Felipe de Austin. Goliad, like Bexar, is a place of but little importance, although built more than half a century. Neither Bexar nor Goliad can be regarded in any other light than as mere villages. The latter possesses some advantages over the other from its proximity to the gulf, the San Antonio being navigable for vessels of small draft as far up as Goliad.

Victoria, on the left bank of Guadalupe, is a village of the smallest class, but is said to be improving.

The "Upper road," or that leading from New Orleans by Natchitoches, &c. to the city of Mexico, intersects the Sabine about 45 miles west from Natchitoches. After crossing the Sabine, it pursues a little south of west, until it reaches Nacogdoches; thence turning towards the southwest, it proceeds to Bexar, where it assumes a more southern direction, and intersects the Nueces about 150 miles from the Gulf of Mexico. In its course from Nacogdoches to the Nueces, this road successively crosses the Trinidad, Brazos, Colorado, Guadalupe, and San Antonio rivers. It is 98 miles from Natchitoches to Nacogdoches, thence to the Trinidad 78, thence to the Brazos 59, to the Colorado 60, Guadalupe 58, town of Bexar 40, Nueces 105, and thence to Leona Vicario 230 miles.

The Lower road, so called, leads from New Orleans, via Opelousas, to the town of Goliad. It crosses the Sabine 30 miles above its discharge into Sabine lake, and follows a south-west course, at a mean distance from the gulf coast of fifty miles, passes through San Felipe de Austin, and intersects the Nueces 469 miles from Opelousas.

Other roads have been opened. Among these are the following: from San Felipe de Austin to Brazoria 70, and thence to the mouth of the Brazos 25 miles, to the Old Fort on the Brazos 38 miles, to Harrisburg 45 miles, to Victoria 110, and thence to Goliad 22 miles,—to Matagorda 95 miles. Many improvements of this kind have been made, and some others are contemplated.

From the geographical position, and the character of its soil and climate, Texas will probably become the great vineyard of America. Every variety of grape, of the most delicious flavour, is found growing spontaneously throughout the entire province. On the table lands between the Cross Timbers and the sources of the Sabine, immense tracts of country are literally covered with the various species of grape, which attain to an uncommon size. The orange and other fruits, such as the fig and the different kinds of the raisin grape, will also find a genial soil in the southwestern parts of the province, where the climate and general nature of the atmosphere are admirably adapted to the exiccation of those fruits, especially that of the common fig. The latter is produced in great abundance in most of the southern states and Florida, but owing to the humidity of the atmosphere of those states, it rarely becomes sufficiently dry, for want of that peculiar warmth which is necessary to its preservation for commercial purposes; hence this valuable fruit, which constitutes an important article of commerce of Turkey, Italy, and some other countries, is cultivated in America merely for table use. The causes which have operated in the southern states to prevent the successful preparation of the raisin, do not exist to the same extent in Texas; we may, therefore, expect to find, some years hence, this useful article also among its most lucrative staples. See *American Quarterly Review*, vol. vii. 1830.

H. S. Tanner.

THALES, the founder of the Ionic school, was born at Miletos about 600 years before Christ. In quest of wisdom he travelled to Crete and to Egypt, and he is said to have acquired his mathematical and philosophical knowledge from the priests at Memphis. An account of his labours have already been given in our article Astronomy, Vol. II. p. 551.

THAMES. See England, Vol. VIII. p. 512.

THANET, Isle of. See Kent.

THEBES. A very full account, with descriptions and drawings of the remarkable antiquities of this city, have already been given in our article Civil Architecture, Vol. VI. p. 371 and p. 524, &c. See also Egypt, Vol. VIII. p. 222, &c.

THEMISTOCLES. See Athens, Vol. III. p. 19—22, &c. Greece, Vol. X. p. 66.

THEODOLITE is the name of an instrument for measuring horizontal and vertical angles in land-surveying. We have entered so fully into the details of the construction and adjustment of circular instruments under the article Circle, that it is unnecessary to give any account of the Theodolite, which differs from them only in name and application. See Circle, Vol. VI. p. 332. A description of Ramsden's Great Theodolite used in the trigonometrical survey, will be found in the *Philosophical Transactions*, vol. lxxx. 1790, with all the parts of it described in four large plates.

THEOLOGY.

THEOLOGY is the science which treats of the nature and character of God, and of the religious duties and hopes of man.

All mankind are interested in knowing something of the God whom they profess to worship. From the power which they ascribe to him, they must necessarily conclude that their fate is in his hands, and that their happiness or misery depend on his pleasure. It cannot, then, but be deeply interesting to inquire into the character of the supreme Ruler, that we may know how to secure his favour, and how to avoid such actions as may be displeasing to him. These considerations have always operated, and induced an anxious desire to become acquainted with the nature of God, as lying at the foundation of the duties and hopes of men.

In rude states, theology, in the form of superstition, is the only species of study which engages the attention. The priests, augurs, and divines, are thought to be the only persons possessed of useful knowledge; and they have, in general, great influence in the state, either by swaying the public counsels, or by lending the sanction of religion to the measures adopted. Of all the nations of antiquity, the Romans had the highest character as a religious people; and they were well entitled to their pre-eminence, in so far as regards the formalities of worship. As they arrived at vast power, without going through a previous process of refinement, their history exhibits the curious phenomenon of a most splendid system of external worship, connected with the most absurd and irrational creed.

The Greeks thought more deeply on the subject, though not to much better purpose. Many of their sages were substantially, if not professedly, atheists; for they denied the providence of God, and questioned the wisdom of his arrangements in the system of nature: others of them were pantheists, believing the universe to be God, and conceiving that all things were ultimately absorbed into his essence; an opinion which differs not widely from atheism, in its practical consequences; and the greater part of even the most orthodox among them, were fatalists, conceiving that the gods were only instruments in the hands of Fate, and that Jupiter himself had only the power of ascertaining, not of altering its determinations.

Almost the whole literature of Hindostan is theological. The national poetry turns on the incarnations and exploits of the gods; and the order of the priesthood enjoys a pre-eminence superior to royalty itself, having managed to retain the chief honour and consideration in the state, whilst it has transferred to another class all the trouble and odium of government.

These facts show the importance which has always been attached to the study of theology; and considering how intimately the subject is connected with the best interests and hopes of men, we cannot but perceive that the importance of the study has not been overrated. In fact, society cannot exist without some religious influence. The principles of rectitude have never been found, nor indeed have they ever been supposed to be sufficiently strong to resist temptation, when separated from considerations of religion; and imperfect as its influence is, the security of society arises more from the influence of religious belief, and the conscientious scruples which it produces, than from prohibitory statutes and penal enactments.

A subject of such deep and universal interest, must naturally have engaged the highest faculties of the human mind: but it is melancholy to observe to how little purpose they have been exerted. They who have left the most indubitable monuments of genius, and specimens of taste and eloquence which must serve as models; so long as elegant literature has any value in the world, have betrayed the most incredible ignorance on the subject of religion; and the value of revelation is manifest in this, that a school boy in a Christian country, and educated in Christian principles, has more accurate and more philosophical information respecting the nature and government of God, than is to be found in all the writings of the wise men of Greece and Rome put together.

The necessity of a divine revelation was virtually acknowledged by the heathens themselves. They considered the nature and will of the gods, as things necessary to be known, but as too vast for the human intellect to discover. Hence all their legislators who established their civil and religious polities, were regarded as *Theodidacti*, or taught of God. They would have reckoned it impiety to suppose that the knowledge of God could be acquired by the natural resources of human reason; and had they been sufficiently sensible of their ignorance and their misery, they might have concluded that a more perfect revelation than they had yet received, would, in due time, be communicated. For, if man is placed in the world for the purpose of happiness, as they very generally supposed, it was reasonable for them to expect that a specific rule would be given to conduct them to the end proposed, and that they should not be left entirely at the mercy of the varying and contradictory opinions of men. On a view of the whole case, indeed, it appears not so wonderful, that a general revelation should have been given, as that it should have been so long withheld.

Very satisfactory reasons, however, may be assigned why the gospel was so long withheld; at least, we can discover many important advantages to the cause of truth, resulting from this circumstance. There could have been no fulfilment of prophecy, had Christ been completely manifested immediately on the fall of our first parents; and Christianity would thus have been deprived of one of the strongest evidences of its divine origin and authority. Our Saviour and his disciples always laid particular stress on this species of proof, and dwelt on the completion of the prophecies, in the person of Jesus of Nazareth, as furnishing the most satisfactory evidence, that he was the Messiah whom the Jews expected. *We have found him*, says one of the first disciples, *of whom Moses in the law and the prophets did write, Jesus of Nazareth, the son of Joseph.* By the length of time, which elapsed between the fall of man, and the manifestation of the Son of God; and by a great variety of intervening prophecies and remarkable events, we are enabled to view the gospel, not as a detached and anomalous dispensation, but as connected with all the measures of the divine government since the beginning of the world. There were obstacles enough to the reception of the gospel, in the passions and prejudices of the human heart; these obstacles would have been increased in a tenfold degree, had the world been taken by surprise, without any previous intimation of the stupendous plan which was afterwards revealed. It would have been a strong objection to it, had men been able to say, "We never heard any thing of this before," and had its advocates not been able to show from prophecies, and a long train of preceding events, that the world had been prepared for the complete development of it in the person of Jesus of Nazareth.

Another advantage was gained by the length of time which intervened between the fall and the recovery of mankind. They had an opportunity of estimating the character and resources of human nature. Had the important information, afterwards communicated by the gospel, been imparted immediately after the fall, had it been diffused among the first race of men, and by them transmitted to their descendants, we should not have been able at this day to decide, whether we had derived it from a divine revelation, or from our own resources. But the ignorance, misery, and sin which overspread the world during the reign of heathen darkness, contrasted with the light, the purity, and the consolations of the gospel, show us how much we owe to the mercy and goodness of God, and give us the most humiliating view of our natural helplessness and sin. But though, for wise reasons, a general revelation was long withheld, a partial revelation was no less wisely given to a particular people, that the will and the gracious intentions of the Almighty might stand recorded; and that mankind might see that he had never forgotten their interests, but was steadily carrying forward the plans of his mercy, even when the world was lost in trespasses and sins.

Religion is usually divided into natural and revealed; but it is easier to make the division, than to fix the boundaries of each. The distinction, indeed, does not appear to be at all necessary; for it is obvious that the religion of nature, as it has been called, has no doctrines peculiar to itself, and none that it can challenge as its own undisputed property. The existence of a God and a future state, providence, prayer, and public worship, are supposed to belong to the province of natural religion, because they can be established by reason, and because they have found a place where no revelation was known to exist. But all these articles of faith and of practice lie at the very foundation of revealed religion; whose object is to explain them in all their bearings and tendencies on the characters and hopes of men; whilst, in the course of this process, it brings to light many important facts and doctrines, which had eluded all the scrutinies of human reason.

Revealed religion, then, embraces all that is claimed for natural religion, and a great deal more; and, whilst we are at no loss to point out doctrines peculiar to revelation, we cannot point out a single doctrine which we can pronounce to be peculiar to natural religion. We cannot be sure that even any part of the religious knowledge contained in the popular creed, or in the philosophical speculations of the heathen, is the produce of unassisted reason. It is not enough to say that they had no revelation, and therefore their religious knowledge must have arisen out of their own resources. In the early ages of the world direct revelation was imparted to few; but *traditional* information prevailed among all; in consequence of which, much knowledge, originally derived from revelation, might be diffused among mankind. This, at least, we may be certain of, that man, on his first creation, possessed the knowledge of God, either by revelation or intuition: it was not acquired by the usual processes of discipline and experience. Adam, on his creation, must have been endowed with knowledge, otherwise he would never have lived to acquire it, but would have fallen the victim of his own ignorance, before he obtained the knowledge useful to direct him. His children, however, were placed in very different circumstances; reared from an infancy of helplessness and ignorance, they gradually rose to the knowledge of God, in consequence of parental instruction. The information which they had thus received they transmitted to their descendants, who carried it with them into their various settlements, and thus diffused the knowledge of God over the face of the earth. The corruptions which speedily took place in religion, and the varieties of worship which prevailed among nations widely different from each other in situation and circumstances, are exactly such as might have been expected; whilst, at the same time, we may expect among all the varieties of religious forms and opinions, some features of resemblance to connect them all with primeval tradition.

We do not, however, affirm that the mind, enlightened by general knowledge, would not arrive, even without the aid of revelation or tradition, at some idea of a first cause, or presiding principle. It seems next to impossible for a mind which has formed a notion of power and causation, (and these surely are among the first and strongest impressions which the mind receives, and are perfectly plain to all but those who attempt to account for them,) not to conceive of a power superior to that of man, as necessary for the production and arrangement of the visible phenomena of nature. The mind, indeed, is marvellously backward to form right conceptions on this subject; for though the invisible things of God are clearly seen, being understood by the things that are made, yet men *changed the glory of the incorruptible God into an image made like to corruptible man, and to birds and to four-footed beasts and creeping things.* Rom. i. 20. But the question is not whether men could acquire *right* conceptions of God, but whether they could acquire, by unaided reason, any conception of him at all: and we cannot but think that a mind, though ever so little improved in general knowledge, must entertain some idea of a first cause, on contemplating the visible universe.

It is natural for a child when he looks on the visible heavens to ask, who made these things? He never supposes that they exist there without a cause: the first impression of unsophisticated nature is, that they have been produced; and the next step in the process of reasoning is, that they have been produced by some being possessed of power infinitely superior to that of man. Such, we think, would be the first impressions of the mind of man with regard to visible phenomena. But we are not sure but, if he carried his reasoning the length of philosophizing, he might reason himself out of these obvious impressions, and ascribe the whole to fate or chance; or might suppose that they have existed, and will continue for ever to exist, as we now see them. We apprehend, then, that all the religious knowledge which the unenlightened mind could receive would never rise above superstition; and they who affected a more liberal creed, or attempted to establish a more liberal system, found no other way of emancipating themselves from what they saw to be prejudicial, than by setting aside the idea of an intelligent first cause, and thus abolishing all religious obligation.

Although, then, we do not deny that the natural reason of man affords some light, yet it is evidently insufficient either for direction or consolation. It presents objects through an obscure medium, which so completely distorts and alters their real proportions, that, in many instances, it is little better than absolute darkness. Besides, whatever we may advance or admit as to the capacity of human reason for religious discoveries, rests entirely on theory and assumption; for in no one instance can we affirm, that it has made a single discovery of this nature. All the religious systems in the heathen world were evidently traditional: they are all connected with each other by some striking features of superstition, which are inventions and not discoveries, the figments of human fancy, and not the offspring of reason; and whenever the heathens make any approach towards a rational creed, it will probably be nearer the truth to ascribe their knowledge to some borrowed light derived from tradition or revelation, than to regard it as the result of their own investigation. Believing that all mankind are descended from a common stock, we may naturally expect some vestiges of a common creed, in consequence of traditional information. These resemblances and coincidences we observe in the sacrifices and rites of expiation, which were adopted by all nations. And farther, if we believe that the Bible gives the most ancient and the most accurate account of the primeval religion of men, and of the peopling of the earth, we may naturally expect to find a strong resemblance to the Scripture creed, among the various tribes of mankind, particularly in the earlier periods of the world. This resemblance can, in many instances, be distinctly traced. The history of the creation, for instance, as recorded by Moses, was adopted by all the nations of antiquity. Megasthenes, who lived in the time of Seleucus Nicator, affirms that all the doctrines of the Greeks, respecting the creation of the world and the constitution of nature, were current among the Bramins in India, and the Jews in Syria. We are inclined to think that Ovid must have had the sacred volume before him, (the Septuagint translation, no doubt,) when he wrote his account of the creation. The coincidence is too striking to be accidental. He first describes the chaotic state of matter, before the Creator arranged it in its various forms; the next step was to divide the heavens from the earth, and the earth from the waters: he then mentions fishes as the first living things of this world, and goes on to state the formation in the other creatures, till the work was crowned with man. In this account it is evident that the heathen poet has not only adopted the facts, but the order of the creation as given by the sacred historian; and when we consider what follows about the war of the giants, the general corruption of mankind, the universal deluge, the preservation of Deucalion and Pyrrha, &c. &c. it is impossible to doubt that Ovid has borrowed directly from Moses. In this case the plagiarism seems fairly detected. At the same time, Ovid gives the general account which was current among both Greeks and Romans; and therefore we have reason to conclude that they all borrowed from the same source. The imagination of the Greeks soon disguised the traditional accounts which they had received of the early history of mankind, with the most extravagant fables, and converted the early history of religion into a system of the most absurd mythology. They have done irreparable injury to ancient history by the mere circumstance of translating proper names, and then inventing a history to correspond with the translated meaning; whilst the Egyptians rendered any religious knowledge which they possessed perfectly inaccessible by the veil of symbols and allegories under which they concealed it. The only inventions of human reason in matters of religion have been to obscure what was plain, to mystify what was simple, and to degrade what was sublime, by unavailing attempts at explanation and refinement.

It is not an easy matter, then, to define the limits of reason in religion. What it can do we can only conjecture; having no certainty that there is one article of the religious creeds which have been current among men, that can be set down as the result of unassisted reason. Were we inclined to preserve the distinction between natural and revealed religion, we would not limit the former by attempting to draw a strict line of demarcation between it and the doctrines of revelation; but we would consider as within its province all those doctrines which, whether they have been the result of reason or not, are at least cognizable by it, and capable of being established by its deductions, though they may not have been discovered by its researches. This is extending the boundaries of natural religion, without encroaching on revelation: it is only giving reason the advantage of all the light which revelation has imparted, and considering as within its legitimate province those matured results which correspond with its dictates, though they may have originated in revelation. Of this kind are the doctrines respecting God, providence, a future state, &c. which have been set in the clearest light by revelation; yet our improved knowledge on these subjects is so perfectly conformable to the dictates of natural reason, that we can scarcely persuade ourselves but that reason, by its own efforts, might have reached them.

The doctrines peculiar to revelation are of a different description, and easily distinguishable from those mentioned above. The trinity, incarnation, atonement by Christ, resurrection of the body, &c. are doctrines not discoverable by reason. But we are not on this account to suppose that they are not proper subjects of reasoning. They may be established by argument, by ascertaining the genuineness and authenticity of the records in which they are contained, and the value of the testimony on which they rest; and by considering, at the same time, the reflex light which they cast on the government of God, and on the character and condition of men. We are farther to consider, that though the doctrines peculiar to revelation could not be discovered by human reason, nor, even after they are known, can they be comprehended by the human faculties, yet in no instance do they contradict the dictates of enlightened reason: they are above it, but not contrary to it. It would be absolutely impossible to believe a revelation which contradicts any ascertained principle of pure reason. This may be considered as an axiom in theology; for a revelation must come from the same being who has formed the mind of man and the constitution of nature; and we cannot conceive that the word of God can ever contradict his works, or that he should command us to believe any doctrine which the reason he has given us compels us to reject. But in admitting this axiom we must be extremely careful to free reason from the influence of the passions, and from the power of those prejudices which tend to bias its decisions, otherwise we will measure doctrines and facts, not by the standard of reason, but by the strength of our inclinations and feelings. Revelation has certainly nothing to fear from the strictest scrutiny, provided it be fairly conducted; but it has no chance before a prejudiced judge, against perjured witnesses, and a corrupted jury.

But from the influence which we have ascribed to revelation and tradition, in forming the religious creed of mankind, a greater uniformity of opinion may perhaps be expected; and it may probably be thought that some traces of all the doctrines of revealed religion ought to be found even amidst the mythology and fables of the heathens. Many contend that this is actually the case; but we think they carry their arguments too far. We hold that no traces of many of the important doctrines of revelation are to be found in the religious creed of the heathen; and for this reason, that these doctrines were withheld from the world, except in the obscure imitations of figure and prophecy, till the period of the Christian revelation; and therefore they could only be known where that revelation was announced and received. It has been said, for example, that the doctrine of atonement for sin was no new doctrine, since it has a place in the creed of all nations, inasmuch as they have all trusted in expiatory sacrifices. This, in a certain sense, is true: the practice of sacrificing has been almost universal, and its object has always been the remission of sins, or the procuring of blessings. It is difficult to account for this practice, as the offspring of reason: it is not difficult to trace it to the Scripture history; for we read that Cain and Abel, the first-born of the human race, offered sacrifices to God. It is not said, however, on what authority they did so. We are inclined to ascribe it to a divine injunction which is not recorded; the more particularly, as God afterwards saw it expedient solemnly to enjoin the practice to the Jews. If it is the offspring of reason, Cain must have the honour of the invention, as he is mentioned as the first who sacrificed to God.

But whether the general practice of sacrificing arose from this primeval source, or whether it is an invention within the ordinary reach of human reason, this at least is certain, that the Scripture doctrine of atonement through Christ was altogether a new doctrine, except in so far as it was announced in the predictions of the prophets. It is altogether beyond the reach of human reason; and appeared so strange, that, with all the aid of previous education, it was a stone of stumbling and a rock of offence, both to the Jews and Gentiles. We need not be surprised then, that the doctrine in this shape should have no place in the creed of the ancient heathen, since it was concealed even from the people of God, till *the fulness of time*, when every thing in the plans of providence was ripe for its disclosure.

We do not mean to attend any farther to the distinction between natural and revealed religion There are, no doubt, some grounds for the distinction, if not in reality, at least in our conceptions, and in our manner of viewing the subject. But we know not where the line is to be drawn; we are inclined to think, that if it is not an imaginary, it is at least a movable boundary, which will gradually disappear as we advance in knowledge; and when, at last, "we shall know even as we are known," the most mysterious parts of the Christian revelation will be found to be as essentially connected with the nature and government of God, as his providence, or any of his most obvious attributes. It is no mark of reason to affect to despise the resources of human reason; and still less to slight the light of revelation, which alone can conduct our reason to just and profitable conclusions. Reason is the compass by which we steer our course; revelation is the polar star by which we correct its variations.

We are to look to the word of God, then, as contained in the Scriptures of the Old and New Testaments, for the only sure rule of faith and practice. But there is this singularity in the sacred Scriptures, that we do not find in them a set treatise on any one of the interesting subjects which engage our attention as moral and religious beings. No attempt is made to prove the existence of a God; such an attempt would have been entirely useless, because the fact is universally admitted. The error of men consisted not in denying a God, but in admitting too many; and one great object of Scripture is to demonstrate, that there is but one. No metaphysical arguments however are employed for this purpose. The proof rests on facts recorded in the history of the Jews, from which it appears that they were always victorious and prospered so long as they served Jehovah, the name by which the Almighty made himself known to them; and uniformly unsuccessful, when they revolted from him to serve other gods. What argument could be so effectual to convince them that there was no god in all the earth but the God of Israel? The sovereignty and universal providence of the Lord Jehovah, are proved by predictions delivered by the Jewish prophets, pointing out the fate of nations and of empires, specifying distinctly the cause of their rise, the duration of their power, and the reason of their decline; thus demonstrating that *one* God ruled among the nations, and made them the unconscious instruments of promoting the purposes of his will. In the same manner, none of the attributes of God are demonstrated in Scripture by reasoning: they are simply affirmed, and illustrated by facts; and instead of a regular deduction of doctrines and conclusions from a few admitted principles, we are left to gather them from the recorded feelings and devotional expressions of persons whose hearts were influenced by the fear of God.

These circumstances point out a marked singularity in the Scriptures, considered as a repository of religious doctrines. The writers, generally speaking, do not reason, but exhort and remonstrate; they do not attempt to fetter the judgment by the subtleties of argument, but to rouse the feelings by an appeal to palpable facts. This is exactly what might have been expected from teachers acting under a divine commission, and armed with undeniable facts to enforce their admonitions.

But though there is no regular treatise in the Scriptures on any one branch of religious doctrine, yet all the materials of a regular system are there. The word of God contains the doctrines of religion in the same way as the system of nature contains the elements of physical science. In both cases, the doctrines are deduced from facts, which are not presented to us in any regular order; and which must be separated and classified before we can arrive at first principles, or attain to the certainty of knowledge; and in both cases, a consistent system can only be made out by induction and investigation. The very circumstance of no detailed system being given, renders it necessary to form one; for although a portion of religious and physical knowledge sufficient for the common purposes of life, may be obtained by traditional information, and men may work conveniently enough by rules without possessing much general knowledge; yet they who would teach with profit, must generalize, and they who would explain the ways of God must arrange the materials which are so amply furnished, but which are presented apparently without order or plan.

We would therefore consider all objections to systems of Divinity to be about as unreasonable as it would be to object to the philosophy of Newton, for having elucidated the laws of nature, and arranged the phenomena of the heavens. A man totally unacquainted with natural philosophy may get comfortably enough through life, for he can work by rule, though ignorant of the principles on which the rule depends. But when a change of circumstances requires a variety of practice, his want of science will appear, and his attempts at renovation will lead to misapplied labour, injudicious expense, and ultimately to disappointment. Ignorance of the principles of religion may be attended with still worse consequences. The ways of God are very complicated; the manifestations of his will are infinitely diversified, and sometimes appear as if they were opposed to each other; and it is only by an enlarged view of his dispensations, and a careful comparison of the procedure of his providence, that we can see the beauties and estimate the value of that revelation which he has given. It is the greatest of all mistakes to suppose that a revelation has been given to save us the trouble of thinking; its object is to teach us to think aright, to prevent the waste and misapplication of our faculties, but not to supercede their exercise. And though we are fully persuaded that no degree of study would ever have enabled men to arrive at accurate conceptions of God and of his government, without the aid of revelation, we are no less certain that revelation itself will not endow men with religious knowledge without study, meditation, and reflection. We do not mean to say that very profound study is necessary to make a good practical Christian: they who are imbued with the spirit of Christianity are led, as it were instinctively, to a conscientious discharge of its various duties; though they may, at the same time, be quite unable to give a connected view of its doctrines. But it is necessary that some should be able to do this; and we know no subject that requires a greater variety of talent, extent of information, and application of judgment, than the successful illustration of the doctrines and duties of Christianity.

In contemplating any perplexing dispensation, the mind of the uninstructed can only go the length of saying, *such is the will of heaven:* this is sufficient to produce acquiescence, and to silence any rising scruples in a mind not addicted to investigation. But in order to produce satisfaction and delight, the point in question must be reduced to some general principle, and shown to be perfectly consistent with the wisdom and goodness of God as recognised in other instances. The history of Job tends to illustrate these observations. He submitted, at first, because he knew that his sufferings were appointed by God; and even when he contended that they were unmerited on his part, he insisted no less on the prerogative of the Almighty to do what he pleased. But when God condescended to reason with him, he saw a different or rather an additional ground of submission, and acknowledged not only the sovereignty of God, but the wisdom and goodness which governed all his dispensations.

But even those who exclaim most against creeds and systems *must* form to themselves a system of some kind or other, out of the Sacred Scriptures; for the mind must endeavour to obtain a connected view of the doctrinal and practical information contained in them, and this is all that a system of divinity attempts; this is what every preacher of Christianity endeavours to exhibit in his discourses, and it would be just as reasonable to object to his oral instructions, as to a written record of his opinions, respecting the doctrines and duties enforced or inferred in the Gospel.

Were it not for the ignorance which obscures the reason, and the prejudices which pervert the judgment, and the doubts and anxieties which must be connected with a subject of such immense importance as the religious hopes of men, the perusal of the Scriptures would be sufficient both for instruction and consolation. But where there are so many sources of error originating in the passions which agitate the human mind, and when the subject is of such vast importance that the heart is afraid to trust its own surmises, it must at least appear a friendly office to point out the leading doctrines of Scripture, and to show their bearings on the duties and the hopes of men. The great head of the church saw it necessary to appoint apostles, evangelists and teachers for this purpose, and this is the object which every one ought to have in view in illustrating the word of God. There is also another point of view in which creeds, confessions, or systems, (or by whatever other name they may be called), are rendered necessary, viz. to obviate the misrepresentations of enemies, and to rescue the Gospel from the opprobrium brought upon it by the misconduct or absurdities of sects or individuals professing Christianity. This is the origin of the apologies of the early fathers, which are neither more nor less than expositions of the Christian creed, as it affects the opinions and practice of those who receive it. The grossest falsehoods respecting their tenets were propagated by their heathen adversaries, and, what was worse, the greatest discredit was brought on Christianity by numerous heretics who professed to adopt it. In these circumstances, the genuine followers of Christ found it necessary to give a detailed account of their faith and of the duties which resulted from it: and the same thing will be necessary so long as the enemies of Christianity shall seek to misrepresent it, or wicked men endeavour to make its sacred name a cloak for licentiousness.

Such being the character, and such the contents of the sacred volume, we are naturally led to inquire into its origin and authority. On this point the declaration of the apostle is perfectly explicit; he tells us expressly that *all Scripture is given by inspiration of God;* and it is absolutely necessary that it should be so from the circumstances of the case. We have seen that a revelation from heaven was necessary; and we have ample proof that such a revelation has actually been given. Assuming at present that this is the case, we would observe that it was absolutely necessary that this revelation should be recorded, and that the record containing it should be preserved from corruption by the superintending influence of the Spirit of God. What would it avail us to know that God had revealed his will to men, and unfolded prospects most interesting to our nature, had we not the assurance that we possess an authentic record of this communication, and an accurate account of its meaning and import? Had it been left to float down the uncertain channel of tradition, or to receive such colouring as the imagination or caprice of men might think proper to bestow upon it, it would soon have been perverted in its meaning, or abused in its application.

But it may be asked, were not ordinary means sufficient for this purpose? Were not men of honest and upright minds able to record the facts which they had seen, and the doctrines which they had heard? In answer to this, we must observe that the facts recorded in Scripture resemble the facts contained in any other history, except in regard to the explanation which is given of their cause, their tendency, and the end they are designed to accomplish in the economy of divine providence. This is what no man without the gift of inspiration can unfold.

In ordinary histories we must rest satisfied with such information as we can find: and generally speaking, the *facts* are accurately reported, whilst the whole train of reasoning on their causes and consequences (which constitutes the beauty and utility of history) is often entirely fallacious: and the most interesting and best written histories are often the least authentic; because the writers, in order to conceal their ignorance of the primary and final causes of events, substitute in the place of knowledge ingenious conjectures, or the romantic dreams of their own imaginations. In cases of this kind, however, error is, comparatively speaking, of little importance. The reasons and motives of actions, assigned by ordinary writers may, or may not be true, without materially affecting the comfort of society; and even a fictitious narrative, if drawn from the general storehouse of human nature, may be both amusing and instructive. But we cannot endure the idea of fiction or uncertainty, where our eternal interests are concerned; and as the reasonings and inferences deduced from the facts recorded in Scripture form the very essence of our religion, being the virtual enunciations of the doctrines on which we build our faith and our hopes, we never can be satisfied till we are assured that these reasonings and inferences rest on the basis of infallible truth. More than human wisdom, then, is necessary to give the right interpretation of Scripture facts, and to deduce from them their legitimate consequences; for we never could build our hopes with confidence, on doctrines which derive their authority merely from the opinions and interpretations of fallible men. It is as necessary to know that the record containing a divine revelation is uncorrupted and infallible in its formation, as it is to know that a revelation came originally from God; and we might as well be without a revelation altogether, as have one embodied in a record, on whose accuracy we cannot depend. In short, none but those who were inspired to announce divine truths were qualified to record them; and if we are satisfied that the prophets, evangelists and hagiographers, had communications from heaven, we may be certain that their writings, whose genuineness and authenticity are most fully established, convey an accurate representation of their heaven-inspired impressions to mankind.

These writings contain strong internal evidence that they proceed from no ordinary source. We see what distortion is given to Scripture facts, and what havoc is made of Scripture doctrines by those, in modern times, who interpret the Word of God according to their own fancy. And why does not the same variety of opinion prevail among the writers in the sacred volume? They were men of like passions with us; in matters of inferior importance, they did not always agree in opinion; nay, they sometimes represent the facts of Scripture in very different aspects; yet, with all this, there is not the slightest variation as to Scripture doctrine. Now this is exactly the reverse of what occurs in the case of ordinary writers, when several of them are recording the same event. They in general agree as to the statement of facts, whilst there is scarcely any such thing as agreement, with respect to their causes, or the inferences which are to be deduced from them.

We are not to suppose that the sacred writers did not exercise their own judgment in commenting on the events which they record, though there is such a striking agreement in their sentiments. But we have reason to conclude, that their understandings were enlightened, their imaginations chastened, and their minds purified by a superintending influence, when we see them always led to the same interpretation and the same conclusion, though the facts were presented to their senses, and are recorded in their writings in very different points of view. These facts, indeed, sometimes appear so inconsistent with each other, that, to save the credit of Scripture, in general, some have chosen to abandon the idea of its *complete* inspiration. This would be both a dangerous and unnecessary concession. For, first of all, this apparent discrepancy in the statement of facts, is the clearest proof that there was no collusion among the writers. Had they formed a design to impose on the world, nothing could have been more easy than to have preserved a perfect consistency as to the detail of facts. They were not cross-examined in a court of justice, and betrayed into contradictory statements: they wrote down deliberate accounts of what they had heard and seen, which they could easily have made to agree with each other, but which were evidently sent into the world without any communication, and without any concern, whether they confirmed or contradicted preceding statements. And, in the next place, the inconsistency is not real, but apparent; and in every case, where it has been supposed to exist, it will be found to originate only in our own ignorance. Particulars different, but not inconsistent; varied, but not contradictory, are presented to our view; and we are thus furnished with an addition of knowledge, not with an opposition of facts.

If we descend from general reasoning, and consider the particular parts of Scripture, we shall find the most decided evidence of their inspiration. Take, for instance, the books of Moses, and consider the nature of their contents. He established laws and ordinances of a most singular nature, totally different, in many respects, from any thing that had ever been seen in the world. That the whole nation should rest from labour every seventh day: that the whole land should lie uncultivated every seventh year, were regulations so contrary to common practice, and to general interest, that no man in his senses would have thought of enjoining them, without the certainty of being supported by divine authority. He does not recommend them by powerful eloquence, nor attempt to defend them as measures of policy: the only argument that he condescends to use, is, *thus saith the Lord;* and he appeals not to the reason, but to the senses of the Israelites, for the confirmation of his statements; directing them to the miraculous displays of power, by which God seconded all the institutions enjoined by his servant.

But we have the most decided evidence, that Moses not only acted but wrote by inspiration, or by the immediate direction of heaven. Where, for instance, did he find those sublime doctrines respecting the unity of God, and the purity of his worship, which we every where perceive in his writings? Not in Egypt where he was brought up; for though he was learned in all the wisdom of the Epyptians, they had no substantial knowledge on these subjects which they could impart. They had made some progress in physical science; and from their knowledge of the properties of matter, they were enabled to exhibit a number of tricks which astonished the multitude. But of all people on the face of the earth, they were the most absurd and preposterous in their religious creed; and Egypt, which has been called the cradle of the arts and sciences, may with equal propriety be styled the nursery of superstition and idolatry. Nor was there any other country from which the Jewish legislator could borrow his doctrines concerning the divine nature and government. His writings on these subjects stand *unique* amidst all the monuments of antiquity; and the very existence of such a system of doctrine and worship among the Jews at such an early period, is a proof that it must have been from heaven; for nothing like it had ever before been seen on earth; nor did the human mind, amidst its multifarious speculations, ever afterwards stumble on the same doctrines. They were so foreign to its views and prejudices, that it could not adopt them by imitation; and in attempting to describe them, uniformly misrepresented and debased them.*

After the books of Moses come the historical books, and no part of Scripture has more decided claims to inspiration, nor is there any part with regard to which that claim is more decidedly asserted. The writers announce, without the slightest hesitation, the mind of God in regard to the transactions which they record; and they unfold, without the smallest scruple, or doubt, the motives which actuated the minds of the principal actors. They do not seek the praise of ingenuity for shrewd or profound speculations as to the great moving causes of events; they never reason in order to show what is the most probable view of the subject, nor do they labour to win assent to their statements: they profess to record nothing but what God has communicated, and having given such information, their commission ends. Nothing has ever been found to contradict, but every thing to confirm their statements, which may be regarded as commentaries on the law of God to prevent its misinterpretation and misapplication by the ignorance and prejudices of men.

Next in order come the books which authors have called *Hagiographa*, or holy writings. These

* Witness the misrepresentation of Strabo, (lib. 16.) who, having informed us truly that Moses forbade to make images of the Deity, tells us farther, that he taught that the heavens, the world, and the nature of things, were themselves the only true God, ειη γαρ ἓν τυτο μονος θεος το περιεχον ημας ἅπαντας και γην και θαλατταν ὃ καλυμεν υρανον και κοσμον και την των οντων φυσιν. Juvenal falls into the same mistake, when he says of the Jews, "Nil præter nubes et cæli numen adorant." Sat. xiv. 97.

are Job, Psalms, Proverbs, Ecclesiastes, and the Song of Solomon. In the book of Job, much light is cast upon the dispensations of heaven, and many doubts and objections which might naturally rise in the mind are obviated. We are taught patience and resignation, from the consideration that we know not the end which God has in view by the visitations which affect us; but we are assured that all things are guided by unerring wisdom, and unchangeable goodness. These are the lessons inculcated in the book of Job, and they are the most important that can be learned by man.

The Psalms are a collection of sacred songs and hymns by a variety of authors, but by far the greater part by David, insomuch that the collection generally bears his name. They form a valuable record of devotional feeling; all the workings of the human heart are here displayed; the doubts and the fears, the joys and the transports which successively agitate the mind are here pourtrayed, and it will always find something here, to suit its varied shades of feeling, from the first aspirations after holiness, checked by ignorance, and inherent unbelief, to the complete triumph of faith, and assurance of hope. In short, the Psalms are the safest manual of devotion, and the most authentic, perhaps the only authentic journal of the thoughts and emotions which are excited in the mind under the varied dispensations of heaven.

The Proverbs contain a great variety of most excellent maxims of moral wisdom; and such a collection forming part of the canon of sacred Scripture, conveys to us this important truth, that the service of God ought to be combined with the soundest wisdom and discretion. The Proverbs of Solomon correspond so exactly with the maxims which enlarged experience sanctions, that some have said there was no need for inspiration to produce a collection of practical rules, so consistent with utility and common sense. But surely it is useful to know that such rules have the sanction of the Spirit of God; and that the headlong folly which cloaks its extravagances under the garb of religion is altogether alien from the Spirit of truth.

The book of Ecclesiastes contains a history of the experiments made by a man of great power and wisdom to secure happiness, by bringing into operation all the resources which wealth, power, and wisdom could supply. The result of his experience was, that "All is vanity and vexation of spirit," and that "To fear God and keep his commandments is the whole duty of man!" The first conclusion has been reached by many who had no pretensions to the wisdom of Solomon, whilst they have missed the latter and most profitable result of his experience.

The Song of Solomon has been more the subject of cavil, than any other part of sacred Scripture. From the absence of the name of God in it, and from the style of the imagery, which is luxurious and amatory, some have argued that it cannot be an inspired composition. This is a hasty, and we are persuaded an unfounded conclusion. It has, from the earliest ages, been considered as forming a part of the canon of Scripture. The Jews always regarded it in this light, and it never would have descended to our times, had it not been protected by its sacred character. Solomon was a very voluminous writer; "His songs were a thousand and five; and he spake of trees from the cedar tree that is in Lebanon, even unto the hyssop that springeth out of the wall; he spake also of beasts, and of fowl, and of creeping things, and of fishes." 1 Kings iv. 32. But none of his productions are preserved, but such as were of a sacred character. The style and imagery of the composition in question, however opposite to European taste, and to the notions of propriety adopted in modern times, form no objection, if they can be shown to be applied in Scripture to subjects confessedly spiritual and religious. This may be easily done: the forty-fifth Psalm presents the same imagery applied in a religious sense, and may be regarded as a pretty accurate abridgment of the Song of Solomon. And this composition seems to be referred to in the New Testament, when the apostle says, "I am jealous over you with a godly jealousy; for I have espoused you to one husband, that I may present you as a chaste virgin unto Christ." 2 Cor. xi. 2.

The writings of the prophets carry in their face the evidence of divine inspiration. We have only to show that prophecies predicting future events existed, and that the events foretold actually came to pass, to satisfy any rational mind that the information of the prophet must have been from heaven. Such facts as these occur not merely in a few instances, so as to induce a suspicion of conjecture, and of casual fulfilment. All the great events which have influenced the affairs of men are written *beforehand* in the records of prophecy; and the historian who comes afterwards, has only to fill up the great outline which had been previously drawn by the inspired prophet.

The writers of the New Testament Scriptures have no less decided claims to inspiration. Their Master assured them that the Spirit should be given to bring all things to their remembrance, and they did not write till this promise was fulfilled by the visible descent of the Holy Ghost on the day of pentecost. Friends and enemies have received the books of the New Testament as the undoubted writings of the authors whose names they bear; and when we consider the circumstances in which these authors were placed, without education or the usual opportunities of knowledge; and when, notwithstanding these disadvantages, we see them inculcating doctrines and precepts which leave far behind them all the instructions of human wisdom, it is impossible not to conclude that they wrote under the inspiration of heaven.

The Scriptures being the word of God, must naturally be regarded as the grand depositories of all religious knowledge: they teach us the doctrines which we are called upon to believe, the duties which we are to practise, and the hopes which we are warranted to entertain: they explain the nature and character of God, but they contain no laboured arguments to prove his existence. It would have been a mockery and misapplication of reason to have adduced metaphysical arguments to prove what was demonstrated to the senses. They who believe the facts of Scripture, which are so many records of the being and power of God, cannot possibly doubt his existence; much less could those who were the eye and ear witnesses of those extraordinary transactions. Did we find a single argument in the writings of Moses to prove the existence of God, beyond those drawn from the miracles which the Israelites saw, it would justly bring suspicion on the whole record; for what could be the use of reasoning where conviction was applied immediately to the senses, and palpable demonstrations daily afforded of the presence and power of God? In these circumstances, the absence of inductive reasoning is exactly what might have been expected, and strongly confirms the authenticity of the record, and the genuineness of the facts which it contains.

Though we are now placed in different circumstances, yet it cannot be necessary to spend much time in proving the existence of God: we are almost as sure of it as we are of our own; at least we may be as sure of it as we are of the existence of a rational soul in our fellow men. All that we see of man is a corporeal structure and material organs, composed of the same elements as external nature. Consciousness and feeling may give an individual a conviction that there is something in his constitution of a higher order and character. He can reason and plan, and manifest his feelings in a great variety of ways: hence he infers the existence of a principle within him, different from the matter of which his body is composed; and when he sees the same manifestations in the case of others, he concludes that there is the same power of feeling, reasoning, and executing. But the soul, which is the grand agent in all these transactions, he cannot see: he infers its existence only from the effects which it produces. Now, as we cannot possibly mistake the visible universe for the work of man, we are compelled, from the appearances of design, and the wise adaptation of means to ends, to ascribe it to a being possessed of power, intelligence, and goodness, inconceivably exalted above the faculties and resources of man. Thus, we see God as visibly in his works, as we discover the existence of an intelligent spirit in man from its various manifestations.

We pass over the various arguments, metaphysical and inductional, which have been adduced to prove the existence of God, and proceed to consider the information which the Scriptures have given us respecting his nature, character, and attributes. They uniformly, and in opposition to all the ancient nations, assert the existence of one God: and this unity of the divine nature is demonstrated by the universality of divine providence, as manifested in the fate of the different nations whose destinies are pronounced in Scripture, long before the prediction was verified by the event. This proves that one mind had the knowledge and disposal of the fortunes of the kingdoms of this world. Philosophy proclaims the same important truth, and shows such a unity of design and harmony of purpose, reigning throughout all the arrangements of the material world, as proclaim them all to be under the direction of *One* superintending mind. The same laws which regulate the motions of the heavenly bodies, operate on the surface of this earth, and show the heavens and the earth to be under one and the same governor.

The perfections of God in which we may share, or as they have been called his communicable perfections, are wisdom, power, holiness, justice, goodness and truth. His incommunicable, or his essential attributes, are his eternity, self-existence, immutability, omnipresence, &c. These may be called the attributes, or characters of his perfections, to which we can conceive no limits or bounds. In these attributes we cannot participate: they constitute the essential nature of Deity, and without them God would not be an object of religious homage and adoration. It might be highly interesting to contemplate a being just, and good, and wise, and holy; but no religious homage could be due to such a being, did his perfections admit of any limitations, or were he not infinitely removed above all chance, and above all change, and not affectable by any of the vicissitudes which attach to all created things.

The providence of God, or his care over the world which he has made, is proved by the existing state of the visible universe. To suppose that the world and its inhabitants can exist without the immediate care and superintendence of God, would be to suppose them independent of his power: but if we may venture to assign limits to the power of God, we would say that it is limited by this, that he cannot do any thing that is unworthy of himself, nor make any thing independent of his power. To create any being, or any thing absolutely independent, would be to impart his own incommunicable perfections; and this we may safely pronounce to be impossible: it exceeds even the power of omnipotence to make any thing as great as the uncreated Deity. In every thing, then, that lives or grows, or exists, we see not a natural efficiency, but a divine energy; even in the rudest mass of inanimate matter, we see a divine power; because it is held together, and retains its form and qualities, only in consequence of those laws which God has established, and which preserve their force, only because his will keeps them in operation.

Thus far, all that is taught in Scripture respecting the unity of God, and his universal providence, is confirmed by every argument of enlightened reason. In the government of the world, we see none of that discordance which marks divided empire; even those things which, at first sight, might appear as irregularities in the plan, are found, on closer inspection, to be essential parts of it, and to bear unequivocal testimony to the unity and overruling providence of God. But the Scriptures give us some information respecting the mode in which the divine nature subsists, which it does not appear that reason could ever have suggested. We allude to the doctrine of the Trinity, of which, we are inclined to think, no vestige can be found, except among those who have received it, directly or indirectly from the sacred Scriptures.

It is true that something resembling this doctrine is to be found in the mythology of some of the gentile nations. It seems to be acknowledged in the theology of Hindostan, in the characters of Brama, Vishnu, and Seva, whose image, in the most ancient representations, appears as a human body with three heads. A species of Trinity also was taught in the schools both of Pythagoras and Plato, and is largely insisted on by the followers of the latter. The doctrine of Plato on this subject is, that there are three principles in the Deity, goodness, intelligence, and vitality; and that these three, though distinct, are more *one* than any thing in nature of which unity may be predicated; as no one of them can be supposed without the other two. When Christianity began to prevail in the world, many Platonists embraced it; and when the doctrine of the Trinity began to be impugned, they attempted to defend it as a docrine of reason, by affirming that it was taught in the philosophy of Plato: whilst the unconverted Platonists maintained that the Christians had borrowed the doctrine from the Grecian philosopher. Had the language of Plato on this subject been as clear as that of his followers, we should have concluded that he had derived his knowledge from the traditions current among the Jews, and which had passed from them to other nations of the east. But, after all the labours of Cudworth, we cannot perceive that Plato teaches any thing resembling the Christian Trinity. Something more like to it appears in the doctrines of the Pythagoreans, as represented by Simplicius, who tells us that one of their authors describes the *First One* as being above every existing substance; the *Second One* as represented by Ideas, or Intelligible Species; and the *Third One*, as Vital or Psychical (ψυχικον) and partaking of the nature of both the former.*

But it is evident that this is a philosophical conceit, founded on opinions which had long been prevalent. In the esoteric doctrines of several of the ancient philosophers, the divine nature was considered as one and indivisible, immovable and unaffectable: at the same time they considered God as diffused through all things, and all things as partaking of the nature of God: hence they conceived his nature to exist both in the intelligible species, by which they supposed all things to be apprehended by the understanding, and also in the visible system of things which are the objects of our external senses. This gave a kind of triplicity of modification to the divine nature, which was nevertheless considered to be, in itself, simple and one.

This doctrine, or some notions of a similar kind, tended strongly to produce a perversion of the Christian doctrine of the Trinity, when the Platonizing philosophers began to embrace the Christian faith, and the errors arising from this source have continued to infect the faith of many professing Christians down to the present day. To give an enumeration of the heresies and conceits which have been entertained on this subject would only be to exhibit the weakness or the presumption of the human mind. All that is proposed is to give the history of the doctrine of the Christian Trinity; and to state the arguments from Scripture by which it is supported.

There is one thing connected with this subject which cannot but strike every person as remarkable. The Trinity is no where announced in the New Testament as a new doctrine, neither is it any where formally taught: it is taken for granted, or stated as a matter of course, and referred to rather as a thing that was well known, than as a doctrine which had been unheard of before.

Was this doctrine, then, known to the Jews under the Old Testament dispensation? It certainly is not expressly taught in the sacred writings, anterior to the Christian revelation; but it is pretty evident that the Jews must have had some notion of plurality as connected with the Divine nature. This is implied in the phraseology of Scripture, as when the Creator says, "Let *us* make man," and "the man is become as one of *us*." It ought also to be observed that the word *Aleim* or *Elohim*, which is translated God, is a plural noun, but is nevertheless generally joined by Moses, in his account of the creation, with a verb in the singular, to indicate, as is supposed, his knowledge of the mysterious nature of the Godhead.

The influence of the Spirit of God is often mentioned in the Old Testament Scriptures, and personal qualities are ascribed to it. The Spirit of God rested on the seventy elders and they prophesied, Num. xi. 26. Isaiah says, "The Lord God and his Spirit hath sent me." xlviii. 16. Numberless passages might be quoted to the same purpose, in which qualities and operations are distinctly ascribed to the Spirit of God as a person, and not as an energy of the Divine nature. And, in whatever way they came by their belief, it is no less certain that the Jews, previously to the time of our Saviour, ascribed a distinct personality to the Word of God. Thus in the apocryphal book of Wisdom, which is unquestionably ancient, and supposed to be the production of some Hellenistic Jew, who lived before the time of our Saviour, we find the following passage: "Thine Almighty Word leaped down from heaven, out of the royal throne, as a fierce man of war into the midst of a land of destruction." xviii. 15.

But the most decided evidence on this subject is to be found in the Targums of Jonathan and Onkelos; the one being a commentary on the prophets; the other on the books of Moses. They are both written in Chaldee; that of Jonathan was written, according to Calmet, about thirty years before Christ: that of Onkelos not long after it, and they are both, till this day, held in the highest estimation among the Jews. From these commentaries, then, on the Old Testament Scriptures, we learn in what sense particular passages were understood by the Jews. Onkelos says on Exodus xix. 3, that Moses "went

* Ουτος γαρ κατα τους Πυθαγορειους το μεν Πρωτον Ἑν υπερ το ον και πασαν ουσιαν αποφαινεται το δε Δευτερον Ἑν, όπερ εστι το οντως ον και νοητον, τα ειδη φησι ειναι το δε Τριτον, οπερ εστι ψυχικον, μετεχειν του Ἑνος και των Ειδων. Apud Cudworth, chap. IV.

up to meet the *Word* of the Lord," and again, in the 17th verse, he says, "Moses brought the people out of the camp to meet the *Word* of the Lord."* The Targum of Jonathan is equally explicit: on Deut. v. 5, he says, "Moses stood between them and the *Word* of the Lord:" and in the 23d verse, he says, "After ye had heard the voice of the *Word* out of the midst of the darkness," &c. which shows that the Word is to be understood in a personal sense, as distinguished from the voice of God.†

The same phraseology prevails throughout the work of Philo Judæus, *De Mundi Opificio*, in which he almost everywhere speaks of the Word of God as a person, and ascribes to him the creation of the world.

From these facts, then, we may reasonably conclude that St. John was stating nothing but the received doctrine among his countrymen, when he said, "In the beginning was the Word, and the Word was with God, and the Word was God; the same was in the beginning with God: all things were made by him, and without him was not any thing made that was made." No Jew of those times could possibly object to this doctrine. Nay more, the Jews positively expected the visible manifestation of this Word in the person of their Messiah. They would not have been offended at the doctrine that "the Word was made flesh and dwelt among us," had not Jesus of Nazareth, of whom this was predicted, appeared in a character, and in circumstances so very different from what they expected. This is apparent from the gospel history. When our Lord was accused before the Jewish council, the high priest said to him, "I adjure thee by the living God, that thou tell us, whether thou be the Christ, the Son of God." From this it is evident, that they expected the manifestation of "the Christ the Son of God." Our Lord answered the question indirectly by saying, "hereafter shall ye see the Son of Man sitting on the right hand of power, and coming in the clouds of heaven." This is an evident allusion to Dan. vii. 13, 14, where it is said, "And, behold, one like the Son of Man, came with the clouds of heaven, and came to the Ancient of Days, and there was given him dominion and glory and a kingdom," &c. On hearing our Lord apply these words to himself, "the high priest rent his clothes, saying, he hath spoken blasphemy, what farther need have we of witnesses?" Matt. xxvi. 64, 65. This incident proves two things; first, that the Jews considered the passage in Daniel, which our Lord applied to himself, as applicable to the Messiah; and, secondly, that though he is there called the "Son of Man," they nevertheless admitted that he was to be, in reality, "the Son of God," and to have a kingdom which should never be destroyed. This was the character which they recognised as belonging to the Messiah; and our Lord was judged guilty of blasphemy because he asserted that the words of the prophet were fulfilled in him.

A curious commentary on the vision of Daniel has recently been furnished us from the book of Enoch,‡ lately translated from the Ethiopic, by Bishop Lawrence. The work is evidently apocryphal, and was considered as such by the early Fathers; it is, however, unquestionably ancient: and there seems not the smallest doubt that it is a fair translation of the work quoted by Jude. We refer to it, as we have done to the other apocryphal writings, and to the writings of Philo Judæus, merely to illustrate the opinion of the Jews respecting a plurality of subsistences in the divine nature. That such an opinion prevailed among them is very clear from the commentary which the author of this book makes on the vision of Daniel. He has availed himself of the prominent facts and prophesies of the Old Testament Scriptures, and has represented them as seen in vision by Enoch, and related by him to his son Methuselah. The vision of Daniel, of course, was not to be overlooked, as it is evidently prophetic of great and remarkable events: and this author shows the interpretation which he, and, we may conclude, the thinking part of the Jews, (among whom, it is evident, his book was received as a work of authority,) assigned to the most remarkable circumstances in this prophetic vision. "There I beheld the Ancient of Days, whose head was like white wool, and with him another whose countenance resembled that of man. His countenance was full of grace like one of the holy angels. Then I inquired of one of the angels, who went with me, and who showed me every secret thing concerning this Son of Man—who he was—whence he was—and why he accompanied the Ancient of Days." Ch. xlvi. 1. In the remainder of this chapter, and the whole of the next, he continues to celebrate the praises, and proclaim the exploits of the Son of Man. In the 48th chapter the subject is continued, and in the 2d and 3d verses we find these remarkable words. "In that hour was this Son of Man invoked before the Lord of Spirits, and his name in the presence of the Ancient of Days; before the sun and the signs were created, before the stars of heaven were formed, his name was invoked in the presence of the Lord of Spi-

* See the Targum of Onkelos in Walton's Polyglot. Tom. i. p. 37.

† See particularly Allix's Judg. of the Jewish Church, for all the passages indicating plurality in the Godhead.

‡ Three copies of this work were brought from Abyssinia, by Bruce. He retained one to himself, and deposited one in the library of the King of France, and the other in the Bodleian Library at Oxford. No translation of the work into any modern European language has appeared till Bishop Lawrence published his English translation in 1821. A large fragment in Greek from the chronographia of Georgius Syncellus, was published by Scaliger. The work from which St. Jude quoted was extant in the second century. For Irenæus, who wrote in that century, distinctly alludes to events recorded in it and no where else, and Tertullian translates a long quotation from it. The Greek copy of the work, a translation probably from the Hebrew or Chaldee, seems irretrievably lost. Ao idea, however, prevailed in the beginning of the seventeenth century, that a translation of it existed in Ethiopia. But all attempts to procure a copy were unsuccessful, till the three above mentioned were brought into Europe by our countryman Bruce, the prince of modern travellers, whether we consider his courage, his prudence, or the intelligenco with which he conducted his researches. His copies contain the passages quoted by Syncellus and the Fathers, as well as that quoted by Jude; and there can be little doubt of their being fair translations of the original.

rits:" and at the 5th verse, he says, "therefore the elect and the concealed one existed in his presence before the world was created, and for ever." These passages are valuable as recorded testimonies of the belief of the Jews in the pre-existence and Deity of the person designated by Daniel, the Son of Man.

Nor is this all, in the 60th chapter a distinct allusion is made to a Trinity of persons in the Godhead. "He (the Lord of Spirits) shall call to every power of the heavens, and to all the holy above, and to the power of God. The Cherubim, the Seraphim, and the Ophanim, all the angels of power, and all the angels of the Lord, namely of the elect one, and of the other power, who upon earth were over the water on that day, shall raise their united voice," &c.

We see not the slightest reason for questioning the antiquity of this book, or the integrity of the text, on account of these obvious allusions to the Son and the Spirit. On the contrary, whatever may be thought of the genuineness and authenticity of the text in 1 John v. 7. we are persuaded that it states nothing but the common creed of the Jews at the time it was written, and that the most intelligent among them would have subscribed to the doctrine that "there are three that bear record in heaven, the Father, the Word, and the Spirit, and these three are one."

We can easily conceive that this text is an interpolation, since it is not found in some of the most ancient copies of the New Testament, and is not quoted by the ancient Fathers in their disputes with those who denied the doctrine of the Trinity.* But if it is an interpolation, (which, after all that has been written, we do not think sufficiently proved,) it is nevertheless an accurate statement of the generally received doctrine among the Jews. How they arrived at the knowledge of a doctrine not clearly taught in the law and the prophets, cannot be a question of much difficulty, when we consider that they had so many inspired teachers among them, who might deliver much in their instructions which they did not commit to writing, and who in illustrating the word of God, might explain the meaning of those passages in which the doctrine was implied, though it might be overlooked by an ordinary reader. It was, no doubt, in this way that the resurrection of the body, which is nowhere clearly taught in the Old Testament, was nevertheless universally received among the Jews, except by the sect of the Sadducees, long before it was so clearly revealed and demonstrated in the New Testament.

And it will not be denied that there was an obvious propriety in preparing the minds of men by previous instruction for the reception of a doctrine so highly mysterious and important as that of the Trinity. In consequence of the prevailing opinions on this subject, the Apostle Peter, when he witnessed the power and wisdom of his Master, had no hesitation in declaring, "we believe and are sure that thou art the Christ, the Son of the living God;" hence, too, our Lord had no occasion to enter into any explanation when he enjoined his disciples to "go and teach all nations, baptising them in the name of the Father, and the Son, and the Holy Ghost;" and from the same circumstance, Mary expressed no surprise when she was told that the Holy Ghost should come upon her. She was immediately satisfied, having heard before of the existence of such an agent.†

Having attempted to give a short history of the doctrine of the Trinity, it now only remains to adduce some texts from the New Testament in which the doctrine is either clearly stated, or obviously implied.

And surely nothing can be more explicit than the passage just quoted respecting the institution of baptism. This rite, as a token of regeneration, and as a sign of our being admitted to spiritual privileges and blessings, can only be administered in the name of God; for he alone can offer and ensure these blessings to mankind. But it is here expressly ordained to be administered in the name of the Father, of the Son, and of the Holy Ghost, to each of whom personal qualities are ascribed throughout the New Testament; when, therefore, we see all the three associated in a work that can belong only to God, the unavoidable inference is, that there are three persons in one Godhead. Indeed it seems to be as impossible to mistake the meaning, as it is to explain away the force of this plain text. The words of the Apostle, at the conclusion of the Second Epistle to the Corinthians are equally clear, and the inference deducible from them equally incontrovertible,—"the grace of the Lord Jesus Christ, the love of God, and the communion of the Holy Ghost be with you all." As if it had been to obviate the opinion which afterwards sprung up, that the Son and Holy Ghost are only particular manifestations or energies of the same person; the Son is here mentioned first, to show his inherent Godhead, and claim to religious adoration; and that there might be no possibility of confounding the three *subsistences* or *hypostases* of the Godhead as mere modifications of the same divine person, all the three are, on one occasion, repre-

* Without entering at all into the controversy respecting this text, it may be sufficient to give the following general statement of the grounds on which it rests. The verse has not, as yet, been found in any very ancient Greek manuscript of the New Testament; it is said only to be found in one copy of comparatively modern date, being supposed to be of the fifteenth century. Hence it is inferred that the verse is wanting in the copies from which the most ancient Greek MSS. have been transcribed, up to the autograph of St. John On the other hand, the verse is found in the most ancient copies of the Latin Vulgate, which the supporters of the text maintain to be a correct translation from a genuine Greek original. But the strongest evidence in favour of the text occurs in the writings of Cyprian, who died in 258, who seems directly to quote it; for he says in his treatise *De unitate ecclesiæ*, "Dixit Dominus, Ego et Pater unum sumus; et iterum, de Patre et Filio et Spiritu Sancto scriptum est, *Et hi tres unum sunt.*" This seems to imply that the text was found in Scripture, (for he says, *scriptum est*,) in the time of this father.

† Those who wish to prosecute this view of the subject farther, will find ample information in Bishop Bull's work on the Trinity, Cudworth's Intell. Syst. Book I. Ch. 4. Horsley's Letters to Priestley, Maurice's Indian Antiquities, vol. iv. passim, and Alix's Judgment of the Jewish church against the Unitarians.

sented at once, under sensible manifestations, and in very distinct characters and circumstances. "It came to pass that Jesus being baptized and praying, the heaven was opened, and the Holy Ghost descended in a bodily shape like a dove upon him, and a voice came from heaven which said, "Thou art my beloved Son, in thee I am well pleased." Luke iii. 21. Here the voice of God was heard from heaven, the Holy Ghost was seen descending, and lighting on him, who was pronounced to be the beloved Son of God. Again the Son and the Spirit are mentioned as distinct from the Father; and as distinct, too, from each other in their persons, and in their operations in bringing men to God. "Such were some of you; but ye are washed, but ye are sanctified, but ye are justified in the name of our Lord Jesus, and by the *Spirit* of our God." 1 Cor. vi. 11.

We shall have occasion afterwards, to notice particularly the divinity of the Son; and, therefore, we shall close this discussion on the Trinity with a few texts, tending to prove the divinity and distinct personality of the Holy Spirit. His Divinity is proved by the reproof of the Apostle Peter to Ananias, Acts v. 3, 4. "Why hath Satan filled thy heart to lie to the Holy Ghost? Thou hast not lied unto men. but unto God." And his distinct personality is proved by our Lord's words, Matt. xii. 31, 32. "All manner of sin and blasphemy shall be forgiven unto men; and whosoever speaketh against the Holy Ghost, it shall not be forgiven him, neither in this world, neither in the world to come."

If language has a meaning, and if the sacred records can be depended on for settling a point of faith. we must consider this passage as perfectly conclusive, as to the divinity and distinct personality of the Holy Spirit. He is God because men may be guilty of blasphemy against him, which cannot be said of any created being,—blasphemy can only be committed against God; and he is distinct from the Father and the Son, inasmuch as blasphemy against him is unpardonable, which is not the case when committed against the Father or the Son.

We do not reckon it necessary to proceed farther in adducing Scripture proofs of this doctrine. A vast number of texts equally applicable might be quoted, and the whole tenor of the New Testament Scriptures is in exact conformity with the obvious meaning of those passages which have been adduced. The opponents of this doctrine make a very unreasonable demand upon us, and require us to bring it down to the level of their understanding. They who make such a demand should forego all discussion respecting the nature of God, the principles of human conduct, and the ordinary phenomena of nature: for on all these subjects they must soon be involved in inextricable mystery. What, for instance, can we know of that God whose being and attributes we can demonstrate? He is self-existent, eternal, without beginning and without end, omniscient, omnipresent, illimitable. Can we comprehend the nature of a being possessed of such attributes? No: his nature is unsearchable, his ways are past finding out. But it may be said that this subject only transcends the power of our reason, while the doctrine of the Trinity contradicts its intimations. This is not the case. We are compelled to believe things as extraordinary and as incomprehensible by our faculties. The soul and the body make one person, yet we believe them to be totally different from each other in substance, nature, and qualities. Various faculties, how many we cannot tell, compose one mind, though they are very opposite to each other in their operations. Indeed, we are probably not acquainted with a single simple substance in nature. The air which we breathe is a triple compound; the water which gives fertility to the earth is composed of, at least, two ingredients; and the light, which used to be considered as the purest of all elements, is found to be a very complex substance.

These things are adduced not as proofs, but as illustrations; and they are brought forward in this view, to obviate objections, rather than to produce belief. The doctrine of the Trinity depends on testimony, rather than on reasoning; except in so far as reasoning is employed to establish the testimony by which it is supported: it rests on the same foundation with the general plan of revelation, and they must stand or fall together. But as all the objections to the doctrine are professedly founded on reason, these objections are done away when reason can point out analogous facts to meet the arguments which have been supposed to invalidate the doctrine. The eternal generation of the Son, for instance, has been objected to as not only incomprehensible, but impossible. To this Jortin (who is not over orthodox on the subject of the Trinity,) replies, that to deny the possibility of this would be to deny that God had the power of working from all eternity. Again it is said, how can the Son and Spirit proceed from the Father and yet be equally eternal with him? This has been answered by Pearson long ago, by an illustration drawn from the visible sun: for were we to suppose this luminary to be eternal, (which is, at least, a possible supposition,) then the rays which proceed from it must be eternal also.

All the attributes and perfections of the Deity are manifested in the works of creation, providence, and redemption. The curiosity of men has led them to inquire what has moved the divine mind to these manifestations of wisdom, power, and goodness. As all the actions of men arise out of certain purposes which they have formed, and certain objects and ends which they have in view, we are naturally led to conclude that the same must be the case with the ways of God; they must have an origin, and they must be designed to accomplish certain ends. In other respects there must be a wide difference between the ways of God and the ways of men. We are influenced by motives, suggested by circumstances over which we have no control; the actings of the Almighty arise out of his own free will, uninfluenced by external circumstances, inasmuch as his purposes were formed before the foundation of the world, regulating, and not following the course of nature and of providence.

It is needless to attempt to conceal that no subject has excited more controversy that this: it forms the grand point of debate between the Arminians and Calvinists. Though we do not entertain any hopes of being able to put an end to the dispute, we nevertheless think it necessary to state the question; and we shall not be disposed to make any apology, though we should be discovered to bear more to one side than to the other.

The doctrine of predestination, which arises out of this subject, is unquestionably taught in Scripture (vide Rom. viii. 29. Eph. i. *passim.* 2 Thes. ii. 13. 1 Pet. i. 2.) It is also held as a fundamental doctrine by the Church of England, the Church of Scotland, and many other churches, and is necessarily connected with the fore-knowledge of God. "Whom he did foreknow, he also did predestinate." It will be proper, however, to remark that we may fall into great mistakes in talking of the *fore*-knowledge of God: for with him there is neither *fore* nor *after;* all things are eternally present to him; and by him, and in him, all things subsist. The language and the conceptions of men are formed on entirely different principles. We employ three principal tenses to mark the flight of time, and the course of our ideas, viz. the past, the present, and the future. But the grammars of men cannot limit the conceptions of the Almighty, whose existence is commensurate with eternity; "with whom a thousand years are as one day, and one day as a thousand years."

We can with difficulty form a conception of this, yet it is demonstrable that it must be so. It flows necessarily from the eternity and self-existence of God. All things being ordained by him; all the parts of the present dispensation being connected with, and adapted to each other; and no power being able to alter or withstand what he has decreed in his wisdom, and in his might, the whole system of things must necessarily be present to his mind. He sees those things, to which we would ascribe only a *possible* existence, as actually existing; and as the architect sees all the parts and proportions of the future palace, in the plan which he has formed in his own mind, before a single stone of the building has been laid, so the eternal architect saw, before the foundation of the world, the proportion, order, and use of every part of the visible system of things, which appear to us only in succession, and at distant intervals, and perplex us greatly in all our attempts to account for them.

In conformity with the ideas which have now been thrown out, we would rather say that predestination flows from the omniscience, than from the *fore-knowledge* of God. Nobody can doubt that he knows every thing that is come to pass. We see how intimately he was acquainted with the fate of nations when he announced beforehand the events which were to befal them. No one of these predictions ever failed. Now, whether we say that he merely foreknew these events, but decreed nothing concerning them; or affirm that they were fixed by his absolute decree, on either supposition, the result must be the same; they could not but happen as God had foreknown and foretold.

For God to predestinate, then, or to foreknow, seems to amount to one and the same thing; unless we run into the impiety of supposing that God foreknows things over which he has no control, which he did not plan, and which he cannot prevent. Such a supposition is altogether inconsistent with the sovereignty of God, as the ruler of the universe, and the disposer of all events. It is true, indeed, that foreknowledge, among men has no influence on the events which are foreseen. We may be so well acquainted with the character and disposition of individuals, that we may know, almost with absolute certainty, what they will do in given circumstances. We may be sure that pride will mislead one man, avarice another, and ambition a third; that one will be enslaved and led astray by vanity, and another by the lure of sensual indulgence. But though we may know all this with absolute certainty, yet our knowledge has no influence on the fate of the parties. The same would be true in regard to God, had he as little to do with the government of the world as we have; and did he come by his knowledge in the same way that we do. But his knowledge is the result of his own free will, which ours is not: we come to the knowledge of things by accident, or by application; but God knows all things from the beginning, because in him all things subsist; he knows every event before it is unfolded in the course of his providence, because it forms part of his eternal plans: in short, he knows all things, because he has ordained them.

The opposite scheme, or what has been called the Arminian view of this subject, does not remove a single difficulty, whilst it is attended with some inconsistencies which do not encumber the Calvinistic plan. It goes on the supposition that the decrees of God are fixed in consequence of the known characters of men, good or evil; that those, for instance, whom God foresees that they will be virtuous and obedient, he decrees to eternal life; whilst those who are foreseen to be contentious and disobedient are decreed to everlasting punishment. Thus, both on the Calvinistic and the Arminian hypothesis, decrees are admitted; for it is impossible to read the Scriptures and not perceive it to be a fundamental doctrine, that every thing which comes to pass is fixed and determined in the eternal counsels of God. The parties differ only in the way in which his decrees are to be explained. The Arminian scheme seems to make the counsels of God depend on the will of feeble man; and to countenance the idea that he may have done so much for the human race, and yet that it may be all in vain; that men may not choose to believe, and that, therefore, the intention of the Almighty may be defeated; all which notions seem directly contrary to the language of Scripture, which says, "whom he did predestinate them he also called," (Rom. viii. 29.) and as many as were ordained to eternal life believed." (Acts. xiii. 48.)

The great argument against the Calvinistic views on this subject is drawn from certain conceptions which men have formed respecting the divine character. It is argued, for instance, that it is inconsistent with the benevolence of the Deity to decree any one to eternal misery. The apostle (Rom. ix.) answers this objection by resolving the fate of men into the absolute sovereignty of God; and turn which way you will, or adopt what view of the subject we please, we shall find that we must land in the same conclusion at last. If misery is to be the portion of any in the future world (and this has never been denied by any) it may just as well be affirmed that it is inconsistent with the goodness of God to make creatures who he knew would be miserable, as to maintain that it is inconsistent with his benevolence to doom them to misery by his absolute decree.

They, then, do not remove a single difficulty who say with the church of England, and some other churches, that God does not predestinate any man to misery, because predestination does not condemn but save men, inasmuch as all men were under a curse, and liable to punishment, to which they must have been subjected, had not God, in his eternal counsels, resolved to save a certain number, whilst the rest were *passed over*, and left to the fate which sin had brought upon them. This is merely disguising the difficulty; to *pass over* any in the decree of election is the same as to doom them to hopeless reprobation; it is attended with all the same consequences, and can be explained only on the same principle, viz. the sovereign will of God.

It is farther argued that the doctrine of absolute decrees is calculated, on the one hand, to drive men to despair, or, on the other, to encourage arrogance and presumption; that those who conceive themselves doomed to misery, must be driven to desperation; whilst those who conceive themselves ordained to life will be careless and presumptuous. It is easy to get rid of this objection. The decrees of God can have no influence on human conduct, whilst they are unknown; and in so far as they are made known, the tendency is salutary, calculated to encourage virtue and repress vice and immorality, for this is his fixed and irreversible decree, that the man who lives humble and holy, and dies in faith and hope, shall inherit eternal life, whilst "the unbelieving and disobedient shall not see life, but the wrath of God abideth on them." (John iii. 36.) So far every man may know, and ought to know, the decrees of God; and he should not seek to know more. Were every man permitted to read his fate, as written in the unalterable records of heaven, there would be an end at once both to the restraints on vice and to the encouragements to virtue.

But, in concluding this subject, we would observe that the difficulties which encompass it do not arise out of the Scriptures; they arise out of some of the most obvious doctrines of natural religion; and they are greatly lessened, and some of them almost entirely removed by the light of revelation. It may be observed, for instance, that it is decreed concerning every man that lives, that he shall be happy or miserable in the future world. This is a doctrine which never has been doubted; all men, in all ages, have admitted a state of rewards and a state of punishments beyond the grave, in the one or the other of which, every human being must have his future portion. This is a settled point, in which all are agreed. Supposing, then, that we had know nnothing more than this, and had never heard of predestination and election, would our anxieties have been less than they are, and would we have been perfectly at ease with regard to our future prospects? No, the heathen who knew nothing about God's eternal purpose to save those who believe on his Son, were deeply anxious and perplexed about their condition in the future world. "Shall I give my first born for my transgression, the fruit of my body for the sin of my soul," is the inquiry of a heathen, and of one deeply anxious to secure his soul's salvation, and willing to make great sacrifices in order to accomplish it. This inquirer was more rational in his views than many professed Christians; for he concluded that something was to be done that he might enter into life, whilst many who profess the faith of Christ seek to ascertain their future condition by prying into the hidden counsels of God, and instead of acting as he has commanded, sit moping and disconsolate, waiting till he shall be pleased to reveal to them his secret purposes. This is altogether unreasonable; God has made no secret of his purposes in regard to any man living. "He hath showed thee, O man, what is good." "If thou wouldst enter into life, keep the commandments." "Do these things, and thou shalt never fail."

God having determined in his eternal counsels to manifest his attributes and perfections, he gave birth to the visible creation; and having stored the earth with abundance, and replenished it with living things, he, at last, crowned his work by creating man, and constituting him lord over this lower world. He was made in the image of God, which implies that he was free from natural infirmity and moral imperfection. His body was then immortal; he was to be subjected to death only in case of disobedience. His fall was accomplished through the temptation of the devil, and he instantly became liable to death, and the subject of moral corruption. The punishment was not confined to himself. "In Adam all died," both naturally and morally. The fountain head being polluted could not be expected to send forth a pure and limpid stream; it would have been contrary to every thing which we observe in the analogy of nature to suppose that man, the prey of death and sin, should produce a pure and immortal offspring; and there is no more difficulty in conceiving how we should derive sin, disease, and death from Adam, than there is in conceiving how the various tribes of animals have the tempers, defects, and vices which belong to their species. On these points we cannot dwell, as we must hasten to consider the nature of the remedy which God, in his wisdom, had provided, and which was rendered necessary by the helplessness and desperate depravity of men.

Some of the wiser among the heathens had expressed their belief that a divinely inspired teacher was necessary to instruct mankind in their duty. The Jews had a firm persuasion that such an instructor would be sent; they viewed him, however, in a higher light than that of a mere teacher, and considered him as commissioned by God to redeem them from the power of all their enemies. This belief was fostered by the particular circumstances in which they were placed. It is probable that had they preserved their power and importance among the nations, they would have paid too little attention to the prophetic declarations respecting the great deliverer who was promised to them. But they had been for several hundred years a humbled and depressed people. This made them scan, with the nicest attention, all the intimations of the prophets respecting this remarkable personage; and they were so completely versant in all the records concerning him, that they had ascertained the very time when, in conformity with predictions whose inspiration was universally acknowledged, he ought to be expected.

This deliverer was known by the name of *the Messiah*, or the Christ, (both of which words signify *anointed*) long before the appearance of Jesus of Nazareth. He had been designated by this title by the prophet Daniel, who pointed out, in very intelligible terms, both the time of his appearing and the end for which he lived and died. Dan. ix. 24, &c. Accordingly the Jews were living in anxious expectation of the advent of the promised Messiah. Nor were they the only people who entertained such hopes; the Samaritans also had the same expectations, as appears from the words of the Samaritan woman in her conversation with our Lord. She does not appear to have been remarkably distinguished either by knowledge or virtue, yet she was perfectly acquainted with the expectations which generally prevailed respecting the Messiah. "I know," says she, "that Messias cometh, who is called Christ; when he is come he will teach us all things." John iv. 25. Suetonius farther informs us, that an opinion was prevalent over all the east, that a person was to come out of Judea who should obtain the government of the world. This expectation he supposes to have been fulfilled in the case of Vespasian, who went from Judea to mount the throne of the Cæsars.* Tacitus mentions the same circumstance.†

This prevailing opinion accounts for the circumstance of the wise men coming from the east to Jerusalem, to inquire for him who was born King of the Jews. They had seen some extraordinary meteor, or luminous appearance in the heavens, perhaps the same which shone round the shepherds in the plains of Bethlehem on the night of the Saviour's birth; and they concluded that it was a signal to announce the birth of the expected Messiah. When they reached Jerusalem, the same luminous appearance directed them to the house where Jesus was, and they offered him the gifts and homage which were due to a king.

We can be at no loss to ascertain the origin of these opinions and expectations. A continued chain of prophecies and supernatural communications, extending from the time of Adam to the last of the prophets, had prepared the minds of the Jews for the manifestation of the Messiah. The time marked out for the completion of these predictions falling in with the period of our Lord's birth, we read in Scripture of two impostors who availed themselves of the prevailing expectation, and collected a number of partizans to support their pretensions to the character and honours of the Messiah. Acts v. When John the Baptist appeared, he publicly assumed the character of a prophet; and his pretensions were instantly and universally acknowledged. No prophet had appeared in Israel since the days of Malachi, till the appearance of John the Baptist; a dreary interval of about four hundred years. John was therefore joyfully hailed as a prophet, and "all men mused in their hearts of John, whether he were the Christ or not." Luke iii. 15.

In these circumstances, and in the midst of these expectations, Jesus was born at Bethlehem, in conformity with the intimations of prophecy, though to appearance he was born there from the accidental circumstance of Joseph and Mary being called up to be enrolled at Bethlehem, the principal city of their tribe.

Though descended from the family of David, he was born in humble circumstances, and had no attractions of wealth or dignity to recommend him in the eyes of his countrymen. This proved a great obstacle to the reception of his doctrine among the Jews; and, indeed, more than they have been inclined to think, that it would have been more consistent with the character of a heaven-commissioned teacher, to have had more weight and authority, in order to give more extensive influence to his doctrine. But if the plan is from God, we may rest assured that the circumstances in which it was developed were the most proper, and most conducive to promote the end in view. This, indeed, seems to be a point that may easily be demonstrated. For, in the first place, his humble condition gave mankind the most favourable opportunity of examining his pretensions. Their imaginations were not seduced by the imposing circumstances of high reputation, of high rank, and of powerful family connexions. The prejudices of his countrymen were all on the other side; they received his doctrines with distrust, and fortified their unbelief by such observations as these, "Is not this the carpenter's son? Is not his mother called Mary? and his brethren James, and Joses, and Simon, and Judas? and his sisters, are they not with us? Whence then hath this man all these things?"

Is it not obvious that all these circumstances, which excited, at first, such strong prejudices against the person and the doctrines of our Lord, contribute most powerfully to strengthen that evidence by which his religion was ultimately established? Had he been received with immediate acclamations as the promised Messiah, his success would have been ascribed to popular delusion, and

* Percrebuerat Oriente toto vetus et constans opinio, esse in fatis, ut eo tempore Judea profecti rerum potirentur. Vita Vesp. c. 4.

† Pluribus persuasio inerat antiquis sacerdotum literis contineri eo ipso tempore fore ut valesceret Oriens profectique Judea rerum potirentur. Hist. b. 5.

to the want of a cool and dispassionate scrutiny of his pretensions. But it is clear that every inch of ground was disputed, and the world did not yield till it was absolutely subdued by evidence which it could no longer resist.

But farther, the humble condition of Christ was peculiarly appropriate to his character as a teacher; and had he been differently circumstanced, he could not have fulfilled some of the important objects of his mission. Viewing him as a teacher, what would have been the consequence had he been surrounded with outward pomp and splendour? It would have defeated all his instructions, and he could not have "left us an example that we should follow his steps." Had he been in the circumstances supposed, he could not have said, "Learn of me, for I am meek and lowly;" "I come not to be ministered unto, but to minister." He could not have commanded his disciples to deny themselves, and take up their cross and follow him. Such an injunction would have been quite inappropriate had he been placed in circumstances where self-denial was never exercised, or where patience and fortitude were never required. He was placed in circumstances which afforded an ample display of all those virtues which we ought to imitate. Had he appeared as a temporal prince, his followers would have been intoxicated with vanity and ambition: had he appeared in the radiance which usually accompanied the manifestation of angels, men would have been deterred from approaching him, and would have deemed it presumption to attempt to imitate him; but he exhibited an exemplification of all the virtues which he recommended, and being surrounded by the wants and all the external evils which accompany our nature, he has left the most perfect pattern of meekness, resignation, patience, and fortitude.

If a teacher, then, was to be sent from heaven for the instruction of mankind, which even Socrates conceived to be necessary, it is impossible to conceive him placed in more favourable circumstances for discharging this important part of his office than those which marked the whole life and ministry of Jesus of Nazareth.

But we must look a little more minutely into his character before we proceed to consider the great work which he came to accomplish. In this investigation we must be guided by the intimations of Scripture, subjecting them to the rules of sound criticism, and not forgetting the most essential of all rules, viz. to make Scripture its own interpreter, and to explain the passages which appear obscure, by reference to those whose meaning is incontrovertible. A very different plan, however, is adopted by one Christian denomination. For they who call in question the divinity of Jesus are forced to take their stand on texts of doubtful meaning, which they interpret according to their prejudices and preconceived opinions, and then endeavour to reduce the plainest texts of Scripture to a standard which has no existence but in their own fancies.

The first intimation of the personal dignity of Jesus is conveyed in the annunciation of the angel to his mother, "The Holy Ghost shall come upon thee, and the power of the holiest shall overshadow thee; therefore, also, that holy thing which shall be born of thee shall be called the Son of God." Luke i. 35. There is here a style and formality entirely novel; nothing like it was ever said of any of the ordinary children of men. Our translation does not convey the full force of the original, which is literally "the born holy" (το γεναμενον άγιον) shall be called the Son of God. This marks his filiation to God, by a character not applicable to any of the sons of men. He was born holy; and this cannot be predicated of any ordinary mortal, who is conceived in sin, and shapen in iniquity. Ps. li. 5. This inborn holiness of Christ was necessary to the efficacy of his atonement; for it would be in the highest degree absurd to suppose that a creature, possessing the sinful infirmities and imperfections of human nature, should be able to make an expiation for the sins of men.

But the text which has been quoted only leads us to conclude, by legitimate inference, that Jesus could not be the Son of Man by ordinary generation. The Evangelist John goes a great deal farther, and commences his history of the life of Christ with these remarkable words, "In the beginning was the word, and the word was with God, and the word was God: the same was in the beginning with God; all things were made by him, and without him was not any thing made that was made." I have already endeavoured to show that St. John uses this language in conformity with the received notions among the Jews, who always spoke of the Word as a divine person. It would be sufficient, then, to show that the sacred writer applies the designation of *the Word* to Jesus of Nazareth, to satisfy us of the view which he entertained of his character. On this point he leaves us in no doubt; for in the course of a few verses, he says, "the Word was made flesh, and dwelt among us, and we beheld his glory, the glory as of the only begotten Son of God, full of grace and truth." Thus, then, St. John describes Jesus of Nazareth by the appellation of the Word; and the Word he identifies in every respect with God; he was with God, and he was God. This text is important in more views than one; for it not only asserts the divinity of Jesus Christ, but points out most distinctly a plurality of persons in the Godhead; it affirms, in the first place, that the Word was with God, to indicate a diversity of persons; and, in the second place, that the Word was God, to point out an identity of essence.

This is one of those clear and decisive texts which one would think it impossible for ignorance to misunderstand, or sophistry to pervert. But this does not hinder the determined prejudices of the Socinians from attempting to explain away the pre-existence and deity of Christ, as indicated in this text. To accomplish this hopeless object, they explain the words "in the beginning" as applying not to the beginning of creation, but to the beginning of the Christian dispensation; it was not till then, they say, that the word was with God; and thus they affirm that Christ had no existence till he appeared in the flesh to instruct mankind. This is a fair specimen of Socinian criticism, and we may judge what degree of deference is due to it, when we see the patrons of this system affirming that he, of whom the evangelist declares that he made the world and all that is therein, had no existence till he was born in Bethlehem. That a deist should hold such an opinion is natural and intelligible; but it exceeds all reasonable indulgence that persons should pretend to form their creed on the Scriptures, and yet should go directly in the face of their most obvious meaning.* They will say, indeed, that they found their arguments on criticism: they do so, but it is such criticism as Socinian interpreters only can admit; it is contradicted by the whole authority of the learned of all ages and nations; and before their system can prevail, they must have influence not only to supercede all the existing versions of the New Testament in the different languages of the world, but they must set aside all the received lexicons and glossaries, and get the world to adopt a new system of Socinian Greek. In fact, according to the mode of interpreting employed by these theologians, the New Testament, instead of being a revelation of divine truth, is an *enigma*, concealing under its most obvious meaning a series of puzzles which would require more than an Œdipus to unriddle them. And if this record of our faith was not written under the influence of inspiration, as Socinians contend, an inspiration would, at least, be necessary for every one who interprets it according to their method; for he must leave the obvious meaning, and torture every obnoxious text till it can be reduced to the standard of Socinian orthodoxy.

We shall adduce a few plain passages declaratory of the divine nature of Jesus Christ, and then we shall consider the collateral evidence by which these declarations are confirmed.

It is admitted by all, that Jesus called himself, and allowed himself to be called the Son of God. "We believe, and are sure, says St. Peter, that thou art that Christ the Son of the living God." But it will naturally enough be inquired, what is implied in the title of *the Son of God*. Its full import no mortal can explain: but that our Lord meant it to imply his equality with God, is sufficiently clear, if language has any meaning; and it is no less clear that both his disciples and his enemies understood it in this sense. Thus when the Jews murmured because our Lord had healed a man on the Sabbath day, John v., he thus addressed them, "My father worketh hitherto and I work." Upon this we are told "the Jews sought the more to kill him, because he not only had broken the Sabbath, but said also that God was his father, *making himself equal with God*." Such was the meaning which the Jews attached to his assertion that God was his father. Is he at any pains to correct these impressions? Does he tell them that they had affixed a wrong meaning to his words? Quite the reverse; for he immediately addresses them in language more explicit than before; and confirms the inference which they had drawn respecting the high dignity which he had assumed. "As the Father raiseth up the dead and quickeneth them, even so the Son quickeneth whom he will. For the Father judgeth no man, but hath committed all judgment to the Son, *that all men should honour the Son even as they honour the Father*."

Again, in the tenth chapter of John, our Lord says, "I and my Father are one." The Jews considered this blasphemy, and immediately took up stones to stone him. Upon this he said to them, "Many good works have I showed you from my Father; for which of those works do ye stone me? The Jews answered him saying, for a good work we stone thee not, but for blasphemy, and because that thou, being a man, makest thyself God." It would have been an easy matter for our Lord to have vindicated himself from the heavy charge of blasphemy, by disclaiming the inference which the Jews drew from his words; but instead of this, he only states additional arguments to confirm them in the conclusion which they had formed, for he says, verse 37, "If I do not the works of my Father, believe me not; but if I do, though ye believe not me, believe the works, that ye may know and believe that the Father is in me, and I in him." The works to which he alludes were the miracles which he publicly performed. It is impossible to admit the reality of these miracles without admitting at the same time his pretensions to a divine character in their full extent; and the reality of these miracles was never doubted by those who had the best opportunities of judging. The Jews and all the first adversaries of Christianity never attempt to deny them; on the contrary, they endeavour to account for them on the supposition that they were wrought by magic, or by the power of the devil, a mode of explanation which a modern infidel would be ashamed to adopt.†

Admitting, then, that our Lord actually performed these wonderful works, we must likewise admit that they afford complete confirmation of his extraordinary pretensions. For he must have performed them either by a power inherent in himself, or derived from God. If he possessed power in himself, his divine character is, by that very circumstance, completely established; for God alone is possessed of proper and inherent power; or if he derived his power from God, in that case the Father is bearing attestation to the doctrines of his Son, and declaring that his pretensions to a divine character, and to divine honours, are well founded; for the Almighty would never lend his power to establish a falsehood, or to countenance pretensions which interfered with his own glory.

It is impossible for any one who reads the gos-

* Besides the first verses of the Gospel by John, we refer the reader to the following passages, all of them expressing the pre-existence, and many of them the deity of Jesus. John i. 15—30, iii. 13—31, vi. 62, viii. 58, xvi. 28, 1 Cor. xv. 47, 2 Cor. viii. 9. Those who wish to see the Socinian interpretation of these passages, and the refutation of it, may consult Dr. Hill's (of St. Andrews) Lectures on Divinity, vol. ii. p. 23; a work deserving the attention of every student of Divinity.

† Jortin observes that the Christians were called *Malefici*, Magicians, by Suetonius, which is a virtual acknowledgment of the miracles which they performed.

pels with attention, to entertain the smallest doubt that Jesus Christ decidedly and unequivocally asserts his claim to a divine nature. It is true, indeed, that he very frequently calls himself the "Son of Man;" and we are taught, by the general strain of Scripture, to consider it as essential to his mediatorial character that he should assume the nature of man. "In all things it behoved him to be made like unto his brethren, that he might be a merciful and faithful high priest in things pertaining to God, to make reconciliation for the sins of the people." Heb. ii. 17. But as has been well observed,* there is a manifest peculiarity in the frequency with which our Lord assumes the designation of the "Son of Man;" he was guarding against the error of denying his humanity, which was not long of creeping into the church; he therefore assumes an appellation which none of the ordinary sons of men ever think of applying to themselves, because in their case it would be ridiculous to announce as a truth, what, in fact, is a truism, and never was denied by any human being. But there might have been room for doubting it in the case of our Lord, who exhibited such unequivocal proofs of divine power and omniscience. He therefore assumes an appellation peculiarly honourable to our nature, and implying a truth essential to our comfort; and by the frequency with which he repeats it, he shows that he was more anxious to be considered man, than afraid of being denied to be God.

It is very singular that almost all those who have questioned or denied our Lord's divinity, have bestowed high praise upon him as a wise and virtuous man, and as an enlightened teacher of morality. But they who do not allow him to be more than man, ought, like the Jews, to consider him as a blasphemer, for he publicly and repeatedly taught, and indeed it seemed to be the point on which all his doctrine hinged, that he and his Father were one; and he declined not the homage of religious adoration, when Thomas addressed him, after his doubts were removed, in language appropriate only to the Deity, "My Lord, and my God." Does our Lord rebuke Thomas for using language which was positively impious if applied to any mere man? If there is any rebuke implied in our Lord's reply, it is because Thomas had been too tardy in recognising the truth which he at last avowed. "Thomas, because thou hast seen me, thou hast believed; blessed are they who have not seen and yet have believed." John xx. 29.

This part of the argument might be carried to much greater length, and might be strengthened by a great number of quotations from the gospels, all equally decisive as to our Lord's divinity. But it cannot be necessary to multiply texts on this subject; neither ingenuity nor sophistry can explain away the plain import of the passages already adduced; it is not in the power of language to express more clearly these important truths, that Jesus in his lifetime advanced claims to a divine nature; that his apostles recognised these claims; that his enemies publicly charged him with blasphemy for advancing them; and that on such occasions he not only did not withdraw them, but supported them by additional arguments.

The testimony of Pliny is not unimportant to show how early divine honours were paid to Christ. In a letter to the Emperor Trajan, giving an account of the transactions in his province, where the Christians had become numerous, he states the manner in which he had proceeded with them; he mentions that he had inquired into their particular opinions, and that his information on this point amounted only to this, that "they were accustomed to meet on a stated day, before it was light, and to sing a hymn to Christ, as to God."† Dr. Priestley engaged in the desperate undertaking of attempting to prove that the early opinions concerning Christ were unfavourable to his divinity. He has been answered by Dr. Horsley, and has been absolutely overwhelmed and crushed by the force of his arguments and the extent of his learning.‡

But in maintaining the divine nature of Christ we are not to forget his humanity. It is an essential article in the orthodox creed that he is both God and man. And so intimately are the two natures connected, and yet so distinct are they in their properties, that he is sometimes spoken of in Scripture, as possessing only the attributes of God; and at other times as endowed exclusively with the feelings and faculties of man. He is "God over all blessed for ever;" and he is also the "man of sorrows and acquainted with grief." Sometimes he manifests his divine power, and multiplies a few loaves and fishes, so as to be sufficient for the supply of five thousand people. At other times we read of his being faint and hungry, and destitute of the ordinary comforts of life. Sometimes, when speaking of himself as man, he seems to state limitations both to his power and his knowledge; at other times he asserts all the prerogatives of divinity, and lays claim to the same honours which are due to the great Father of all. But all these passages are easily understood, if we bear in mind that Jesus had a proper divinity as well as a proper humanity: and that the same thing cannot be predicated of these two natures. Each of them has a distinct character not applicable to the other.

There is also a third character in which he appears, viz. that of a mediator, which has a distinct and appropriate office, and of which certain circumstances may be predicated which are not applicable to Christ either in his divine or in his human nature, when separately considered. Thus when he says that *he can do nothing of himself but as he is commanded by the Father*, he speaks of his mediatorial office, in which a definite work was given him to perform, and from which he could not possibly deviate without frustrating the work of God, and deserting the enterprise which he had undertaken. In this respect, a limitation was laid even on his own omni-

* See Magee on the Doctrine of Atonement and Sacrifice.

† Affirmabant hanc fuisse summam vel culpæ suæ, vel erroris, quod essent soliti stato die ante lucem convenire; carmenque Christo, quasi Deo, dicere secum invicem. Plin. Epist. Lib. 10.

‡ See Horsley's Letters to Priestley.

potence; and he was bound to fulfil every article stipulated in the eternal covenant between him and the Father. Yet, in all this, his power was restricted only by his own will; and he submitted to a voluntary humiliation, and a voluntary relinquishment of power, that he might accomplish a work which could not by any other means have been effected.

Though we ought carefully to abstain from all attempts to explain the manner of the Incarnation, yet it is neither improper nor unprofitable to consider the consequences which have resulted from it, and even to illustrate them by analogies drawn from sources of knowledge more immediately within the reach of our faculties: and I have no hesitation in saying that the Incarnation of the Son of God, instead of appearing an objectionable doctrine, presents to us the most interesting, perhaps the only intelligible view of the Almighty, and of the duties which we owe to him. When men take what they are pleased to call a philosophical view of the nature of God, they are soon lost and overwhelmed in the immensity of the subject; for what conception can we form of a being without beginning and without end; without appetites, without passions, without bodily form; incapable of being injured by our sins, or benefited by our services? Such a being as this (and it is only as such that the light of reason can recognise God,) must appear rather as an abstract conception of the mind, something resembling the fate of the heathens, than as an object of love, gratitude, and adoration. On this account, the most philosophical inquirers, who have not had the light of the gospel for their guide, have been bewildered in the vast generality of the subject; and have regarded the supreme being rather as an object of speculative contemplation, than as entitled to the affections and the worship of his creatures. The ignorant and uninformed fell into an opposite error. They could form no conception of God, but as of a being resembling themselves; and hence they represented him by forms and images adapted to their prejudices and feelings. All these inconveniences and sources of error are removed by the Incarnation of the Son of God, which was manifested in condescension to our weakness, to show the tender care, the paternal love, the constant providence of our heavenly Father.

We have now a definite object of worship, in the person of the Son of God, in whom "dwelt all the fulness of the Godhead bodily," who was once a visible and tangible object of affection; who still retains, at the right hand of God, the human nature along with the divine, and who is still establishing additional claims to our gratitude and love, by making continual intercession for us. We have now, as it were, a palpable object of worship, accommodated, as far as possible, to the circumstances of our nature and of our feelings, exhibiting, in our form and likeness, all those splendid and divine qualities which are calculated to excite religious homage, and all those feelings of brotherly kindness and charity, which ensure our love and our imitation.

In short, the incarnation of Jesus Christ, though it involves a mystery far exceeding our comprehension, is nevertheless in perfect conformity to the preceding dispensations of God. Under the law, God was pleased to establish certain visible representations of himself to aid the conceptions of the Jews, and to remind them of his presence: the ark, and the cherubim, and the cloud, were viewed with the most profound veneration, as emblems of the divine presence: and besides this, God often condescended to converse with men in a visible form, and to give to them immediate intimations of his will. But certainly a much more lively and interesting, and impressive representation of the divine majesty was given in the Incarnation of Christ, by which "The Word became flesh and dwelt among us and we beheld his glory, the glory as of the only begotten of the Father, full of grace and truth."

Instead, then, of having any doubt whether we ought to yield religious homage to the "Son of Man," we ought to conclude that there is no other way of worshipping God, with acceptance, but through him. There is a vast emphasis of meaning in our Lord's words, when he says, "I am the way, the truth, and the life, no man cometh unto the Father but by me." These words not only imply that Christ is the way by which men come to the enjoyment of God in his heavenly kingdom, but that there is no other way in which we can form any accurate conception of him, or yield to him a rational service. "No man hath seen God at any time; the only begotton Son which is in the bosom of the Father, he hath declared him." This is the nearest approach to an open vision of the Almighty that ever has been, or can be made by mankind in the present world. We cannot behold him in his glory, for no man can see his face and live. But we see his glory shining with a mild radiance, and a qualified lustre, in the person of his Son, not so intense as to prevent us from approaching him, or deter us from imitating him; but drawing us to God by the most powerful attractions, and teaching us to aspire to the imitation and the enjoyment of the Father of our spirits. We are thus brought near to God by the incarnation of his Son, who assumed our nature that we might rise to the resemblance of his; and, by imitating his example and imbibing his spirit, might at last vindicate our claim to the glorious title of sons of God.

The prophecies which Christian authors have interpreted as fulfilled in Christ, are admitted on all hands to have existed long before he appeared on earth. They are publicly cited by his apostles, in their discourses to their countrymen, and appealed to as affording the most unexceptionable evidence to the truth of the Gospel.

To the Jews such evidence ought to have been decisive. They knew the history of the prophecies: they themselves had the keeping of them; and they had embraced them as forming the foundation of their hopes: they could therefore entertain no suspicion that they had been fabricated for any particular purpose. The prophetic writings were sufficiently clear to warrant certain conclusions, such as the appearance of the Messiah, the time of his advent, the universality and perpetuity of his kingdom. On these points there was not the slightest ambiguity; they are stated in the most unequivocal language, and they formed a part of the creed of the Jews several centuries before the time of Jesus of Nazareth.

But whilst the leading features of the prophecies respecting the Messiah were so clear, the details or the filling up of the scheme were involved in intentional obscurity, that men being left to their own volitions, and unconstrained and uninfluenced by the foreknowledge of events, might become the unconscious instruments of accomplishing the designs of heaven. Had the Jews distinctly understood the predictions respecting the death of Christ, and known that it was to be an essential circumstance in the character of the Messiah that he should be crucified by those whom he came to save, it would have been impossible for such an event to have been accomplished. They would not have put to death one whom they received as the Messiah: their reception of him would have been altogether inconsistent with such an act of violence, and they would not have insisted on the crucifixion of one whom they deemed an impostor, lest by this very act they should strengthen his pretensions. This, therefore, was "The wisdom of God in a mystery, which none of the princes of this world knew, for had they known it, they would not have crucified the Lord of Glory." 1 Cor. ii. 8.

This obscurity in the prophecies of Scripture must not be supposed to bear the most distant resemblance to the studied ambiguity of the heathen oracles. These were only consulted with regard to events immediately future; men take little interest in what is very remote in its date and consequences: there was, therefore, the utmost need for caution, lest, by a rash response, the credit of the oracle should be weakened or destroyed. The answers were, accordingly, so contrived as to flatter the hopes of the inquirer, and, at the same time, to save the credit of the oracle in case of failure. There is a most remarkable difference between such responses and the oracles of God. The latter are never ambiguous with regard to events immediately future, whose occurrence is determined by circumstances which have already happened, though their result and issue may be entirely unknown to men. Thus, Jeremiah made no mystery of the captivity of the Jews which was to take place in his own time; whilst to comfort them, he announced its termination, after a lapse of seventy years. In the same manner our Lord declares that Jerusalem should be utterly destroyed, before the generation which heard the denunciation should pass away. The same observation applies to all the prophetic announcements in Scripture, which apply to events immediately future. The intimations of Joseph to Pharaoh, of Daniel to Nebuchadnezzar, of Samuel to Eli; are delivered without the slightest ambiguity, or attempt at concealment. No provision is made for evasion in case of failure; the credit and the safety of the person who announces the will of heaven are fairly staked on the issue; and in all these cases, the result has been such as to produce implicit faith in the predictions respecting distant and darkly intimated events.

But there is not the same clearness of meaning when the prophecy relates to events of remote date, and of momentous importance in the history of the world, or of the church of God. It is then veiled in figure, in allegory, and in mystery; though we may discern a dark outline we cannot complete the picture; and we must wait with patience till it stands revealed by the evolution of events, which completely interpret the previously intimated counsels of heaven. The use of such prophecies is rather to convince mankind of the constant universal providence of God, than to lift the veil from futurity; and whenever an event occurs which, by the circumstances attending it, can be proved to have been foretold, that event bears the signature of heaven to its truth, and its importance in the economy of providence.* In short, it seems to have been the intention of the Almighty that events should explain the prophecy, rather than that the prophecy should make mankind fully acquainted with future events. It is evident that the prophet, in foretelling distant events, had no inducement to affect mystery where there was no danger of being detected, and where he had so many opportunities, had he been an imposter, of advancing his interest, by flattering the prejudices of his countrymen, or of indulging his malignity by terrifying them by unequivocal denunciations of judgment.

Indeed, there is every reason to think that the prophets themselves were unacquainted with the meaning of many of the most important predictions which they delivered. They had visions and dreams in which certain representations seemed to pass before their view, and certain words seemed to reach their ears. They knew they were under a prophetic influence, and that they were bound to record faithfully what they had heard and seen. But they gave themselves no concern about the interpretation; nor do their countrymen ever press them for an explanation of their dark and mysterious intimations. They related all that God had been pleased to reveal, and they would have deemed it presumption to have pryed farther into the secrets of heaven. God reserved to himself the interpretation of his own counsels; and, by the events of his providence, demonstrated that he ruled in the armies of heaven, and regulated the affairs of the children of men.

The first prophetic intimation of the Messiah is supposed to be contained in the promise that the seed of the woman shall bruise the head of the serpent. The promise is afterwards renewed to Abraham, for it is said that in him all the families of the earth should be blessed. This promise has never received a literal fulfilment, by any temporal blessings conferred on the human race, by the natural seed of Abraham; but it has been completely fulfilled, or is in the progress of being fulfilled, by the

* Gibbon calls prophecy an *argumentum ad hominem*, applicable only to the Jews who believed in its truth. We, on the contrary, contend that it is an evidence equally applicable to all who admit that the prophecy existed before the event which explains it.

blessings which Christ, his lineal descendant, according to the flesh, has conferred, and is still conferring on the human race. The prophecy of Jacob on his deathbed, has been universally understood by Jews and Christians to apply to the Messiah. "The sceptre shall not depart from Judah, nor a lawgiver from between his feet, till Shiloh come, and unto him shall the gathering of the people be." This prophecy defines with considerable precision the time of his appearing. Moses, shortly before his death, said to the Israelites, "The Lord thy God will raise up unto thee a prophet, from the midst of thee, of thy brethren, like unto me; unto him ye shall hearken." This prophecy is applied by the Apostles (Acts iii. 22) directly to Jesus of Nazareth.

The prophet Isaiah (ch. liii.) points out more particularly the peculiarities in the character and history of the Messiah, his innocence, his sufferings, and the object which was to be accomplished by them. The sixty-nine weeks of Daniel, which were to elapse between the rebuilding of Jerusalem and the cutting off "Messiah the prince," mark still more definitively the time of his suffering. In the interpretation of this prophecy, all divines consider a day as representing a year; and, according to the most accurate chronology, by calculating on this plan, the time of the Messiah's death will be found to be exactly defined.

We stop not to point out how completely these prophecies have been fulfilled. Almost all the prophecies, too, speak distinctly of the rejection of the Jews, for a season, at least, and the calling in of the Gentiles. How was the latter event ever to take place under the narrow and exclusive system of Judaism? The ordinances and ceremonies appointed to the Jews, were rather intended to keep them separate from the rest of the world, than to induce other nations to adopt their ritual. But the prophets announced a more liberal dispensation, by which all men were to be brought to the knowledge of the truth.

As an evidence of Christianity, prophecy has several advantages over miracles. A miracle is not generally presented more than once to the senses; a prophecy can, at any time, be steadily examined by the eye of the understanding. The evidence arising from the fulfilment of prophecy gathers strength by the lapse of time; and the great events which are successively evolved, in the course of providence, have all the effects of a miracle to strengthen our faith in a divine revelation. The Apostle Peter states, as the ground of his own conviction, the miracles which he had seen, and the voice which he had heard on the mount. So far as he himself was concerned this was quite sufficient; he states, however, another species of evidence more accessible to all mankind. "We have also a more sure word of prophecy; whereunto ye do well that ye take heed, as unto a light that shineth in a dark place, until the day dawn, and the day star arise in your hearts." (2 Peter i. 19.)

Modern infidels pay the highest compliment to the prophecies when they affirm them to be fabrications written after the events which they pretend to predict. This amounts to a confession that the events and the prophecies correspond with each other; and when this is admitted, it is the easiest thing in the world to prove the antiquity of the predictions. On this point the Jews and the Christians are as one; and though the former have suffered so much on account of their rejection of the true Messiah, whose pretensions are founded on the Law and the Prophets, yet nothing has been able to make them justify their unbelief, as modern sceptics affect to do, by denying the antiquity or authenticity of the Scriptures which testify of him.

It is a singular and striking feature in the evidences of Christianity that it founds its pretensions on the very records which the Jews had, for so many ages, been accustomed to respect: and it shows their reverence for the sacred volume, that though it contains so many distinct prophecies to convict them of obstinacy and wilful ignorance, they have yet never attempted to corrupt the sacred text, and make it more conformable to their prejudices. The vigilance of the Christians, indeed, would have rendered it impossible to execute such a design; for they instantly adopted the Jewish scriptures as their own, and guarded them with the most jealous care, as displaying the gradual development of that wonderful scheme which was perfected by the mission and sufferings of Jesus of Nazareth. The Jews felt themselves pressed by the authority of their own scriptures; but they did not dare to alter the original record. There was a translation, however, of the Hebrew scriptures in Greek, now commonly known by the name of the Septuagint, which was in very general use among the Jews in the time of our Lord. This translation had been used by the Jews residing in the Gentile cities, for upwards of two hundred years before the birth of Christ. It is chiefly from this version that the heathen authors derived their knowledge of the Jewish law, and of the doctrines of scripture; and we may judge of the accuracy with which it is executed from the circumstance of its being quoted by the writers of the New Testament. The Jews, finding this version as hostile to their notions as their own original scriptures, encouraged a new translation into Greek; but no effort has ever been able to subvert the clear evidence which stands against them in their own scriptures.

But the evidence resulting from prophecy is not to be confined to the predictions contained in the Old Testament scriptures. The prophecies delivered by our Lord and his apostles are equally conclusive to the same purpose. We allude merely to the unequivocal predictions which he delivered respecting the destruction of Jerusalem, and the rapid progress of his religion. The former event was not improbable from the character of the Jews; the latter was in the face of all human probability.

Yet, notwithstanding the low and suffering condition of Jesus, and the opposition and animosity which his doctrine excited, he uniformly expressed the most perfect confidence in the ultimate success of his religion. He compared it to a grain of mustard seed, which, though very minute at first, increases rapidly till it becomes a tree, and the fowls of heaven take shelter under its branches. The illustration is beautiful and appropriate, and has been verified by the event. He might have compared it to the oak which springs from the acorn, and, in process of time, becomes the ornament of the forest. Such an illustration would have pointed out the small beginning and ultimate stability of the gospel. But the mustard seed was a more appropriate emblem of the rapid growth and advancement of Christianity in the world. This certainly was an event little to be expected on any calculation of human policy. The religion of the Jews, with which Christianity was at first confounded, and from which it is not altogether distinct, was an object of contempt among the heathen nations, on account of its peculiarities and exclusive spirit, and the Jews themselves were viewed with a dislike bordering on abhorrence. How unlikely was it then that a religion, founded, as the heathens believed, on the peculiar institutions of the Jews, (though these, in reality, had been appointed with a reference to it,) should so speedily triumph over all the forms of religion which then existed in the world, which had been consecrated by the strains of the poet, mixed up with the civil institutions of the state, associated with the feelings and prejudices of the people, and protected alike by the arms and the eloquence of their votaries? Yet all these forms of religion vanished almost as rapidly as enchantments are supposed to do when dissolved by the counter-spell of some more powerful magician.

As Jesus Christ publicly claimed a divine character, and divine honours, he would have been destitute of the strongest evidence of his pretensions, had he not had the power of working miracles. When the evangelist declares that "by him all things were made," it would have amounted to a falsification of such pretensions, had he never demonstrated his power over the works of his hands. In consistency with this idea we find that whilst the prophets, under the Old Testament dispensation, referred all the miracles they wrought to the immediate power of God, the Apostles no less uniformly refer all their miracles to the power of Jesus of Nazareth; which is itself a demonstration that they conceived him possessed of divine power, and that they thought it not derogatory to God to perform miracles in the name of him whom he had sent.

It is farther to be observed that Christianity, (including under this name the religion of the Bible at large,) is the only system of religious worship professedly founded on miracles. Our Lord publicly appeals to them in confirmation of his doctrine, and as proofs of his divine mission. "I have greater witness than that of John," says he, "for the works which the Father hath given me to finish, the same works that I do bear witness of me that the Father hath sent me." John v. 36. All religions, indeed, have pretended to miracles; but with them they are continued; they are not referred to the infancy of the system which they are brought to support: they gain credence only after it has reached its full maturity, when superstition or political jugglery can give easy currency to pretended miracles which fall in with the national taste, humour and established prejudices.

Now consider the circumstances under which the Christian miracles are said to have been wrought, and observe how striking is the contrast. They are ascribed to the author of Christianity, and to his immediate disciples, to whom he delegated the task of converting the world. But with them they stopped: at least we have no sufficient evidence of a well-attested miracle, performed by their immediate successors: and none but the *charlatans* of the church of Rome, have ever pretended that they extended beyond their times. In the worst ages of this corrupted church its members began to revive pretensions to miracles, and obtained easy credit on account of the besotted ignorance of the people. Christianity rejects such miserable shifts; and being "built on the foundation of the prophets and apostles, Jesus Christ himself being the chief corner stone," it cuts off all attempts at quackery and imposition in after times, by with-holding from all the exercise of miraculous gifts.

We may safely affirm that it was absolutely impossible for such an extraordinary religion to be established in the world without miracles; and therefore God did not make such an unreasonable demand on our belief as to require our assent to it, without the most extraordinary and satisfactory proofs: he did not require us to receive on light grounds, and imperfect evidence, a religion which was to be "the savour of life unto life, or the savour of death unto death," but he exhibited demonstrations of power sufficient to convince even the senses of the generation to which the gospel was first addressed, and to satisfy the reason of all succeeding generations of the world.

But it is inconsistent with the plans of divine providence that miracles should be long continued; and it would be foreign to the constitution, and adverse to the interests of the human mind, were miracles interposed where the object can be obtained by the judicious exercise of the powers which God has given us, aided, as he has promised they shall be, by the influences of his Spirit: which influences, however, are given only to assist, not to supersede our exertions. Whilst, therefore, miracles were absolutely necessary to demonstrate the important truth that Christ "had power to forgive sin," for nothing less could have produced this conviction; it was not necessary after this point was established, that miracles should be continued; but a religion being fairly introduced, consistent with reason, and adapted to the wants, and to the best interests of men, we are left to form our opinion concerning it, from an attentive examination of the evidence on which it was originally founded, from its conformity to the general plans of divine providence, and from its adaptation to the circumstances of human nature. And if we examine the authentic documents in which the facts and doctrines are recorded; and attend at the same time to the evidence which an unprejudiced conscience must bear to the utility and intrinsic excellence of the doctrines and precepts of Christianity, we will be persuaded that no higher evidence of its truth can reasonably be demanded, or can, in the nature of things, be afforded. If a miracle were required to solve every doubt, the remedy would soon lose its efficacy; for the more frequently it was repeated, the weaker it would become, as was illustrated in the case of the Israelites in the wilderness, who, though fed and conducted every day by miracles, seem to have been no more affected by them than by the ordinary phenomena of nature.

In the establishment of a religion of such high pretensions as Christianity, which offers eternal life to those who receive it, and denounces the most awful judgments against those who reject it, we have a right to expect the strongest evidence that can possibly be afforded, consistently with the plans of God's government: and if we had our option as to the nature and extent of the necessary proofs, the mind can conceive nothing more decisive than the miracles performed by our Lord and his Apostles. But we cannot be so unreasonable as to expect that those signs and wonders are to be repeated to every successive generation: if any man will still require a sign from heaven to confirm his faith, he can only be gratified through the medium of candid and diligent inquiry into the nature and evidence of the miracles recorded in Scripture.

With regard to our Lord's miracles, the first thing deserving notice is that they were publicly performed; and that the account of them, in the very form in which it has come down to us, was circulated among the men of that generation which had witnessed them.

It ought to be observed also, that our Lord's miracles were not disputed by the early opponents of Christianity. Their attempts to account for them amount to an admission of their reality. Julian, the apostate, does not deny the fact of the five thousand being fed, apparently, by five loaves and two fishes, but he accounts for it by ascribing it to the power of magic, or to some illusion wrought on their imagination. They who can swallow this need not bogle at any miracle, for we can conceive nothing more miraculous than that five thousand hungry men should be satisfied with an imaginary feast.

It was reserved for modern unbelievers to dispute facts which remained uncontroverted by the only persons who had it in their power to give an effectual refutation, by an unequivocal denial of the statements, had they known them to be false. Yet this was never done: unreasonable as the first adversaries of Christianity were, they did not dare to show the extent of their prejudice and animosity, by denying what thousands could attest on the evidence of their own senses. And on the same principle the evangelists boldly state, and publish to the world what they knew the most inveterate of their enemies would not dare to contradict. They make no parade in the statement of these miracles: to them they were not wonderful; for they knew that nothing was impossible to him who performed them: they show no anxiety to conciliate belief; it never entered into their mind to suppose that there could be any doubt on the subject: they therefore state them as simple historical facts, for the information of those who were not eye-witnesses of them; and the time and circumstances in which they were published may be considered as equivalent to a challenge to the whole nation of the Jews, to contradict, if they could, any one of their statements.

Take any one of the miracles which our Lord is said to have performed, and think how impossible were the means of imposition. Would any persons, in possession of their senses, have affirmed in the face of thousands who could have refuted them, had they deviated from the truth, that Christ fed five thousand persons in the wilderness with five loaves and two fishes, and that twelve baskets of fragments remained after the feast; that he raised Lazarus from the dead, after he had been four days in the grave, in the presence of a great number of persons who had gone from Jerusalem to condole with his sisters; that great multitudes went out to meet Jesus on his approach to Jerusalem, and that one great motive was that they might see Lazarus who had been raised from the dead? Would any one have ventured to affirm that the sun was covered with darkness during the space of three hours, when our Lord was on the cross, had not this been a fact notorious to the whole land of Judea? The most barefaced impostors that ever lived never dared to vent such falsehoods as these, in the face of thousands, who had the evidence of their own senses, or the testimony of numberless eye-witnesses to contradict their assertions. And had the evangelists been guilty of such extravagance, they must not have been impostors but madmen; and the history of their phrenzy never would have survived to excite the astonishment of the world: or if it should be affirmed that they were really mad, then the world must be concluded to have been as mad as they, to have believed their account, or to have allowed their extravagant assertions to pass uncontradicted, when the impression which they made became obvious. and in considerably less than forty years, undermined the foundations of all the religious systems in the world. We shall soon see that the Apostles were possessed of sound and candid minds, and that they only who resisted the conclusions resulting from their statements deserved the name of madmen.

We only propose to examine minutely the evidence for one of the miracles recorded in Scripture; but it is one of principal importance; for if it be false, none of the rest can be true; or if they be true, they are of no avail. We allude to the miracle of our Lord's resurrection, on which he stakes the credit of his pretensions and the truth of his religion. The Scribes and Pharisees said to him, "Master, we would see a sign from thee." But he answered and said unto them, "an evil and adulterous generation seeketh after a sign; and there shall no sign be given to it, but the sign of the prophet Jonas; for as Jonas was three days and three nights in the whale's belly, so shall the Son of man be three days and three nights in the heart of the earth." Mat. vii. 38, 39. On another occasion, the Jews said to him, "What sign showest thou unto us, seeing that thou dost these things?" Jesus answered and said unto them, "destroy this temple, and in three days I will raise it up." John ii. 18, 19. And to show what importance the apostle assigns to this miracle, he says, "If Christ be not risen, then is our preaching vain, and your faith is also vain." 1 Cor. xv. 14. If this miracle, then, be well ascertained, it renders all the rest credible, and may, indeed, be considered as the crowning evidence by which the truth of the gospel miracles and the gospel doctrines is attested.

There is reason to doubt if the best accredited facts in the history of the world be attested by such full and satisfactory evidence as the miracle of Christ's resurrection. It is seldom that we have the concurring testimony of four contemporary historians respecting any one event, of which they declare themselves eye-witnesses. The history of the world is not written in general by eye-witnesses, but by persons who have derived their information from various and uncertain sources; sometimes taken up from common report, or from documents which cannot be authenticated, and generally tinctured in its course by the imagination or prejudices of the writers and reporters. On these accounts a great degree of scepticism is allowable with regard to the commonly received history of the world. But should we meet with four ancient historians who declare that they had all been present during a war or a campaign, and who write accounts of the transactions agreeing in all essential particulars, and not positively contradicting each other in any, we would not hesitate for a moment to yield implicit credit to the general facts which they have recorded. But, if we except the account of the resurrection, and of the other occurrences in the life of our Lord, there is no event of ancient history which comes down to us thus attested.

We receive, with implicit confidence, Sallust's account of Cataline's conspiracy, because he was a contemporary, though not particularly engaged either on the one side or the other; we never entertain a doubt as to the events which occurred in the expedition of Cyrus, and the retreat of the ten thousand, because they are recorded by Xenophon who was present, and who conducted the retreat. We have no doubt whatever as to the exploits of Cæsar, because he himself recorded them; we scarcely allow ourselves to entertain the very natural suspicion that his statements may be distorted a little by self-partiality. We believe the short account which Eutropius gives of Julian's expedition against the Parthians and Persians, because he tells us that he himself served in that campaign. But in all these cases there is only one competent witness, on whose evidence we depend; and, generally speaking, we are sufficiently liberal in allowing its due weight to human testimony. We only ask the same candour to be extended to the history of the resurrection. This event is recorded by the four evangelists who saw and conversed with Jesus after his resurrection. Some have supposed that Luke ought to be excepted. But this is not certain; and his own words seem to imply the contrary: for he says he "had perfect understanding of all things from the very first." Here, then, are four authors writing separate and independent accounts of a wonderful event, of which they declare themselves to have been eye-witnesses; their statements as to time and circumstances agree in all material points; with such shades of difference, however, as prevent all suspicion of collusion or preconcerted design. Nobody can doubt that they were amply qualified as witnesses, from the opportunities of observation which they enjoyed; and there can be no possible reason for rejecting their evidence, unless some suspicion can be cast on their motives.

There are only two grounds on which suspicion can rest; it may be said either that they wished to deceive others, or that they themselves were deceived. Before we fix upon them a charge of desiring to impose upon the world, it will be but fair to show some reason for their entertaining such a design. That they had no such design must be apparent to every one who candidly examines their account. They all agree in declaring that Christ's resurrection was an event which they did not expect, and that they all doubted its reality after it was first announced to them. This is very unlike the language of impostors; it shows that they did not believe, or did not understand, the repeated intimations which their master had given respecting his resurrection. Had they been impostors and fabricated the accounts, the best way would certainly have been to set a bold face to the business at once, and to have declared that the resurrection of their master was an event which they had, from the first, confidently expected. But their declaration that they did not expect it corresponds exactly with the idea which they had formed of Christ's character and kingdom. They never allowed themselves to believe that he was to die, and, of course, they could not possibly understand the hints which he had given respecting his resurrection.

But it may be said that the disciples had motives of self-interest which induced them to frame and propagate the doctrine of Christ's resurrection. If this can be shown it must excite suspicion, if it does not amount to a valid objection. For it is not uncommon to see men advancing and obstinately maintaining the greatest absurdities and falsehoods, when they have an interest in doing so. Truth is then sacrificed to some supposed advantage. But amidst all the inconsistencies of human conduct we doubt if any man ever continued for any length of time to assert a falsehood, when it not only brought him no advantage but every possible inconvenience. A man who has told a lie once may persist in it for a while, for the sake of consistency, and to avoid the humiliation of confessing himself a liar. But let his interest lie on the other side; let his falsehood bring misery and contempt along with it, and he will soon be brought to his senses, and renounce an imposition so injurious to his own comfort.

Let us see whether this reasoning does not apply in its full force to the circumstances of the apostles and all the first witnesses of Christ's resurrection. What possible object could they have in persisting in an account so very improbable, had they not known that it was a truth of the most momentous importance which they were bound to promulgate to the world? They soon found that it had no tendency to promote their reputation, but rather to make them be laughed at as fools, as happened in the case of the apostle Paul when he preached the doctrine of Christ's resurrection to the philosophers at Athens. People, however, can bear to be laughed at when they gain any thing by it. But what were the disciples to gain by proclaiming the resurrection of their master? Not wealth and pleasures, surely; for they preached up abstinence and mortification: nor yet power and honours, for they knew, to use an expression employed by the most eminent among them, that they were counted "the off-scouring of all things." Here, then, we may justly say, is a marvellous thing, that so many men should persist in propagating a known falsehood without object or end—without interest or motive, and that they should daily expose themselves to insult, to persecution, and to death, solely for the purpose of propagating an unprofitable lie. Could we suppose all this possible, no parallel could be found to it in the annals of human folly, which are sufficiently pregnant with absurd materials. Yet scarcely will we find one man, much less great numbers of men, who will choose to be gratuitously wicked, and persist in a known falsehood, when it not only brings them no profit, but, on the contrary, subjects them to every conceivable disadvantage.

But we must be prepared for the other alternative, viz. that the first disciples were weak and enthusiastic men, and that they were themselves deceived, and became the dupes of their own delusions. And here, we will readily grant, that when once the mind is infected by any false doctrine or erroneous opinion, it is not easy to say to what lengths it may go in extravagance and folly. Hence we have seen men suffering for opinions which all the world but themselves knew to be false or pernicious. This is conceding as much as the adversaries of Christianity can require. But it will be of no avail to them. For it must be observed that all the great points on which our religion rests, and particularly the doctrine of Christ's resurrection, are not matters of *opinion:* they are *facts*, with regard to which even an enthusiast could not be mistaken. No stretch of imagination could make twelve men, nay, five hundred men (for by this number was our Lord seen after his resurrection), no stretch of imagination could make such a number believe that they saw Jesus alive, after he had been crucified, that he conversed with them familiarly for forty days, and then ascended into heaven in presence of them all. That there might be no room to suspect even the possibility of a mistake, he appeared to them on various occasions, and for a length of time, so as completely to satisfy the most scrupulous and incredulous among them, of the reality of an event so pleasing, but so unexpected. They do not disguise the pleasure and surprise which they felt on receiving the first authentic intelligence of the resurrection. "They believed not, for joy;" an expression struck from the mint of truth, and incapable of coming from the lips of a deceiver. They thought it was too good news to be true; and they felt that mixed sensation of joy, wonder, and incredulity, which overwhelms a depressed or wounded spirit, on the announcement of great and unexpected good fortune.

The apostle Paul enumerates several, though not all, of the occasions on which Christ appeared after his resurrection. He says that he was first "seen of Cephas, then of the twelve; after that he was seen of above five hundred brethren at once, of whom the greater part remain unto this present; but some are fallen asleep; after that he was seen of James, then of all the apostles; and last of all he was seen of me also, as of one born out of due time." 1 Cor. xv. 5—8. Now, were we even to admit the supposition of the infidel, that the first witnesses of the resurrection were enthusiasts, this admission would only tend to strengthen the evidence for the extraordinary fact; for an enthusiast is always an honest man; he may be deceived in a matter of opinion, but he has no wish to deceive others; and therefore when he attests, not the reveries of his fancy, but the objects which have come under the cognizance of his senses, he may be implicitly believed.

The amount of the argument, then, in so far as regards the motives of the first witnesses of Christ's resurrection, may be thus stated: if they had been impostors they would have had more sense, and more regard to their own interest, than to publish and persist in such an improbable and unprofitable doctrine: and if they had been enthusiasts, they would have had more honesty than to affirm as truth what they knew to be false; for a man cannot be an enthusiast, and at the same time a wilful deceiver.

But let us look for a moment to the features of the fact, as stated by the sacred historians, and not denied by the enemies of Christianity. The Jewish rulers were fully aware that our Lord had declared that he would rise again on the third day after his death.

We have already shown that the disciples could not understand this, because they could not allow themselves to think that the Messiah was to die. But the Jews, who had all along been bent on his death, had no such prejudices to obscure their conceptions. Judas, too, who had become their agent, and who had none of the views and feelings of the other apostles to prevent him from understanding the distinct intimations which our Lord gave of his resurrection, would doubtless put his employers in full possession of all these particulars; and they were not lost upon them; for they took the most judicious precautions to prevent an event which, if accomplished, they foresaw would render abortive all that they had done. The chief priests and Pharisees, therefore, went to Pilate, and said, "Sir, we remember that this deceiver said while he was yet alive, after three days I will rise again: command therefore that the sepulchre be made sure until the third day, lest his disciples come by night and steal him away, and say unto the people he is risen from the dead: so the last error shall be worse than the first." Pilate readily assented to their proposal; "so they went and made the sepulchre sure, sealing the stone and setting a watch."

Yet notwithstanding of all these precautions, the body of Christ did disappear on the third day, as the Jews themselves confess, and no infidel has been hardy enough to deny it. And how do they account for the circumstance? The only account they have ever attempted to give is, that the disciples came and stole away the body whilst the guard was asleep. If they could possibly have invented any other feasible story, or if falsehood could ever find a secure asylum, they never would have published an account so full of improbabilities and contradictions. For, in the first place, it is in the highest degree improbable that so many men as composed the guard (the number we do not exactly know, but we may be sure it was such as was deemed sufficient to defeat all attempts on the part of the disciples to carry off the body either by stratagem or force) should have all been so fast asleep as not to be awakened by the noise of persons rolling a large stone from the mouth of the sepulchre, and carrying a dead body through the midst of them. And, in the next place, consider who they are who give the account? The soldiers themselves were the only persons qualified to give any account of the business; but had the report which they circulated been true, they would have been the last persons in the world to confess a delinquency which they must have expiated by their lives. Besides, their account, like most falsehoods, contains in its bosom its own refutation; for if they were actually asleep, how could they know whether the disciples carried off the body or not? This could only be an inference; and, in the circumstances of the case, a very improbable one. For they who had universally forsaken their master when they foresaw his destruction, were not likely to risk much for him after he was actually dead. The evidence, then, stands thus, even on the admission of Jews and unbelievers; the resurrection of Christ is attested by hundreds who declare that they saw him frequently after that event, and with their eyes open, and all their senses in exercise; whilst the contrary statement, that the disciples stole away his body, is only attested by sleeping witnesses, who, in such circumstances, were certainly incapable of bearing testimony to any thing but their own dreams.

It may indeed be said, that the statement we have given rests on the authority of the apostles and evangelists. It does so; but it has never been contradicted, and it carries with it internal evidence of its truth. The Evangelist Matthew gives a most natural account of the whole transaction. He tells us that some of the guard ran instantly to the chief priests and told them all they had seen; upon this a council was held, and it was thought best not to make a show of punishing the soldiers for their supposed neglect, because they knew they would die declaring the truth. The council therefore agreed to bribe the soldiers; and they gave them, we are told, a large sum to induce them to propagate the unlikely story which we have been examining; and as they knew that the soldiers must do this at the peril of their lives, they said to them, "If this come to the governor's ears, we will persuade him and secure you," which they knew it would not be difficult to do, as Pilate could not be supposed to have any partiality for Christianity, though he was perfectly convinced of the innocence of its author. "So," the evangelist adds, "they took the money and did as they were taught; and this saying is commonly reported among the Jews till this day." That is, it was commonly said among the Jews at the time when Matthew's account was published, that our Lord's disciples took away his body when the guard was asleep. Thus the author, at the time he publishes his history, which was within thirty years of the time when the event happened, appeals to the whole country of Judea where his work was circulated, for the truth of what he stated as to the Jewish account of the resurrection. No author in his senses would have made such an appeal, had not this been the current edition of the story among the Jews; for every man living could have contradicted him, and such a palpable mis-statement would have offended the friends, and given every possible advantage to the enemies of Christianity. But the statement is not denied; it is the common account among unbelievers down to the present day; and we have endeavoured to show that it carries in its face falsehood and contradiction.

The grounds, then, on which we are authorized, or we may almost say compelled, to believe the doctrine of Christ's resurrection are these: it is attested by persons who had every opportunity of knowing the truth, and who had no inducement to tell a falsehood; and it is attested even by the enemies of Christianity, who, from the account which they have given of this transaction, show to the perfect satisfaction of every one capaple of distinguishing between truth and falsehood, that their account is fabulous, and that Christ is indeed "risen from the dead according to the Scriptures."

This doctrine, thus satisfactorily established, accounts completely for the zeal and for the success of the apostles and first preachers of Christianity, which, on any other view, must appear altogether inexplicable. We need not be surprised to see them devoting their whole lives, and sacrificing every consideration of ease and temporal convenience, in propagating the religion of him who was so visibly demonstrated to them to be the Lord's life, and the only hope of salvation; nor need we wonder that the doctrines of the cross, so different from any thing that had hitherto been known among men, should increase and flourish in the immediate hands of him who had preached it, for "healing to the nations." A candid examination of the success which attended the labours of the apostles cannot fail to make us recognise more clearly the power and wisdom of God in rendering such feeble instruments effectual in promoting such momentous consequences.

They tell us that they wrought miracles in the name of Christ, and that it was in consequence of the signs and wonders which God wrought by their hands that the Gentiles were turned to the knowledge of the truth. These were high pretensions; and it would have required more infatuation or effrontery than ever falls to the lot of any person of sound mind, to advance such claims in the very face of persons capaple of producing instant refutation, had they been unfounded. In the second epistle to the Corinthians, xii. 12, St. Paul says, "Truly the signs of an apostle were wrought among you in all patience, in signs and wonders, and mighty deeds." It is not in the power of human credulity to suppose that such a declaration would have been made, had it not been supported by truth. We can easily conceive that a man may boast, in one place, of fictitious exploits alleged to have been done in another. But was ever any braggart so senseless as to make the very people whom he wished to deceive, the judges of his impudence and lying vanity? No; such a supposition is belied by every feature of human nature; and therefore we may rest assured that the apostle appeals to events which no man could contradict.

But we dwell not any longer on a detail of evidence for the authenticity of the apostolic miracles; generally speaking, they rest on the same foundation with those performed by our Lord. We would only request attention to a few facts in the history of the Apostles which never have been, and never can be, disputed, viz. to the fact of unlearned fishermen converting the world, subduing the pride of philosophy, and resisting the efforts of power, till the princes of the earth were compelled to bend the knee before the cross of Christ; to the fact of such persons publishing doctrines which the ingenuity of learning never had been able to discover, and inculcating precepts for the regulation of life, far exceeding any thing that the wisest moralists or politicians had ever devised; to the facts of their blameless lives, of their disinterested labours, of their unwearied benevolence: grant but these facts, and you need no higher miracle, and no stronger confirmation that they were commissioned and taught of God; and these are facts which infidels themselves will not venture to dispute.

Such were the persons employed, and such the extraordinary result of their labours. Let us see whether we can discover the secret of their success in the nature of the means which they used. Did they owe their success to a more approved method of teaching than had usually been practised, to superior eloquence or more elaborate reasoning? Quite the reverse; they themselves boast that they did not attempt to inveigle converts by the enticing words of man's wisdom. 1 Cor. i. 17. Their doctrine was indeed pre-eminently distinguished by its importance, and its majestic simplicity: but these are not qualities with which the world is readily captivated, when separated from the accessaries of high birth, or eloquence, or fashionable opinion. The apostles had none of these advantages to recommend their doctrines. They derived no influence from their rank in society; none from the reputation of their learning; none from the obsequiousness and pliancy of their manners. They were stern moralists, inflexible advocates of truth, justice, and purity; intrepid reprovers of every deviation from integrity and virtue. Though in things indifferent they had sufficient liberality to "become all things to all men;" yet they were entirely unaccommodating and unbending with regard to every thing that had even the appearance of evil.

In all these respects the apostles were as opposite as can possibly be conceived to the character and conduct of those who seek pleasure or private advantage from the doctrine which they teach; for the doctrines of the gospel are not accommodated to a single failing, to a single prejudice, or to a single sinful propensity in human nature. They are addressed to the highest feelings, the sublimest conceptions, and the loftiest and purest hopes which the mind can entertain; and they never can be relished but by a heart emancipated from vulgar prejudices, and purified from mean and grovelling affections. They had to contend with the prepossessions of the Jews, which were the more inveterate from their being founded on mistaken interpretataions of the word of God; and with the learned pride of the Greeks, who had imposed their literature on the masters of the world, and scorned, of course, to be tutored by the despised nation of the Jews. In short, the general prejudices of human nature, and the local and natural prepossessions of every tribe and district, were all up in arms against the new and unwelcome doctrine, and against its unlearned and uncourtly teachers. Yet with all these disadvantages, the doctrine of the cross prevailed more and more, till the heathen temples were deserted, and the heathen rulers began to fear that the Christians might form a combination to overturn their power.

Now, although we had never heard of the apostles having wrought a single miracle, yet the plain facts which have been stated, and which have never been controverted, sufficiently demonstrate that the gospel was miraculously propagated, or that it stood by the power of God, which is all the miracle that we require.

Unbelievers have attempted to assign various secondary causes to account for the rapid progress of Christianity, without the necessity of a divine interference. Among other things, it has been alleged that the doctrine of the soul's immortality was taught so clearly by the first preachers, and is in itself so soothing and consolatory, that it excited immediate attention, and secured a ready reception to a religion in which it formed such a prominent feature. This very concession on the part of unbelievers furnishes an unanswerable argument against their system; for it admits that this important doctrine, which ought to form the basis of all religion, was very imperfectly understood before. How then did the uneducated teachers of the gospel obtain such clear views on a subject so important, and so remote from the ordinary conceptions of men? The most that the learned heathens could say on the subject was, that it was a comfortable creed, and that even though it were false, yet the belief of it was pleasant in the meantime, and could be attended with no disagreeable after consequences. Certainly our Lord and his disciples took up a very different ground. They made the doctrine of a future state the *primum mobile* of life, and taught mankind to consider every thing as subservient to this great end. But before this doctrine can be regarded as an attractive one, we must consider what is implied in it, as enforced by the preaching Christ and his apostles. According to their statement, it is a doctrine that can be consolatory only to the righteous; that is, to those who receive the faith of the gospel and exhibit its fruits in their lives; but it is the most terrible doctrine that ever was preached to the wicked and disobedient; for it declares that they "shall be punished with everlasting destruction from the presence of the Lord, and the glory of his power." Unless it could be shown that the gospel holds out the blessings of eternal life indiscriminately to all, it could have no attractions to the wicked, who always form the majority; and could it be shown to have such a tendency, the righteous would have reason to reject it as derogatory to the nature of God and subversive of his government.

It is indeed said in our translation that "Jesus Christ brought life and immortality to light." The word here translated immortality (αφθαρσιαν) should be translated "incorruption," as is done 1 Cor. xv. 53, and elsewhere; and then it must be understood as relating to that spiritual incorruptible life which can be enjoyed only by "the pure in spirit" in the kingdom of heaven. In fact, the doctrine of "eternal life," taught in the gospel applies solely to the principles of the spiritual and divine life, which are planted in the soul in the present world, and which being perfected by the varied discipline of life and dispensations of providence, is at last ripened into complete holiness and bliss in the kingdom of God.

This was a doctrine which formed no article in the creed of the heathens. Their idea of immortality merely implied the continuance of existence, and the enjoyment of the same pleasures and pursuits in which they had been engaged in the present world. Their Elysium was much the same as the Mahometan paradise. But the "eternal life" of Scripture is entirely the reverse of all this, so far as regards sensual enjoyments. In the Christian heaven there is no hunger nor thirst, no marrying nor giving in marriage, none of those relative ties which constitute the duties and happiness of society in the present world, and no feeling can be admitted there except those spiritual and divine habits which have been engrafted in the soul from the admiration and imitation of the divine perfections.

Another misrepresentation has been advanced with a view to exclude divine influence from the propagation of the gospel, and to account for its success from common and secondary causes. It is alleged that it takes responsibility from man; and relieves him of much trouble, by teaching him to depend on the merits of another; and that a religion characterized by such features, could not but be acceptable to the indolence of human nature.

This is either ignorant or malicious misrepresentation. All that the gospel inculcates respecting the necessity of divine influence, and the aids of the Holy Spirit, is intended to stimulate, not to relax our exertions. "Work out your salvation with fear and trembling; for it is God which worketh in you both to will and to do of his good pleasure." Philip. ii. 12, 13. Here the operation of the Spirit of God, who works in us to will and to do of his good pleasure, is stated as an inducement to work out our salvation with fear and trembling: and it certainly is a powerful argument for exertion when we reflect that every virtuous emotion proceeds from the Spirit of God, who promises his assistance, and calls us to be labourers together with him in the great work of salvation. At the same time this consideration may well inspire us with fear, lest we should have received so much of the grace of God in vain, and lest we be found wanting in the due improvement of the ample means and assistance with which he has furnished us. All the exhortations of the gospel correspond with this representation; hence we are called on to watch and to pray, and to be active and diligent in the use of those means which God has appointed and promised to bless for our edification.

And with regard to the other objection that the gospel found a ready reception, because it pointed out an easy method of salvation by teaching men to rely on the merits of another, we may safely say that human nature must be greatly changed from what it was, if this view of Christianity proved a recommendation to it. It is not commonly found that any thing which tends to sink human merit will meet with a ready reception among men; and we believe that the greatest object to the gospel has always arisen from the low estimate which it forms of human virtue; and from its representing the best services of men as unprofitable in the sight of God. There is nothing that men will not do sooner than believe this. They will give their bodies to be burnt, or to be torn in pieces by every conceivable torment, if any person can persuade them that heaven may be won by such sacrifices. And it is not difficult to produce such a conviction: it is a deep rooted prejudice of the human heart: it is a wrong conclusion drawn from just and natural premises; it is founded on the feeling of responsibility, on the consciousness of guilt, and on the persuasion that some extraordinary sacrifice is necessary to procure expiation. But along with these feelings and convictions, which might naturally enough lead to humiliation, there is a principle of pride no less firmly rooted in the mind of man, which teaches him to believe that the expiation may be made by his own efforts, and that his personal sufferings and privations will have merit to atone for any sin.

This notion lies at the foundation of all the superstitions of polytheism; and the bodily sufferings and voluntary inflictions which were so profusely exhibited, were the result of pride rather than of humility. The infatuated visionary was attempting to take heaven by force, and to establish his claim to salvation, as a debt and not as a favour. The doctrines of Christianity are the reverse of all this in every point of view, and, therefore, it must have been an objection to them that they opposed such inveterate prejudices of the human mind. So much was the Church of Rome aware of this, that to remove all objections to its external sovereignty, the only object which, as a church, it ever had in view, it laid hold of those very prejudices which Christianity had exploded, and revived the claims of human merit by prescribing certain penances and bodily services as available to salvation.

From these facts, any one may judge how far the gospel owes its success to the conformity of its doctrines with the common notions and prevailing feelings of the human mind. It is, indeed, one of the singularities attending its dissemination, that it forced its way in the world, in spite of the most formidable obstacles arising from the sins which custom had licensed, and from the prejudices which superstition had consecrated in the human mind. This is in itself sufficient evidence that "God gave *visible* testimony to the word of his grace" when he enabled the first preachers of the gospel to triumph over obstacles, which, in modern times, resist all the powers of learning, of eloquence, and of argument. And should any one feel disposed to regret that the same signal success does not attend the labours of modern missionaries, who are much better qualified, in point of literary attainments, than the apostles were, we would remind them that this very circumstance is one of the most decided proofs of the divine origin of our religion. Were it immediately received, we might be apt to suspect that there was nothing peculiar in it; and were the labours of modern missionaries, who do not pretend to miracles, as successful as those of the apostles, there could be no reason for bringing in the visible power of God in behalf of the first preachers of Christianity. The many remarkable failures which we have witnessed, are proofs that the rapid success of the apostles was chiefly owing to visible interpositions of divine power; and that the want of this extraordinary aid is the cause of the slow progress of Christianity in modern times. But these failures, instead of discouraging, should animate our efforts; as they afford a demonstration that God himself originally established that religion which he commanded his servants to carry to the remotest corners of the earth; and we need never despair of a blessing on a work which God himself has countenanced, and which he has hitherto distinguished by his special support against all the attacks of unbelievers.

But there is another species of evidence adduced in favour of Christianity, which, as contra-distingished from the evidence of testimony and facts, has been denominated *internal*, and is founded chiefly on the adaptation of the gospel to the wants and circumstances of men; on its excellence as a rule of practice, as a source of knowledge, and as a ground of hope and of consolation; and it is argued that a religion which has so many marked characteristics of benevolence and wisdom can have no other than a divine origin. We are disposed to consider the arguments connected with this view of the subject, as, of all others, the most conclusive. Indeed there is, properly speaking, no Christianity, till those convictions of its power and efficacy are produced in the mind; they constitute the sum and substance of practical Christianity, and therefore they are to be considered as results, rather than as evidences: as consummations of Christian faith, rather than as steps in the arguments which lead to it. A man's conviction is already complete by the time he feels that the gospel has enlightened his mind, reformed his practice, confirmed his hopes, and removed his fears. He has then, as it is expressed in Scripture, "the witness in himself," 1 John, v. 10, his conscience, feelings, and all his faculties yielding a ready assent to the value and importance of the Christian revelation.

But it would be needless for a Christian to tell an unbeliever what he feels on these subjects. One man's feelings can be no argument to another: and the unbeliever will take his stand exactly on the same ground, and will say, that he rejects the gospel, because it is revolting to his feelings, and because he is persuaded that the adoption of it would mar his happiness. Here then, we shall suppose, is the point with regard to which the two parties are at issue, the one maintaining that the gospel promotes human happiness, the other that it destroys it. Are there no *data*, then, by which this controversy can be decided? Is there no standard to which we can refer on a point so deeply interesting to human nature? To maintain that there is not, would be to confound reason with prejudice, to renounce as fallacious every intimation of conscience, and to dismiss as insufficient every principle which enables us to judge of the consequences of actions.

Is the gospel, then, or is it not, friendly to human happiness? If a verdict shall be returned in its favour, it will be entitled to the support of all who hold that happiness is "our being's end and aim." At the first view, its aspect is not alluring: but it will be an argument in its favour, if it can be shown to be friendly in its intentions. Its doctrines and its precepts stand as antagonists to all those propensities which are nourished by excess, and by inordinate love of the world: but this will not operate to its disadvantage, if it can be shown that nothing less than the self-denial which it enjoins can prevent us from being suicides of our own happiness; and that unrestrained indulgence is the sure road to disgrace and misery. It is quite common to hear it said, how can a religion which professes to come from heaven, be so opposite to the propensities of human nature? Can the same God give opposite intimations, and, at the same instant, impel to gratification and forbid it? This apparent anomaly does not originate in the gospel: it has its foundation in the nature of man, which supplies, at the same time, both a stimulus and a check to gratification. On the one hand, we feel a decided love of pleasure, whilst on the other, conscience interferes to prevent the unlawful indulgence of it; and the ardour of gratification is checked by the failing powers of nature, and by the languor or disease which excess produces.

It is obvious, then, that there are very contradictory principles in our nature; we are prone to excess, and reluctant of restraint, yet we are compelled to attend to the voice of conscience which points out the boundaries which we ought to respect, and warns us of the danger which attends transgression. It is farther obvious, even without the light of Christianity, that man rises in the scale of moral excellence, of public usefulness and private happiness, in proportion as he resists the undue indulgence of the mere animal propensities, and obeys the moral feelings of his nature: whilst the man who degrades himself by brute enjoyments, necessarily forfeits rational happiness, the esteem of his fellow creatures, and the hopes of a better world. These are axioms recognised by all nations whose names have not sunk into oblivion, by neglecting the conduct which results from them. Is it not, then, highly in favour of Christianity, that it takes a decided part with these better principles of our nature, that it labours to strengthen conscience, to promote justice, to banish selfishness, to increase universal benevolence? And if it can be shown that the gospel promotes all these objects infinitely better than any other system, and supplies motives and inducements far beyond what any man, or set of men, ever devised, we shall have, in that case, a strong presumptive evidence of its divine origin; and this presumption must amount to certainty, when we consider the men by whom it was first announced, and the circumstances in which it was first propagated.

But let us view the subject a little more narrowly in its general complexion and structure, and see whether we cannot discern the symptoms of an origin infinitely more exalted than any other system of morals or religion can justly claim. And here let it be observed, that all the ancient systems of morality and religion laid claim to a divine origin, and we have the names recorded of the gods, or inspired legislators, who established them. It is long since the world has been satisfied of the futility of these pretensions, and the systems founded upon them have been abandoned as inconsistent with the light of reason and with some of the best interests of man. They either permitted what was hurtful, or forbade what was innocent; and the consequence was, that they exhibited the contradictory extremes of profligacy and licentiousness on the one hand, and of the most revolting violations of nature, and of nature's feelings on the other.

All religions, but that of Christ, are chargeable with these defects and improprieties. It prescribes no self-denial, except with regard to sinful lusts; no mortification except of evil affections; it gives full scope to every feeling that contributes to the real enjoyment of life, whilst it guards, by the most awful sanctions, every duty, the observance of which is necessary for our present and future happiness. It extends our views far beyond the limits of this world; it confirms those anxious anticipations and eager desires of immortality which the mind has, at all times, so fondly cherished; and these being established, and the future life of man being shown to depend on his present conduct, as mankind have always believed, the gospel, in conformity to this leading doctrine, tells us, that every action of our lives should have a reference to immortality, and that it will profit a man nothing to gain the whole world and lose his soul. This is the necessary conclusion arising from a universally received doctrine; and it is here that the excellence of the gospel is particularly manifest, for it does not tell us that earth and heaven are absolutely opposed to each other, or that we cannot discharge a conscientious duty to both, or that we must be miserable here in order to be happy hereafter. It warns us, indeed, of the danger of undue attachment to the world, as tending to check every spiritual aspiration, and to make us unmindful of our best hopes; but whilst it prescribes rules which have for their ultimate, and apparently their only object, the eternal interests of the human soul, it is found that the observance of these rules promotes our present happiness more effectually than if we had nothing else in view; and we learn from experience, that "godliness is profitable unto all things, having the promise both of the life that now is and of that which is to come."

An unbeliever will perhaps be inclined to dispute this statement, and in particular to deny the influence of Christianity in promoting present happiness. We appeal to the bar of reason and conscience, and promise to abide by their decision, even with regard to the most obnoxious precepts of the gospel. Take *humility*, that characteristic feature of Christianity, for an example. The author of our religion says, "Learn of me, for I am meek and lowly, and ye shall find rest to your souls." With regard to this injunction, which the unchristian mind must necessarily dislike, the question simply is, whether a man is most likely to find rest to his soul, by humbling himself, or by endeavouring to humble others; in the latter attempt he will never be completely successful; he will always find some to resist his claims, or dispute his pretensions: and he will always suffer under the feelings of wounded pride and disappointed ambition. It will be alleged that humility is only the property of a low, unmanly spirit, and that it must destroy the dignity and energy of the human character. No one will think so who remembers that this humility arises solely out of the relation in which the Christian feels himself to stand with regard to God, and not from any fear or great reverence which he entertains for man. He who thinks humbly of himself from a consideration of the divine majesty, will be in no danger of thinking too highly of others; he will form a just estimate of them, and will perceive that he ought to regard them with feelings of charity and brotherly love, rather than with fear or idolatrous veneration.

We have seen how nobly this quality was exemplified in the conduct of the apostles. They were distinguished by patience, meekness, and humility; but they were distinguished no less by undaunted fortitude and unparalleled intrepidity. Though born and brought up in the humblest stations of life, they were not confounded when they were called before princes and rulers. Paul had the boldness to arraign the very vices for which Felix was notorious, and the profligate governor trembled in the presence of the man who was brought as a prisoner before his tribunal.

Here, then, is one singular quality enjoined by Christianity, to which the natural mind feels a repugnance, but which reason can demonstrate to be perfectly consistent with the dignity and happiness of man, and to be, in fact the best means of promoting both. And it is one of those moral qualities, more, perhaps, than any other peculiar to the gospel. There is no word in the classical languages of Greece and Rome to denote the virtue of humility. It is a quality, however, which results so naturally out of the relation in which man stands to his Maker, that the religion which so forcibly enjoins it may be said to have a sign from heaven, that it proceeds from God; whilst those which encourage opposite qualities betray themselves to be of earthly origin and of human invention.

Take another quality, the forgiveness of injuries, which, if not absolutely peculiar to the gospel, is at least enforced by it with a clearness, and with a strength of motive not to be found in any other system of religion or morals. "Forgive thine enemies," says a heathen, "for by returning their injuries thou art only equal with them, by forgiving them thou art superior." This is very fair reasoning; but we may justly doubt whether it would produce any very decided effect. The precept of the gospel, however, goes much farther, and is enforced by much more powerful motives. "Love your enemies, bless them that curse you, do good to them that hate you, and pray for them that despitefully use you and persecute you." This is stretching the precept, it may be thought, to the very verge of human endurance; yet it is nothing more than the fair result and legitimate conclusion of the principle by which our Lord recommends it, which is, "That ye may be the children of your father who is in heaven, for he maketh his sun to rise on the evil and on the good, and sendeth rain on the just and on the unjust." Mat. v. 44, 45. Was any such motive ever suggested by any other teacher? Was man ever authorized to contemplate such an exalted origin, or called upon to imitate such a spotless pattern? Nothing like it is to be found in the records of human wisdom. We see ourselves placed in the most intimate union with God, and, as his children, we are called upon to imitate his perfections, the most conspicuous of which are mercy and forgiveness.

Let us now see, then, whether we discover in the gospel such marks and characters as must necessarily belong to a religion which comes from heaven. Such a religion must explain and exalt the divine perfections; must make us better acquainted with the nature and government of God, whose being is universally admitted, but whose character is, in general, very imperfectly understood; must be distinguished by wisdom and benevolence; must tend to promote the best interests of man for time and for eternity; and all these marks are to be found in the gospel of Christ, or they are to be found nowhere. It has, at least, annihilated the claims of every other religion, and if any one should entertain a suspicion that it may still mislead us, we can only say, that if it does, there can henceforth be no confidence in human reason, no dependence on human testimony, and no trust even in miraculous appearances: for in all these respects every thing that the mind can require to satisfy its doubts has been most amply supplied; and we do not think it possible for the present faculties of man to receive any fuller demonstration of the truth of Christianity than is set before us in the authentic facts on which it rests, and the intrinsic excellence by which it is distinguished.

It may appear matter of astonishment that a religion so attested, and so obviously calculated to promote the best interests of man, should nevertheless be so obstinately resisted. This, which might appear singular, is resolved into a prominent feature of human nature by our Lord's words, "Whoso doeth evil hateth the light, neither cometh to the light, lest his deeds be reproved." If the view which has been given of human nature be correct, if it be earthly and sensual in its original tendencies, averse to restraint, and prone to excessive gratification, in these circumstances opposition to the gospel is exactly what we may expect, and is an additional internal evidence of its divine origin. A religion perfectly accommodated to the natural feelings, or falling in with the prevailing propensities of human nature, would need no other evidence to prove that it could not be divine. For who can doubt that the prominent features of the human character, before it is refined and exalted by moral culture and religious principle, are pride and ambition, selfishness and sensuality, qualities which can never be countenanced by a divine religion, and which must be subdued before such a religion can be relished by the human mind.

It is common enough to hear it said by professed friends of Christianity, that it is congenial to human nature; and so it is when once the heart adopts its precepts; its yoke is then felt to be easy and its burden light. But there must be many a struggle and many a sacrifice before this surrender of the heart is made; and whilst we would recommend the gospel as in the highest degree calculated to promote the happiness of man, we would wish it, at the same time, to be remembered, that it is only accommodated to our real wants, but not to our misjudging wishes; that it promotes our real dignity, whilst it lays prostrate in the dust our imaginary consequence; and that it advances our best interests for time and for eternity, by opposing many of our decided inclinations.

It is a proof, then, that the gospel is heavenly, when we see it so obstinately resisted by the sinful feelings of men; and in every instance where it has ultimately been rejected, the reason may be found in some depraved affection, or some sinful bias of the human heart. It is the intimate and indissoluble union between the doctrines and the practical precepts of the gospel—the inseparable connexion between faith and holiness, that appears so formidable to the indolence and inveterate prejudices of men. It is not the abstract creed of Christianity that gives offence. Men are by no means nice as to their creed; there is no absurdity too monstrous for them to swallow; and Christianity, when degraded to the rank of a superstition, and disjoined from its influence on life and morals, is as popular as any other, and will as readily obtain proselytes. This was proved by the success of the Romish missionaries, one* of whom tells us that his arms were completely tired with baptizing the immense

* St. Francis Xavier.

multitudes of heathens who flocked to conversion in one day. If the gospel were satisfied with such converts, we do not believe there would be any difficulty of christianizing in a short time the whole world. For no religion can come forward with such pretensions as Christianity; and were it not so intimately connected with the heart and the conduct, it would soon become the dominant religion throughout the world.

It is not the fault of Christianity, then, that it is not more readily and more extensively received. It has a work to accomplish on the mind of every individual, which is in direct opposition to confirmed habits and preconceived opinions; and the transformation of character which it effects cannot be brought about without resistance on the part of our natural feelings. One great design of the gospel is to "bring the whole man into subjection to the obedience of Christ," that is, to emancipate the mind from the dominion of ignorance, prejudice, and sin, and to substitute in its place the sovereignty of reason, knowledge, and virtue, as embodied in the law of God. Who can doubt that such a change is desirable, and that it should be the object of a divine religion to attempt to accomplish it? And who is so ignorant of human nature as to suppose that this change can be effected without a struggle? The gospel, then, bears in its face one distinct feature of divinity, in being opposed to all the sinful, and degrading, and mischief-working propensities of human nature.

It will probably be alleged that, according to this reasoning, there are insuperable obstacles to the general reception of the gospel, in the very principles of human nature. To this we would answer, that the observations which have been made apply chiefly to ripened sinners, to those whose natural propensities have not been checked by early culture, and who have been allowed to grow up in antichristian habits and feelings. Even with regard to these, though their conversion be difficult, it is not impossible. They are in the situation in which all heathen nations have been when the gospel was first announced to them, and their prejudices, however strong, are not invincible. But we can easily conceive a situation in which these unfavourable symptoms may, in a great measure, disappear; and that situation will occur, when Christian discipline, judicious education, and good example, are all brought to operate on the youthful mind, and are employed to train it from the very first evolution of its feelings, to Christian habits and sound knowledge. The visible opposition to the gospel will then vanish, because the principles on which that opposition is founded, have been crushed before they acquired ungovernable strength, and because the mind has been made familiar with the enlightened doctrines and useful tendency of Christianity.

The internal evidence for the divine origin of Christianity which has hitherto been adduced, is founded on the wisdom and utility of its instructions as connected with the history and the hopes of man. And, in fact, every argument produced to show the reasonableness of any of the doctrines of Christianity, is to be considered in the light of an internal evidence in its behalf. But there is an extensive class of arguments of this description arising neither from the doctrines nor from the precepts of Christianity, but from circumstances connected with its history. The low and suffering condition of Christ, for instance, is in perfect consistency with what is stated to be the great end of his mission, viz. to lay down his life a ransom for many. Had he appeared in the splendour of regal dignity, and maintained throughout a state corresponding to it, the great consummation of his death could not have happened. The same circumstances would have disqualified him for a teacher, and for an example to suffering mortals. As nothing is of so much consequence to us as to be taught to endure the ills of life with patience, fortitude, and hope, so we find that he who is set forth as the hope of Israel, and of all nations, was placed in exactly such circumstances as best qualified him for giving us useful lessons of faith, fortitude, and resignation. Had he lived respected, and died renowned, he could not have shown us the efficacy of Christian faith, in supporting the heart amidst the severest trials, and in realizing to us the hope of a better world. His doctrine was, "fear not them who can kill the body;" or in other words, hold fast integrity and a good conscience, though at the expense of life itself: and he illustrated the precept by his example. No degree of suffering could make him swerve from his purpose, or relinquish his feelings of benevolence and love to the human race. Since, then, man is born to sorrow, is it not a proof of wisdom and goodness on the part of God that "the Captain of our salvation was made perfect through suffering?" It was this condition alone that perfected him as a teacher, as an example, and as a propitiation.

Here, then, all the parts of this extraordinary scheme hang rightly together; and we may add its perfect consistency as a farther recommendation to our acceptance of it, as a plan devised by God.

Some have alleged that we know so little of the nature of God, that it is presumptuous in us to say what kind of revelation he might be expected to give, and of course all arguments founded on *internal evidence*, which go, in effect, to measure the ways of God by our conceptions of fitness, must be precarious or fallacious. We do not assent to this conclusion. We do not say what kind of revelation God *might* have given; we only presume to judge of that which he *has* given. It appears that some of the wiser heathens were led to expect, or, at least, to desire a revelation. They judged it necessary on account of the hopeless ignorance of men. Had they speculated on the nature of that revelation, we may be perfectly certain that they never would have anticipated that which was actually given. It rested on deeper principles than the light of nature could discover. But this does not prevent us from passing a judgment respecting it, now that it is known; and the beauty and excellence of the Christian revelation is this, that it has not fettered but improved our faculties, and made them capable of passing a decision on its adaptation to the wants and circumstances of men.

There is not one precept, and scarcely one doctrine of the gospel, that does not rest on other grounds than mere authority. As the Almighty requires of us a reasonable service, he suggests reasonable motives for the performance of it, and has made us capable of discerning that his demands are not founded in wanton despotism, but in the tenderest regard to the happiness and improvement of his creatures. Admit but this, and who can doubt the competency of human reason to pronounce on the nature and tendency of a scheme professing to come from God? It may be said that the miracles performed are sufficient to command our assent to the doctrines which they were wrought to inculcate, although we should be totally unable to understand them. But how few doctrines are there of this kind in the Christian revelation? We believe there are none but the divinity of Christ, and his appointment to redeem mankind. These points could not be established by reasoning; they lie beyond the sphere of its natural operations. But these points being established by the power which the Saviour possessed, they become proper subjects of reasoning; and we are entitled to inquire whether there is any thing in them contradictory to the general analogy of nature, to the known character of God, as manifested in his works, or to the ordinary course of his providence. And if we shall find that there is here no contradiction, but, on the contrary, a beautiful harmony and additional illustrations of the divine nature and government, extending, connecting, and methodizing our knowledge, we have then *internal* proofs that the doctrine is from God. Here, as in every other instance, the revelation itself supplies the means of judging of its nature and character; and we have so much the greater reason to conclude it to be from God, when it furnishes the most important information in a way that the mind of man would not have devised.

We are far from presuming to say that the mysteries of heaven must be made obvious to our apprehension. These mysteries we are bound to believe when established by unequivocal miracles. But a miracle never was displayed to establish a mystery unconnected with the life and hopes of a Christian. The most mysterious parts of the Christian creed have a direct bearing on faith and practice. The Trinity, for instance, forms an essential article of belief; for without it we could have no idea of the Father who sends, of the Son who saves, and of the Holy Ghost who sanctifies. In short, no mystery is revealed in Scripture but what is intended to have an influence on the faith, and consequently on the duties and the hopes of men. On these latter points we can judge; and if a doctrine were announced, as enjoined by heaven, but which is found to contradict the first principles of reason, and to militate directly against human happiness, we might justly hesitate about admitting its truth, even though miracles were wrought to support it. What we mean to affirm is this; that even a miracle could not establish a general principle at open variance with those clear intimations arising from the light of conscience and reason, and from the visible ordinations of providence. The evidence could not be stronger on the one side than on the other; and the result could only be an entire suspension of our faith on the point in question; as the means of determining would be utterly destroyed by the contradictory intimations of our senses and our reason.

It is clear, then, that we are compelled to judge of every doctrine by its general tendency, as much as by the authority with which it is enforced. A miracle shows the power of the legislator; but we judge of his wisdom or his goodness by the nature of his enactments: and the beauty and excellence of the Christian dispensation consist in this, that its most peculiar doctrines are such as our reason is compelled to approve, though it would never have been able to discover them. We have thus a double security for our faith; for on the one hand we see it enforced by a power which no man can with safety resist: whilst on the other it is recommended by such distinct features of beneficence and wisdom as must secure both the love and approbation of every reasonable mind. Were miracles wrought to enforce maxims hurtful to human happiness, it would be a mere tyrannical display of power, at which the heart would revolt. But when we see that power is manifested to secure obedience to laws framed for our own good, we admire both the wisdom and condescension of the lawgiver, and we then love and revere a power which is exercised only to secure our own happiness.

Some of the friends of Christianity seem to have conceived a prejudice against the *internal* evidence for its divine origin, chiefly, we believe, because this is the point which infidels have principally contested, and on which they profess to build their opposition. The evidence of miracles remained almost unquestioned till it was assailed by the flimsy sophism of Hume, which would long ere now have been forgotten, had it not been preserved from oblivion, by being embodied in the beautiful refutation of Campbell. The evidence of prophecy, too, has been in a great measure unmolested; the only relevant objection that unbelievers have urged being, that the prophecies were written after the events which they pretend to predict; an objection so shallow and untenable, that to mention it is a sufficient refutation. But unbelievers have adopted a mode of warfare which has often been successfully practised by a skilful enemy; they have left the strong holds unmolested, and have directed all their efforts against the troops who keep the field, being well assured that when these are completely routed, and unable to appear, the strong places must quickly fall. In other words, they have attacked the substantial doctrines and distinguishing precepts of Christianity, under the impression, which we believe to be well founded, that if they can get the better of these, the external evidence will soon go for nothing.

And shall we decline to meet them on this field? Shall we post ourselves behind our bulwarks, contenting ourselves with bidding defiance to our enemies, whilst they are allowed to ravage the country, and harass its population? Such conduct would be cowardly, and unworthy of the high cause which we profess to advocate. Whilst, then, we should avoid the presumption of demanding that the mysteries of God should be brought down to the level of our understanding, a demand which reason itself must pronounce to be unreasonable, and impossible to be complied with; yet we may confidently affirm, that no doctrine is revealed in Scripture inconsistent with the dictates of enlightened reason: on the contrary, they are all recommended by their obvious congruity with some principles which reason recognises as ultimate and incontrovertible.

Hitherto we have applied this mode of illustration only to the precepts and moral instructions of the gospel, and have endeavoured to show that even when they oppose our feelings, they promote our happiness, and are approved by our reason. These precepts are not so much distinguished by the novelty of the qualities which they enjoin, (for they are, in general, founded on the broad basis of human nature,) as by the novelty of the sanctions by which they are enforced, and by the strong unqualified terms in which they are delivered.

This is a striking peculiarity in our Lord's manner as a moral teacher. He does not attempt to win assent by slow and cautious advances on our prejudices; he assails them at once, and rouses their utmost opposition by the decided and unqualified nature of his attack. When he wishes to discourage vindictive feelings, and prevent men from taking into their own hands the adjustment of their own wrongs, he does not proceed on the principles of political morality, to show that such practices would be injurious to the state; but he says in language alike calculated to astonish and offend, "Whoever shall smite thee on thy right cheek turn to him the other also." Mat. v. 30. His object was to arouse the attention to a momentous truth; and he clogs the precept with no deduction or qualification, knowing that men would soon be ingenious enough to discover these for themselves. To show the dangerous tendency of riches, he does not stop to point out the temptations to which they lead, or to warn mankind against their gradual influence in deteriorating the character, but he says in language, which no man, whether rich or poor, can ever forget, "It is easier for a camel to go through the eye of a needle, than for a rich man to enter the kingdom of heaven." Such a declaration, proceeding from an authoritative teacher, must have roused the most languid attention: even his disciples, we are told, "were exceedingly amazed;" this was what was intended; it would excite discussion among those who heard it; and, on due examination, it would be found to be the converse of that salutary proposition, that none but the "poor in spirit," shall inherit the kingdom of God; and that they who are only rich as to this world, shall never taste the blessedness of heaven.

This peculiarity is not to be found in other moral teachers, who are compelled to employ every artifice to seduce men into their conclusions. But Christ "taught with authority," inasmuch as he laid down the rule, without stating the reasons on which it was founded, which no other teacher had ventured to dispense with; and which even he would not have neglected had he not possessed other means of securing attention; and had he not seen that the reasonableness of his precepts would ultimately sustain them.

The want, then, of the usual processes of reasoning in bringing out moral deductions, is a proof that our Lord had other means of giving them efficacy; whilst the excellence of the maxims, which must be obvious when they are subjected to candid examination, shows how little despotism there is in divine enactments, and that they are addressed to our reason, our conscience, and our best interests.

In this article we have endeavoured to give a comprehensive view of the foundation on which true theology rests; and we have gone so far beyond the outworks, as to adduce many of the peculiar doctrines and precepts contained in the Scriptures, as illustrative of the divine origin of the record in which they are contained, and proclaiming, at the same time, their own high authority and the reverence which is due to them. We had intended to give a view of *polemical* Theology, and a catalogue of the books most useful for the Theological student; but the limits prescribed to this article prevent us from entering on the wide and thorny field of polemical Divinity; and it would have been necessary to append so many qualifications to every book that we recommended, that this undertaking would itself have formed a volume. We, therefore, only recommend, as of unquestionable utility, the earnest study of the sacred Scriptures, in the original languages; and perhaps the best commentaries on them will be found in the various translations which different Christian churches and communities have given of the original Scriptures.

THEOPHRASTUS, a celebrated Greek philosopher, and the pupil of Aristotle, was born at Eresium in Lesbos B.C. 371. He died B.C. 276, at the age of 85. His principal works are his *Characters*, and his *History of Plants*. Among the best editions of the first are those of Isaac Casaubon, of Needham, with the notes of Duport, Cantab. 1712, and of Fischer, Coburg, 1763. The most complete edition of his History of Plants, is that of Budæus, in Greek and Latin, Amstelod. fol. 1644. The last edition of his whole works is that of Heinsius, Greek and Latin, folio, Lugd. Bat. 1613.

THERMO-ELECTRICITY.

THERMO-ELECTRICITY is a term introduced a few years ago into natural philosophy, to signify the electrical current, excited in a circuit of conductors, when the equilibrium of its heat is disturbed in such a manner as to cause therein a circulation of caloric.

Thermo-electricity being a particular branch of *Electromagnetism*, which has been discovered since the publication of the volume of this work in which it ought to have been treated, it will be necessary to comprehend the whole doctrine of electromagnetism in the present article.

HISTORY.

In the earliest period of the history of magnetism and electricity, the minds of philosophers were more struck by the resemblances of these two agencies than by their disparities. The first philosopher who undertook a regular series of comparative experiments upon magnetism and electricity, was the celebrated Dr. William Gilbert, who first published his inquiries in the year 1600. He was aware of so many disparities between them, that he declared their resemblance to be merely accidental. He had indeed strong reasons to think so at that time, for the magnetical polarity was well known to him, and principally by his own experiments, but the discovery of the electrical polarity was reserved for a philosopher of the following century (du Fay). This discovery, and particularly the fundamental law of electrical polarity, brought forward by Franklin, again countenanced the opinion of the resemblance of electrical and magnetical powers; and the sagacity of *Æpinus* gave great credit to it. But immediately after this acknowledgment of their resemblance, another excellent philosopher, *Van Swinden*, was struck with the disparities which remained still unexplained, and his ingenious inquiries obtained much approbation. The discoveries of *Galvani* and *Volta*, by which the electrical powers were exhibited in forms very different from those formerly known, gave the opinions upon this subject a new turn. The German philosopher, *Joh. Will. Ritter*, was thought during some time to have produced magnetical effects by the Voltaic pile, but his experiment having been repeated without success, the subject remained as it was. Thus the balance inclined alternately sometimes to the one, and sometimes to the other side; but at no time have either of these opinions met with general reception. A certain turn of mind has here, as in most other controversial doctrines, exercised a considerable influence. One class of natural philosophers have always a tendency to combine the phenomena and to discover their analogies; another class, on the contrary, employ all their efforts in showing the disparities of things. Both tendencies are necessary for the perfection of science, the one for its progress, the other for its correctness. The philosophers of the first of these classes are guided by the sense of unity throughout nature; the philosophers of the second have their minds more directed towards the certainty of our knowledge. The one are absorbed in search of principles, and neglect often the peculiarities, and not seldom the strictness of demonstrations; the other considers the science only as the investigation of facts, but in their laudable zeal they often lose sight of the harmony of the whole, which is the character of truth. Those who look for the stamp of divinity on every thing around them, consider the opposite pursuits as ignoble and even as irreligious; while those who are engaged in the search after truth, look upon the other as unphilosophical enthusiasts, and perhaps as phantastical contemners of truth. Happily these two tendencies are in most natural philosophers so well tempered with good sense, that their controversies seldom exhibit any of the exaggerations which have disgraced so many theological and metaphysical controversies; but they always exercise their influence, which is generally a salutary one, in forming an opposition of sentiment in the republic of letters by which stagnation is prevented. This conflict of opinions keeps science alive, and promotes it by an oscillatory progress, though it seems to the common eye a mere fluctuation, without any definite purpose.

The reasons for and against an essential resemblance between magnetism and electricity might, before the discovery of electromagnetism seem to be nearly balanced. The most striking analogies were, that each of them consists of two powers, or directions of powers, of an opposite nature, submitted to the same laws of attraction and repulsion; that the magnetical action on bodies, fit to receive it, has much analogy with the electrical action; that the distribution of the powers in a body, which has an electrical charge, and still more a series of bodies charged by cascade, differs very little from the distribution of the powers in a magnet; if we imagine a Voltaic pile, and principally the modification denominated after Zamboni, composed of minute and molecular elements, it would have the most perfect analogy with a magnet; and lastly, that the tourmaline differs but little from such an electrical magnet.

We shall not here consider that most of these analogies are overturned by the discovery of electromagnetism; but still confining ourselves to the period before this discovery, it may be objected that the magnetical and electrical powers do not act on each other, which should be the case, if they were of the same nature; that all bodies transmit with ease the magnetical action, but not the electrical; that neither the tourmaline nor any system of charged glass-plates, or of galvanical arrangements, has the effects of the magnet. Although it might be answered that the galvanical circuit, in its first period, seemed no less different from any electrical apparatus than the Voltaic pile from a magnet, these objections did not cease to have considerable weight, but we have hitherto deliberately omitted one of the arguments, viz. the observation of magnetism in bodies struck by lightning, and the experiments made to imitate this effect. It had often been observed, that the magnetical needles in a ship struck by lightning have suffered a change in their polarity.

A very remarkable case of this kind, mentioned in the Philosophical Transactions, Vol. xi. No. 127, p. 647, seems to be the earliest on record. It is there related that a vessel, whose mast was struck by lightning, had the poles of the needles in all its compasses inverted, yet the compasses themselves were not struck. Some other observations of a similar nature are recorded in Domsdorph's *Treatise upon Electricity, Magnetism, Fire, and Ether*, (uber Electricitat, Magnetismus, Feuer und Ether, 1783.) An accident of this kind, which happened in the year 1751, caused Franklin to try the effect of artificial electricity upon needles of steel. The result was, that when the needles were in a position in which the earth could produce in them some magnetism, this effect was much increased by any electrical stroke; but when the position gave no such advantage, he found that the extremity of the needle, in which the electricity entered (which received the positive electricity) was directed towards the north, when the needle was conveniently suspended. *Wilcke*, who repeated these experiments, obtained the same results, only with the difference, that in the case when the direction of the electrical stroke seemed to decide the polarity, this was the inverse of that observed by Franklin. (Transactions of the Royal Academy at Stockholm, 1766.) The experiments made in the year 1785, upon the same subject by *van Marum* and van Swinden have been considered as decisive against the magnetical effects of electricity, nevertheless the ninth of their experiments was precisely an electromagnetical one, for they led the electrical discharge transversely through a steel needle, and obtained a strong magnetical polarity in a direction perpendicular to the magnetical meridian; but they considered this as a singularity not to be explained, and hence it has been out of the sight of philosophers from the year 1785 until 1820, when electromagnetism was discovered. (See *Van Marum, description d'une très grande machine électrique.*)

One of the earlier experiments, which probably belongs to electromagnetism, is that of *Cavallo*, by which he proved that iron has more efficacy on the magnetical needle, when an acid, particularly diluted sulphuric acid, acts upon it.

Joh. Will. Ritter, already mentioned, pursued a great number of researches upon the analogy of magnetism and electricity. He had in the year 1801 made a series of very delicate experiments upon the galvanical difference between the two magnetical poles of a steel needle. The result deduced from his experiments was, that the southern extremity of the needle was more oxidable than the northern, and that the galvanical effect of two magnetical needles upon a frog was such, that the south pole acted as the more oxidable, the north pole as the less oxidable metal. It is now acknowledged, that he has been led into error by the difference which a small disparity in the polish of the metal can produce, and which he employed insufficient means to avoid. The same philosopher stated likewise erroneously, that a platina wire, which has been employed to make a liquid communicate with a powerful galvanic circuit, assumes some magnetical direction, and that a needle, of which one half is zinc and the other silver, takes, when conveniently suspended, the same direction as the magnetical needle. The precipitation with which Ritter published these and some other erroneous statements, has thrown a shade over the name of this unhappy but ingenious philosopher, who has enriched science with several discoveries of great importance, and whose profound yet obscure ideas in many cases have anticipated the discoveries of future times. We are far from patronizing a vain exhibition of new ideas, by which it is possible for a very ordinary mind to make pretensions to every new discovery; but when works are marked with the true stamp of genius, it is but justice to acknowledge the merits of their speculations. Some writers have thought that this act of justice would deprive experimental philosophers of a part of the honour due to their exertions; but this honour is quite unimpaired, if the author, who has anticipated their discoveries, has only had a vague and obscure notion of them; while it must be avowed, that when the author has clearly announced the discovery, has derived it from good data and conceived its connections with other truths, the merit of the experimental philosopher is only that of having confirmed it by experiment, which still in many cases can be a work of no smaller claim to glory than the primitive conception itself.

Among the electromagnetical experiments which preceded the discovery of electromagnetism, ought to be mentioned an experiment of Professor Mojon at Genoa, who found that a steel needle having been 22 days in communication with a galvanical apparatus of 100 elements, had become magnetical,—an experiment which would have been of no historical interest, if its author had not founded upon it, 18 years later, a pretension to the discovery of electromagnetism. He seems not to have been aware that his pretended discovery, were it true, should be considered as new even now; for the magnetical effect, hitherto proved by experiments, is not in the direction of the electrical current, but perpendicular to it. The experiment of Mojon is described in *Aldini's Essai Théorique et Expérimental sur le Galvanisme.* Paris, 1804, tom. i. pag. 339 and 340. *Aldini* mentions, at the same place, that a certain Mr. *Romanesi* at Trent had confirmed the experiment of *Mojon*, and at the same time observed that galvanism makes the magnetical needle deviate. Professor *Aldini*, whose work upon galvanism comprehends two volumes, does not say a word more upon this subject.

It is, therefore, not surprising, that neither the French institute, nor the other learned societies, nor the numerous natural philosophers, to which the work was presented in the year 1804, took any notice of this observation, which would have accelerated the discovery of electromagnetism by sixteen years. *Romanesi* seems likewise to have forgot his observation, until electromagnetism was discovered.

Two or three years before the discovery of electromagnetism, Professor Maschmann at Christiania, in Norway, observed that the silver tree, formed in a solution of nitrate of silver, when put in contact with mercury, (the *arbor Dianæ*,) takes a direction towards the north; and the celebrated Professor *Hansteen* found that this direction can likewise be determined by a great magnet. As the metallic precipitation is also of galvanical nature, this observation may be considered as one of the precursors of electromagnetism.

Electromagnetism itself was discovered in the year 1820, by Professor *Hans Christian Oersted*, of the university of Copenhagen. Throughout his literary career, he adhered to the opinion, that the magnetical effects are produced by the same powers as the electrical. He was not so much led to this, by the reasons commonly alleged for this opinion, as by the philosophical principle, that all phenomena are produced by the same original power. In a treatise upon the chemical law of nature, published in Germany in 1812, under the title *Ansichten der chemischen Naturgesetze*, and translated into French, under the title of *Recherches sur l'identite des forces èlectriques et chymiques*, 1813, he endeavoured to establish a general chemical theory, in harmony with this principle. In this work, he proved that not only chemical affinities, but also heat and light are produced by the same two powers, which probably might be only two different forms of one primordial power. He stated also, that the magnetical effects were produced by the same powers; but he was well aware, that nothing in the whole work was less satisfactory, than the reasons he alleged for this. His researches upon this subject were still fruitless, until the year 1820. In the winter of 1819–20, he delivered a course of lectures upon electricity, galvanism, and magnetism, before an audience that had been previously acquainted with the principles of natural philosophy. In composing the lecture, in which he was to treat of the analogy between magnetism and electricity, he conjectured, that if it were possible to produce any magnetical effect by electricity, this could not be in the direction of the current, since this had been so often tried in vain, but that it must be produced by a lateral action. This was strictly connected with his other ideas; for he did not consider the transmission of electricity through a conductor as an uniform stream, but as a succession of interruptions and re-establishments of equilibrium, in such a manner that the electrical powers in the current were not in quiet equilibrium, but in a state of continual conflict. As the luminous and heating effect of the electrical current goes out in all directions from a conductor, which transmits a great quantity of electricity; so he thought it possible that the magnetical effect could likewise eradiate. The observations above recorded, of magnetical effects produced by lightning, in steel-needles not immediately struck, confirmed him in his opinion. He was nevertheless far from expecting a great magnetical effect of the galvanical pile; and still he supposed that a power, sufficient to make the conducting wire glowing, might be required. The plan of the first experiment was, to make the current of a little galvanic trough apparatus, commonly used in his lectures, pass through a very thin platina wire, which was placed over a compass covered with glass. The preparations for the experiments were made, but some accident having hindered him from trying it before the lecture, he intended to defer it to another opportunity; yet during the lecture, the probability of its success appeared stronger, so that he made the first experiment in the presence of the audience. The magnetical needle, though included in a box, was disturbed; but as the effect was very feeble, and must, before its law was discovered, seem very irregular, the experiment made no strong impression on the audience. It may appear strange, that the discoverer made no further experiments upon the subject during three months; he himself finds it difficult enough to conceive it; but the extreme feebleness and seeming confusion of the phenomena in the first experiment, the remembrance of the numerous errors committed upon this subject by earlier philosophers, and particularly by his friend *Ritter*, the claim such a matter has to be treated with earnest attention, may have determined him to delay his researches to a more convenient time. In the month of July 1820, he again resumed the experiment, making use of a much more considerable galvanical apparatus. The success was now evident, yet the effects were still feeble in the first repetitions of the experiment, because he employed only very thin wires, supposing that the magnetical effect would not take place, when heat and light were not produced by the galvanical current; but he soon found that conductors of a greater diameter give much more effect; and he then discovered, by continued experiments during a few days, the fundamental law of electromagnetism, viz. *that the magnetical effect of the electrical current has a circular motion round it.*

When he had discovered this fundamental law, he thought it proper to publish the discovery, in order that it might be as soon as possible perfected by the co-operation of other philosophers. Apprehending that others might lay claim to this discovery, he sent a short Latin description of his experiments to the most distinguished philosophers and learned bodies; and though, by this means, he has not avoided the pretensions which have been made to his discovery by others, still he has rendered them ineffectual. It deserves, perhaps, to be noticed, that the above-mentioned Latin description, consisting of four pages in 4to., of which the first gives the introduction and the description of the apparatus, the last the conclusions, contains upon the two intermediate pages, the results of more than 60 distinct experiments. From this brevity, it has happened, that some philosophers have thought that he had treated his subject in a superficial manner.

As the details of this discovery, and of all those which have originated from it, will be exhibited in this article, we shall in the remainder of this historical sketch, in order to avoid repetitions, confine ourselves to the most striking and leading facts, and insert the other historical notices in the doctrinal part.

The first discovery to which that of Professor Oersted gave occasion, was that of *Mr. Ampere*, member of the French institute. He found that a conductor, conveniently suspended, is attracted by another, when both are transmitting an electrical current in the same direction; but that they repel each other, when the two currents have opposite directions. Professor *Schweigger* at Halle, invented at the same time, an electromagnetical multiplicator, which is of very extensive use. *Mr. Arago* found that steel can be magnetized by the electrical current. *Mr. Gay Lussac* at Paris, and Professor *Ermann* at Berlin, discovered, that when the current has passed perpendicularly through the plane of a steel ring, or through a steel plate, it shows no magnetical effect, before the circumference was interrupted.

The most remarkable of all the discoveries, to which that of *Oersted* has given occasion, is no doubt the thermo-electricity, discovered in 1822 by *Dr. Seebeck*, member of the Royal Academy at Berlin.

In the same year, the rotation of a magnetical needle around an electrical current, and of a body, which transmits an electrical current around a magnet, first imagined by *Dr. Wollaston*, was exhibited in a series of ingenious experiments by *Mr. Faraday*.

Effect of the Electrical Current upon the Magnetic Needle.

The galvanic battery was the first apparatus, by which the magnetic effects of electricity were demonstrated. In order to make it give its magnetic action, its two poles must be joined by a conductor, commonly a metallic wire, which, for brevity's sake, we shall call the *uniting conductor*, or the *uniting wire*.

When not closed, the galvanic circle produces no effect upon the needle of a compass.

When the uniting wire is approached, and placed parallel, or nearly so, to a properly suspended magnetical needle, it is caused to deviate from its ordinary direction.

The magnetical effect of the electrical current is not interrupted by the interposition of other bodies. Already the first experiment showed that it passes like the magnetism of a loadstone through metals, glass, resin, wood, stoneware, water, &c.; even when the magnetical needle was placed in water, it was affected by the electrical current.

When the conducting wire is placed parallel to a conveniently suspended magnetical needle, the direction of the needle is changed.

1. If the needle is above the wire, and the positive electricity passes from the right to the left hand of the observer, the north end of the needle will go from the observer.

2. When the needle is below the wire, the direction of the needle is changed in the opposite way; its north end approaches to the observer. It is not necessary, in this and the preceding experiment, that the needle is in the same perpendicular plane as the conducting wire; it is only required that the needle shall be sufficiently near the wire, and in the first experiment, in a plane above, in the last in a plane below it.

3. When the needle is in the same horizontal plane as the wire, and is placed between the observer and the wire, the north end is elevated.

4. If the needle is upon the opposite side, the north end is forced down. In these two experiments, the needle must be very near to the wire.

From these facts, Professor *Oersted* concludes, *that the magnetical action of the electrical current describes circles round the conductor.* It will perhaps not be out of place to quote here his own words, which have been overlooked by several authors, who have written the history of this discovery.

In the original publication he says, "ex observatis colligere licet, hunc conflictum (the electrical current,) gyros peragere; nam hoc esse videtur conditio, sine qua fieri nequit, ut eadem pars fili conjungentis (conducting wire,) quæ infra polum magneticum posita cum orientem versus ferat, supra posita eandem occidentum versus agat." For the sake of brevity we shall, in the following pages, denominate the direction of the current after the system of Franklin; or, to speak according to the system of two electricities, after the direction of the positive electricity in the current. If we now suppose that the electricity of the current enters the conductor at the right hand of the observer, the austral magnetism (the same which predominates in the north-end of the needle,) will, upon the superior surface of the conductor go off from the observer; on the side most distant from the observer, the austral magnetism goes downward; on the inferior surface it goes towards the observer; on the side nearest the observer it goes upwards. This is represented in Plate DXXII. Fig. 1. where B A is the conductor in which the direction of the current is A B, the circle *c d e f* represents a plane perpendicular to the conductor, in which the magnetical circulation takes place. This plane is here and in the other figures represented as if it were material and opaque. The little arrows show the direction of the austral magnetism. We can make the application of this law to experiments, in a very commodious manner. For this purpose take a piece of paper (Fig. 2,) upon which the arrows and letters, there represented, are drawn. This piece of paper is to be wrapt around a cylindrical body, for instance a pencil, in such a way that the arrows lie in a plane perpendicular to the axis of the cylinder. We have thus an electromagnetical index, which, put in the place of any part of the conductor, shows the direction of the magnetical powers in it. The sharp ends of the arrows indicate the direction in which the austral magnetism (and consequently the north-end of the needle,) is repelled, and the contrary attracted; the opposite ends of the arrows indicate also the direction in which the boreal magnetism (and consequently the south end of the needle) is repelled, and the contrary attracted. The reader may understand without trouble the most complex facts we are here to explain, if he has at hand two such cylinders, during the experiment. The same thing may be expressed in different ways. Mr. Hill, lecturer of mathematics at the University of Lund, in Sweden, has proposed one of the best. Let us imagine, says he, that the observer swims upon the electrical current, with his face turned outwards, (with his back turned towards the axis of the current,) and his head towards the origin of the current, the direction of the austral magnetism of the current will always proceed from his left to his right hand.

This law was confirmed by several other experiments.

When the uniting wire is placed in the same horizontal plane as the needle, but perpendicular to its direction, and near one of its poles, this pole will be elevated, if the current comes from the east, but depressed if it comes from the west. This will easily be understood by the inspection of Plate DXXII. Fig. 3. B A represents here the conductor, N S and N′ S′ two needles. All the parts of the drawing have the same signification as in Fig. 1, only that the dotted lines denote the inferior parts of the magnetical circles, but the uninterrupted lines the superior parts. It is evident that N (the north end of one of the needles) is here driven upwards by the repelling action from below and the attracting one above it. In the same manner, S′ (the south end of the other needle) is both drawn and pushed upwards.

The effect is on both sides the same, because not only the magnetical poles, but likewise the opposite sides have contrary effects. If one of the needles were turned by means of a magnet, so that each side of the wire could act upon a pole of the same kind, one of them would be elevated, when the other was depressed.

When the uniting wire is perpendicular, and the current enters its superior part, a needle, of which one of the poles is very near to the wire, will be thrown westwards; but if the wire is placed over against a point of the needle, situated between one of the poles and the middle, the needle will be turned eastwards. By opposite currents the results are likewise opposite. Fig. 4 will make this easier understood. A B is the uniting wire, the notations the same as in the former figures. It is evident, by the inspection of the figure, that the north end of the needle *a*, having predominant austral magnetism, must be repelled by the similar magnetism of the conductor; and be turned towards the west. The attraction of the opposite magetism in the conductor tends to give the needle the same direction; but as this coincidence of motions, produced by opposite powers, is constant in electromagnetism, we shall always confine ourselves to mention but one of them. The south end of *e*, having predominant boreal magnetism, is also repelled by the similar magnetism of the current, which here has the same direction as the austral on the opposite side of the conductor. Thus the north end of the needle is on one side of the conductor turned the same way as the south end on the other side. The north end of *c* receives the strongest impulses from the west, and must, therefore, be pushed eastward; while the south end of *d* receives the strongest impulses from the east, and must move towards the west, and in consequence of this its north end must also turn eastward like that of *c*. Were the wire placed exactly over against the middle of the needle, this would be solicited equally in opposite directions, and therefore rest at its place.

When the uniting wire is bent in such a manner, that the parts on each side of the flexture are parallel, the exterior surfaces of the two branches are similar, and also the interior ones. In Fig. 5, A C D B represents such a wire. As the current enters the superior branch at C, and in the inferior at B, it is obvious that the directions of the powers in the magnetical circles are the same at *e* and *f*, at *g* and *h*. Suppose that the two branches are in one perpendicular plane, and the north end of the needle is placed in a plane, below the superior and above the inferior branch, the north end will be repelled, when placed on the west side, and attracted, when placed on the north side of the wire. Above the superior branch, or below the inferior branch the effects are in the opposite direction. All the other cases, belonging to the effects of bent connecting wires upon magnetical needles, may be easily explained in a similar manner.

These are the principal experiments, by which Professor Oersted endeavoured to establish the fundamental law of electromagnetism. As they all belong to one class, it has been practicable for us here to maintain in our account the historical order, without impairing the systematical one. In order to have a short term, we shall call the magnetical action of the electrical current, the *revolving magnetism.*

The discoverer remarks, in his Latin publication, that the magnetical action of the current being necessarily propagated and not instantaneous, the association of a progressive and revolving motion must give origin to a spiral motion; still, he adds, this seems not to be required for the explanation of the electromagnetical facts hitherto discovered. His words are, "Præterea motus per gyros cum motu progressivo, juxta longitudinem conductoris conjunctus, cochleam vel lineam spiralem formare videtur, quod tamen, nisi fallor, ad phænomena hucusque observata explicanda nihil confert." Several writers upon the continent have considered it as an essential point in Oersted's theory, that the magnetical motions in the current should be of a spiral form; but it is evident that he has well distinguished this theoretical but still necessary consequence from the fundamental law, deduced from the facts. Supposing here spirals in the place of parallel circles, their windings must be so near to parallelism, that the deviations from it must be imperceptible. Thus the question belonging to the spirals may be left for farther research, in which, perhaps, the whole doctrine of vibrations might be considered.

In an appendix published two months later, (in Schweigger's Journal,) Professor Oersted explained the apparent difference observed between the effect of the galvanical battery, and that of a simple galvanical circuit. In the battery, which is a compound galvanical circuit, as well as in the simple one, the electrical current goes from the more oxidable metal (zinc), through the liquid conductor, to the less oxidable (copper): and when the water is taken away in one of the elements of the battery, and a wire put in its place, the direction of the current remains of course the same; but when we make use of a simple circuit, the water remains at its place, and the uniting wire connects the two pieces of metal in a place, where the direction of the current is the opposite to that of the water. Fig. 6 will make this more perspicuous; Z represents here the zinc, C the copper, W the water, U the uniting wire; the arrows marked with $+ e$ and $- e$ indicate the direction of the electrical current. It is visible that when in W the current goes from zinc through the water to the copper, it must in U go from the copper to the zinc.

In this appendix it is remarked that the magnetical efficacy of the electrical current depends not on its intensity, but on its quantity of electricity, and that the simple galvanical circuit is preferable for electromagnetical experiments. Some time after the discovery of electromagnetism, the great Swedish chemical philosopher *Berzelius* was of opinion that all the effects of the uniting wire could be explained in assuming four magnetical poles in its circumference. Plate DXXII. Fig. 7, where A indicates the austral, B the boreal poles, represents such a distribution. As the appearances in the first electromagnetical experiments may, until a certain degree, be represented by this scheme, it had many adherents, even since Berzelius had abandoned it. In order to decide the question upon this subject, Professor Oersted made a direct experiment which will be understood by Fig. 8. AB is a wooden pillar more than twelve feet high; C is a magnetical needle, protected with glass against motions in the air; DE a wire of brass; K a galvanical apparatus; HGF and OJL brass wire; M and N small cups with mercury. The whole movable part of this arrangement was supported by a wooden frame, not here represented. It appears that the apparatus K with its conductors, whose extremities are plunged in the mercury, can turn around nearly through the whole circle, without an interruption of the continuity of the conductors; thus the same point of the perpendicular wire, though immovable itself, changes every moment its relative place in the circuit, when the movable part FGIL is turned round. The experiment shows that the deviation remains the same, whatever the position of the movable part may be, and that of consequence the polarity must be the same in all points of the circumference of the conductor. The great distance of the other parts of the circuit is the reason that DE is the only one which can have a sensible effect upon the direction of the needle.

A most useful application of electromagnetism is the *electromagnetic multiplier*, invented by Professor Schweigger at Halle, and improved by several other philosophers. We have already seen that when the uniting wire is bent so as to form two parallel branches, each of them acts in the same direction upon one of the poles of a magnetical needle placed between them (Fig. 5.). On proceeding upon this principle it is clearly shown that when the uniting wire is bent several times, as ABCDE, Fig. 9, and a magnetic needle is suspended in the space, inclosed by the windings of the wire, each of its horizontal parts must produce upon the needle an equal effect; thus in the figure the effect is quadrupled. It is to be remarked, that the windings should be as near each other as possible, in order to keep them all very near to the needle. At the same time the windings must be isolated from each other, which is effected by covering the wire with silk. As the windings can be repeated a great number of times, the multiplication of the effect may go very far. It should be nearly without limits, were it not that the conducting power decreases when the length of the wire increases. In order to give the instrument the solidity necessary, the wire is wound upon a frame. As it is required that the needle should be as movable as possible, it is suspended by a fibre of silk, such as is found in the cod of the silk-worm. The instrument may be made much more sensible by means of another magnet placed so as to diminish the directive power of the needle. Mr. Nobili has made a new improvement in this apparatus. In the place of one needle he introduces a compound index, consisting of two needles, NS and S′N′, Fig. 10, in opposite directions, and joined by a piece of wood or of stout wire, GH. When these two needles are of equal strength, the directive power of the index is reduced to nothing; so that the most feeble impulse will move it. But even when one of them has some preponderance, the force required for making the index deviate is still inconsiderable. At the same time this arrangement has the advantage, that both needles receive an impulsion, the needle NS from the inferior side of the conductor, and S′N′ from the superior. The needles being in opposite situations, one will receive the same direction by the superior, as the other by the inferior side of the wire. When the needles approach as much to equality as is required for some nice experiments, the index is too easily moved in some others. In order to make the instrument proper for experiments with various degrees of force, though all of the feebler kind, Professor Oersted added a bent magnet, IKL, which can be placed so as to repel the nearest end of the index, or so as to attract it. The first of these positions is represented in Plate CXXII. Fig. 10. The magnet can also be approached to the index or removed from it. Fig. 11 represents the whole instrument of half its dimensions. AB is a stand of wood, having a screw on each corner for levelling it. CCC, CCC are two supporters likewise of wood, bearing the frame *defg*, upon which the multiplying wire is wound. This wire may be conveniently 50 to 60 feet long, and make 100 or more windings. From the windings each end of the wire passes through a little ring h, (the other is not to be seen in the figure,) at ii the ends of the wire passes also through rings, which are here covered by the other parts of the figure; KK, KKK, are two small pillars of ivory or wood, supporting the transverse piece ll, through which passes the cylindrical piece mp, having a head at m, and being movable upwards and downwards. At the centre r of the inferior extremity, p is a little hole, communicating with a transverse hole, which here is represented as shut with a pin, seen immediately under the ring o. Through the hole at r is introduced one end of the silk rx, which is drawn out through one of the openings of the transverse hole, and fastened by means of the pin abovementioned. By the silk rx is suspended the index, consisting of the superior magnetic needle ns, and the inferior one, of which the extremity n is here visible, the other being covered by other parts of the figure. The boreal pole of one of these needles is turned in the same way as the austral of the other, and both connected with a piece of wire. The circle at whose divisions the index points, is made of glass, preferable to brass, which often is magnetic. At q is a slit to receive the needle and keep it; when the instrument shall be transported, a similar one is on the other side of the instrument. The index is cleared from the slits when the instrument is to be employed. Having been thus cleared, it is still at rest until the piece mp is drawn upwards, the ring o stops it, so that it shall not be elevated too much. The index is sheltered from the air by means of a case of glass which covers the whole frame including the index, and has in the upper part a hole through which the head m of the piece mp passes; tt is a pile movable in the slit yy, which has a scale, showing the distance from a point in the same plane, perpendicular below the centre of the index; uv is a bent magnet, which has two points, one of which is visible at w, the other is placed in a hole in the pile tt. This magnet can be taken out, and the point w introduced in the pillar, in order to augment or diminish the directive power of the index, as the purpose may require. When this instrument is to be used, the index must, as already mentioned, be taken out of the slits, and the piece mp be elevated, so that the index can move freely.

When it is made to oscillate too much it may be brought to rest by lowering the piece mp a moment. If the two needles of the index have exactly the same power, it will have the highest mobility; but if this is not obtained, the bent magnet uv is to be so placed upon the pillar tt that the two nearest poles of the index are repelled. By approaching or retiring the pillar, the magnet may be brought into such a position that the directive power of the index is scarcely sensible. When the instrument is in this state it can make sensible the difference between two pieces of metal, of which one differs only from the other by $\frac{1}{100}$ alloys, when a powerful liquid is applied. When a more considerable effect is to be tried, the bent magnet is put in such a position that it attracts the nearest poles of the index. When the magnet is near the index, and the current makes the index deviate very little, the deviation increases as the magnet is removed. The distance of the magnet being measured by the scale, this arrangement may contribute much to the determination of the powers. As the needles submitted to the effect of the current can never rest at an angle greater than 90°, the needle is prevented from going farther by means of two small pins here marked with the Greek letter φ.

The use of the electromagnetical multiplier is very extensive. Before the invention of this instrument, a prepared frog was considered as the nicest test for galvanism; the multiplier surpasses it by far. Mr. *Poggendorff* has made a very extensive trial upon the galvanic series of metals and other conductors, by means of this instrument. Professor Oersted has made use of it, for confirming the discovery earlier made by *Zamboni*, upon electrical currents which two pieces of one metal makes with a liquid. He has also discovered, by means of this instrument, that two equal pieces of metal give galvanical effects, when one of the pieces is earlier introduced in the fluid than the other, a fact which Sir Humphry Davy has confirmed, as it appears, without knowing Oersted's experiments. Professor Oersted has also made use of this instrument for trying silver. With a powerful liquid conductor, solution of potash and muriatic acid for instance, silver pieces, whose alloy differs less than a hundredth, give a deviation of several degrees. As silver containing brass gives more effect than silver containing an equal quantity of copper, when muriatic acid is employed, but less when solution of potash is the liquid conductor, the presence of brass in silver is easily discovered by this instrument. It need scarcely be mentioned that gold and other metals may be tried in the same manner. Dr. Seebeck, at Berlin, has investigated, with much care, all the circumstances belonging to the construction of the multiplier. These researches are given in an excellent paper, read at the Royal Academy of Berlin, on the 14th December 1820, and the 8th February 1821, containing a valuable detail of experiments upon several points of electromagnetism. Dr. Seebeck has proved, by experiment, what might be presumed in theory, that the increase of the effects of the multiplier, with the number of the turns, is limited by the resistance against the transmission increasing with the length. The effects of the multiplier increase also with the breadth of the conductor, which he made of a long and thin lamina, in the place of a wire; still the advantage of broad conductors is only confined to experiments with considerable powers: in feeble currents the effects of broad and narrow conductors are equal.

Several philosophers have given themselves much trouble to produce upon the needle, by means of common electricity, the same effects as those produced by galvanism. A simple electric spark transmitted through a conductor passes too speedily to move the needle. A current produced by the electrical machine does not seem to contain a sufficient quantity of electricity for acting upon the needle without the aid of the multiplier. Even by this instrument it was tried often, without decided success, until of late Mr. Colladon, at Geneva, repeated the experiment with a multiplier, in which the wire was covered with three folds of silk, and thus well isolated. When he approached the two ends of the wire of this instrument to the two conductors of an electric battery of 4000 square inches, so as to make the discharge go a little distance through the air, before it enters in the wire. In this manner a current sufficiently strong, and of some duration, is produced, whereby a considerable deviation is effected. The current produced by an electric machine caused also a deviation of several degrees in this instrument.

Professor Oersted proposed, in a paper printed in Schweigger's Chemical Journal, 1821, to make use of magnetical needles, suspended in various directions for investigating the electrical currents in the atmosphere; but he has published nothing since that time. Mr. Colladon has, with full success, employed the multiplier, to prove the presence of electromagnetism in a thunder storm.

The idea of magnetical revolutions around the uniting wire experienced much opposition at its first publication. Professor Schweigger objected to it, that when such revolutions did exist, it would be possible to make a magnet circulate round the uniting wire. Dr. Wollaston drew the same conclusion, but with the contrary meaning; finding this result probable, he invented an instrument to prove it. The experiment having been stopped by an accident, Mr. Faraday took it up, and made an extensive series of experiments on the subject, conducted with the same skill which he has displayed in so many other investigations. He found that not only the magnet may be made to turn round the conductor, but that likewise a movable conductor, may be made to turn round the magnet. We shall have an opportunity to return to this subject; here we can only give an account of the experiments by which the motion was communicated to the magnet. Plate DXXII. Fig. 12, represents an apparatus proper for the experiment; CCCC represents a cup of glass, or some other non-conductor, through the bottom of which passes the conductor EFG. The cup is filled with mercury, in which a small magnet AB floats, being kept in a vertical position by a piece of platinum, fixed at its inferior extremity. It can also be kept in this position by fixing the inferior extremity to the bottom by means of a short thread of silk. *D* is a conductor whose lower end dips in the mercury. When a strong electrical current is now caused to pass through this arrangement, the magnet revolves about the conductor D. The directions of the rotations are in all cases such as the fundamental law of electromagnetism indicates that they should be. A magnet can also be made to turn round its own axis by an electrical current. Let CCCC, Fig. 13, be a cup of glass or wood, nearly filled with mercury; AB a magnet, having at its lower extremity a steel point, introduced into the agate H. JK is a slip of brass or ivory, having a hole through which the magnet passes freely, and by means of which it is kept perpendicular at the superior extremity; A, is a cavity for receiving mercury; EF is a wire, at whose extremity is also a cup for mercury; and at D is placed a similar one, from which proceeds a wire amalgamated on its lower extremity, in order to favour the electrical communication. When the electrical current is established by conductors plunged in the mercury at D and F, the magnet will turn with great rapidity.

On the power of the Electrical Current in developing Magnetism in other Bodies.

In a paper read before the French Institute, the 25th September 1820, Mr. Arago showed that the electrical current possesses, in a very high degree, the power of developing magnetism in iron and steel. Sir Humphry Davy stated the same facts in a letter to Dr. Wollaston on the 12th November 1820. Dr. Seebeck communicated to the Royal Academy at Berlin, the 14th December, an excellent series of experiments upon the same subject. Thus treated in the space of three months by three so highly distinguished philosophers, the subject was nearly exhausted in the same year that the discovery was made. The uniting wire of a powerful galvanic apparatus attracts iron-filings often with such a power as to form a coating around the wire ten or twelve times bigger than itself. Mr. Arago found that this attraction did not take its origin from any previous magnetism in the iron-filings, which could touch iron without adhering to it; nor was the attraction to be considered as a common electrical one, since brass and copper filings were not attracted. He found also that the iron-filings began to move before they came in contact with the uniting wire. Hence it must be admitted that this attraction is operated by converting each little piece of iron into a temporary magnet. Greater pieces of soft iron were also converted into temporary magnets, and small steel-needles into permanent magnets. Sir Humphry Davy had, in his researches, obtained the same results, before he had got notice of the experiments of the French philosopher. Dr. Seebeck seems to have been in the same case, when he made his experiments; but he had received notice of Arago's experiments when he published his own. The direction of the magnetism produced is always according to the fundamental law. Let the circle in Fig. 14 represent a horizontal section of a perpendicular conductor, in which the current comes from above; let the little arrows indicate the direction of the revolving magnetism, and BA, BA, BA, BA, some steel needles; then these needles will obtain austral magnetism at A, and boreal magnetism at B.

Dr. Seebeck found that a steel needle was strongly magnetized when it was drawn around the conductor. The direction of the magnetism was the same as it should be, if the needle had been laid closely around the conductor, and afterwards removed. He laid also an armour of soft iron on both sides of the conductor, which hereby was made able to bear a considerable weight of iron.

Mr. Arago and Mr. Ampère, employed in the development of magnetism the principle of the multiplier, without having notice of the discovery of Schweigger. A steel needle AB covered with paper, was surrounded by a winding of the uniting wire EE, as represented in Plate CXXII. Fig. 15. The steel-needle may also be included in a glass tube. The great galvanic apparatus of the London Institution is now found to develope magnetism in such an eminently high degree, that a little steel bar, by falling through a glass tube, around which the windings of the uniting wire passed, was magnetized to saturation.

The electricity produced by friction, when employed in sufficient quantity, developes likewise magnetism in steel. The discharge of an electric battery, and even of a single bottle, magnetises a steel needle. All these magnetical effects are submitted to the same law as those of the galvano-electrical current, and hence they are also increased upon the principle of the multiplier. When the discharge passes through the air across the steel-needle, the magnetism developed is feebler than it is when the electricity passes across it through a metallic conductor.

Mr. Savary, at Paris, has of late discovered that steel-needles placed at different, yet small distances from a wire, through which passes an electric discharge, do not all obtain magnetism in the same direction. In one of his experiments he caused to pass the discharge of a battery having twenty-two feet surface through a platina-wire of about three feet in length and one-hundredth of an inch in diameter. The needles in contact with the wire became magnetised in the direction commonly observed, which he calls the positive direction, but a needle placed at the distance of 1.1 millimetre, about $\frac{1}{24}$ inch, becomes magnetic in the opposite direction, which he calls the negative. At the distance of 2 millimetres a needle was not made magnetic by the discharge. At the distance of 3 to 8 millimetres the needles become magnetic in the positive direction, but most at the distance of 5.5 millimetres. From 8.6, to 21.4 millimetres, the magnetic direction was negative, with increasing intensity from 8.6, to 14.6, and with decreasing from this point until 21.4, where it was nearly at zero. From 23 millimetres distance the magnetic direction became again positive. As for different conducting wires, he found, that within certain limits the maximum of effect is the more distant from the wire, and the numbers of alternating directions the greater, in the same degree that the wire is shorter in comparison to its length. In a helix of narrow windings, needles placed parallel to its axis obtain all the same kind of magnetism, but by varying the electrical power, from that of one bottle of Leyden, to that of a battery of twenty-two feet surface, he obtained, in one experiment, six alternations, viz. three positive and three negative. When the needles are included in a metal coating, for instance, wrapt in a lamina of tin, the effect is changed. If the coating is thick, the effect is nothing, but by a coat sufficiently thin the effect may be increased. When the conducting wire is straight, a plate interposed between the wire and the needle, if thin, augments the effect, if thick, diminishes it; a certain thickness may also be found by which the plate is without effect. The needle is in all these experiments in contact with the plate. When the plate is not interposed, but the wire placed upon the plate, the effect of a very feeble discharge is increased by the plate, and still more the thicker it is. At a certain degree of discharge a thin plate diminishes the effect, a thick plate augments it. The effect of very considerable discharges is always reduced to nothing, or inverted by thick plates. By the galvanic arrangement the same effect is not produced, when the current is uninterrupted, but analogous effects to those mentioned may be produced by an apparatus which has intensity enough to give sparks at the moment of closing the circuit. The current must, for this purpose, only be established for a moment; a constant current destroys the alternations.

The analogy of these effects, with those alternations, which may be produced in bad conductors by common electric experiments, is obvious.

Mr Hill, at Lund in Sweden, has found that when the discharge passes along a magnetical needle, exactly through its axis, all its magnetism is destroyed. He even considers this as the best means to take away the magnetism of a needle. At the same time he remarks that when the electric charge does not go through the axis, a feeble magnetism is developed on both sides of the line of passage, which probably has led preceding philosophers into an error respecting the magnetical effects of electricity. (Schweigger's Journal for the year 1822, No. 3.)

Professor Ermann at Berlin found that when the electrical discharge passes perpendicularly through the centre of a round plate of steel, it reveals no magnetism, but when a split is afterwards made in the plate, or a sector cut out of it, the opposite side of the gap shows the opposite magnetism. The celebrated Gay Lussac and Mr. Welther, without knowing the experiment of the Prussian philosopher, discovered the same fact in a steel ring. This experiment is very illustrative; it shows that the steel disc or steel ring, whose circumference has been in the same state as that of the uniting conductor, preserves after the cessation of the current a latent magnetism, resembling that of a magnetic circle, composed of small magnets, connected by their opposite poles. Such a circle is ineffectual when the circumference is closed, but becomes a magnet when opened. This magnetism was, however, effectual during the time that the ring or disc was comprehended in the current, wherein its magnetism at every moment received a new impulse. Hence we may conclude that the circumference of the uniting conductor is not to be compared with a magnetic circle, wherein the powers are at rest, which is the theory brought forwards by *Mr. Prechtel*, director of the polytechnic school at Vienna; but our experiment confirms the original idea of the magnetical effect of the current as produced by a revolving magnetism.

This view of the subject, that the magnetism of the electrical current is a magnetism in motion, has been overlooked by a great number of authors who have written upon electromagnetism: while it has been adopted by two highly distinguished philosophers, Dr. Wollaston and Mr. Biot. The difference between magnetism in motion and at rest being until our time unexemplified, this view appeared to many philosophers as a mere postulate, which they tried to avoid, by adopting some other theory, particularly the elaborate theory of Ampere, of which we shall afterwards speak. Now the theory of revolving magnetism has obtained a considerable support by the discovery of Mr. Arago, who, in his researches on the effect of metals upon the oscillations of the magnetic needle, found that it was much affected by a metallic plate, for instance a copperplate, when either the needle or the plate was put in motion. There is certainly but few philosophers who have not repeated Arago's remarkable experiment by which a rotatory plate of copper or some other metal puts a magnetic needle conveniently suspended, into a revolving motion. We must pass in silence the numerous and skilfully conducted experiments of Mr. Barlow and Dr. Seebeck, and only quote for our purpose those of Messrs. Herschel and Babbage, by which it is proved that a rotating magnet causes a conveniently suspended metallic plate to turn round. Mr. Poisson has read before the French Institute an elaborate mathematical treatise upon the theory of moved magnetism. Thus the theory of revolving magnetism has obtained the only confirmation which could still be desired.

Effects of the Magnet upon the Uniting Wire.

Professor Oersted, in the prosecution of his experiments, was well aware that a movable part of the electric circuit must be attracted and repelled by a magnet after the same laws by which the uniting wire acts upon the magnet. He published, two months after his first electromagnetical paper, another paper, in which he gives an account of an experiment he made; he found that a little galvanical circuit, suspended by a thin metallic wire, was put in motion by a magnet. He complains himself in this paper, that he had not succeeded hitherto in getting an apparatus sufficiently movable to be directed by the magnetism of the earth (Schweigger's Journal.) Professor Schweigger at Halle, and professor Erman at Berlin, both invented, without knowing Oersted's experiment, apparatuses fit for the same purpose. It would be tedious to give an account of all the experiments made upon this subject; a short description of those which are considered as the best will be sufficient. Plate DXXII. Fig. 16 represents, with some slight modifications, an apparatus invented by Mr. Ampere. A B C D E F G H is a bent wire, of which the two ascending parts at B and G are isolated from each other by some non-conductor and tied together. At A, and also at H, is soldered a steel point, which reposes on the bottom of a small iron cup filled with mercury, at K and M. J K and L M are brass wires, N O a piece of wood, in which they are inserted, and by means of which they can be fixed at a convenient place. It appears that when the current enters at the end of one of these wires, for instance at J, it is obliged to pass through the whole movable conductor A B C D E F G H, and go out at the other end L. This conductor is put in motion with much promptitude by means of the magnet. In comparing this arrangement with Fig. 5, it is obvious that the part D E F G of the movable conductor, in which the current enters at D, is quite analogous with B D C A, Fig. 5, and that therefore the austral magnetism on the interior side of both is turned toward a spectator placed over against the place represented by the figure. It is also evident that the magnetical direction is the same in the part B C D, which turns the same side to the space included by the movable conductor. Thus a magnet whose austral pole is directed against this space will repel the conductor, but placed near to a point of the exterior side it will attract it. On the opposite side of the plane B C D E F G, all the effects are opposite to those here mentioned.

The magnetism of the earth is likewise able to give a direction to the suspended wire. This direction must, in the northern hemisphere, be the same which is produced by a magnet placed below the wire with its austral pole above, and its magnetical axis put in the direction of the dipping needle; which direction is the same as that which a magnetical needle should tend to give the wire if it were fixed below it, in the same position which the current gives it. Thus the plane C D E F must be directed perpendicularly to the magnetical direction; when the current enters at A, the perpendicular part F E will be placed towards the west, but towards the east, if the current enters at H.

The same reasoning may be employed in all other cases where a movable uniting wire is exposed to the influence of terrestrial magnetism; for instance, when the wire is suspended in such a way as to permit the particles to move only in vertical planes. Plate DXXII. Fig. 17, represents an arrangement of this kind. A B C D is a wire, whose two extremities are wrapt round the ends of a thin axis of some non-conductor, and are terminated by two steel points, *a* and *d*, destined to be placed in two steel cups filled with mercury, and communicating with a galvanic apparatus. In order to give it the mobility necessary, it is nearly balanced by a counterweight at E. When the axis is placed perpendicularly to the direction of the magnetic needle, and the current enters at *a*, that is in the west, the plane A B C D will be driven out of its perpendicular position, and deviate towards north: but if the current enters at *d*, the deviation will be austral. If the axis A D is placed in the direction of the magnetic needle, the deviation will, in the first case, be towards the west, in the last towards the east. The boreal pole of a magnet, placed below B C produces the same phenomena; the deviation goes always to the left of the current.

The principle of the multiplier has also been applied to the movable uniting wire. Fig. 18 represents one of these contrivances invented by Mr. Ampere, and somewhat modified by Professor Van de Ross. On the extremity A of the wire is a steel point, resting in a cup with mercury: B is a part of the wire, which forms spirals, fixed on a circular piece of pasteboard, through whose centre it passes at the last, and is prolonged to C, which dips in a cup of mercury. Another apparatus, likewise invented by Mr. Ampère, is represented in plate DXXIII. Fig. 1. The wire passes through a glass tube, from A to B, it is then wrapt around it, and being returned to the extremity A, passes also around C D, and being arrived at D is drawn through the tube, and descends finally to the inferior cup.

Another apparatus of Mr. Ampère, improved by Mr. Marsh, destined to show the magnetical effect of the earth upon the uniting wire, is represented Fig. 2; A B is a cup of glass nearly filled with a convenient liquid, containing a galvanical arrangement, and kept swimming upon a liquid by a piece of cork; the uniting wire is like that of Fig. 1.

In the same manner as a magnet can be made to revolve round the uniting wire, so can a movable uniting wire be made to revolve round a magnet. Fig. 3 shows the principal parts of an apparatus for this experiment; C C C C is a glass cup having a hole through its foot, into which is inserted a copper tube, soldered to a copper disc, cemented to the foot of the glass. The wire E F is also soldered to another copper disc upon which the glass rests; *n s* is a magnet inserted in the copper tube. The cup is filled with mercury. At *a* there is a sort of ball and socket joint, by means of which a wire *a b* is put in communication with the arm D H of a brass pillar: both the socket and the ball are amalgamated, and a piece of silk fixed to the ball or head of the wire, passes through a hole drilled in the arm D H, and by which the wire *a b* is suspended, thereby preserving the contact, and leaving to the latter a perfect freedom of motion. When the current is established, the wire *a b* will revolve about the magnet. The directions of the rotations are such as the theory indicates.

We have seen that a magnet can be made to turn round its axis. An apparatus has likewise been contrived for producing the same phenomena in a movable uniting wire. For shortness sake we shall here omit the description of it, while we give the description of a very simple turning apparatus invented by Mr. Ampere, and whereof a perpendicular section is exhibited in Fig. 4. A B C D and *a b c d* are two cylinders of copper, soldered to a bottom of copper, in such a manner that the space between the two cylinders is able to contain a liquid, but the interior cylinder is left open at both its ends. To *a* and *b* is soldered a bent copper wire, having a cavity at F. *z z* is a light cylinder of zinc, to which is also soldered a bent wire, in the middle E of which is a steel point resting in the cavity F, and consequently the cylinder *z z* will move upon its point of suspension. When the space between the two cylinders is filled with a convenient fluid conductor, an electrical current is established. Now, if a magnet N S is introduced into the cylindrical space of *a b c d*, the cylinder *z z* will begin to turn. When the north end (the austral pole) is upwards, the motion is from left to right of the observer, and the contrary with the magnet reversed; all as it could be predicted from the fundamental law of electromagnetism.

Another ingenious contrivance, invented by Mr. Barlow, is represented in Fig. 5, where A B is a rectangular piece of hard wood, C D a wooden pillar, D E F a piece of stout brass or copper wire, *ab* a somewhat smaller bent wire, soldered to it at F, through the legs of which passes the axis of a wheel W, of thin copper, *h f* is a small reservoir for mercury, and *g i* a narrow channel running into it. H is a strong horse shoe magnet. Mercury being now poured into the reservoir *h f* till the tips of the wheel are slightly immersed in it, and the surface covered with weak dilute nitric acid, let the connexion with the battery be made at *i* and *D*, and the wheel will immediately begin to rotate. If the current or the magnet be inverted, the motion of the wheel will also be reversed. In order to understand this experiment, it must be remarked, that each radius of the wheel which touches the mercury, is a part of the uniting conductor, of which one side is repelled by the austral, the other by the boreal pole of the magnet; thus it must either tend to raise or depress each of these radii.

Sir H. Davy has exhibited the rotation of a conductor by means of mercury. When in a shallow non-conducting vessel containing mercury, the conductors of a powerful galvanical arrangement are plunged at some distance from the sides, and one of the poles of a strong magnet is brought from below to the bottom of the vessel, near one of the conductors, the mercury round this conductor will form a vortex about it. The directions of the motions are always according to the poles and conductors in action, such as the fundamental law indicates.

When a movable part of the uniting wire is placed in the direction of the dipping needle, it cannot be put in motion by the magnetism of the earth: but when it is placed in another plane, though under the same inclination, it is put in motion. Professor Pohl at Berlin, has invented an apparatus, represented in Plate DXXIII. Fig. 6, exhibiting this phenomenon. AB is a piece of board, supported by screws, by means of which it can be levelled. *CD* is a wooden pillar, whose superior part is immovable, and has on its top an agate, which serves to support a steel-point, whereupon rests a wire EF, balanced by a counter-weight G. At E is a cavity containing a drop of mercury, by means of which one of the conductors, whereof only a part, H, here is represented, may be made to communicate with the movable wire. JKL is a circular channel containing mercury, which can be put in communication with the galvanic apparatus through a conductor at M. When a powerful electric current is transmitted through the apparatus, EF can only rest in the position of the dipping needle; in all others, it moves until it arrives at that position, which it nevertheless will leave by the motion already obtained. Hence it must still continue to turn, when it is not stopped, to the position in which it is possible for it to rest.

Mutual Action of Electrical Currents.

Mr. Ampère found, soon after the discovery of electro-magnetism, that *two conductors attract each other, when they are transmitting electrical currents of the same direction, but that they repel each other when the currents have opposite directions.*

The movable conductor, represented in Plate DXXII. Fig. 16, and already described, may be employed to prove this by experiment. As the current which passes through the movable wire ABCDEFGH, has in CD the opposite direction of that in FE, the same uniting wire, which attracts one of these, will repel the other. This experiment may be exhibited in various shapes; but it does not appear that any experiment which could not be made by this simple apparatus is necessary for confirming the law above mentioned.

This law may easily be deduced from the fundamental law of electro-magnetism, as may be seen by Plate CXXIII. Fig. 7, which represents two parallel currents of equal direction, and expressed by the same signs of which we have made use in the preceding pages of this article. It is here evident, that the boreal magnetism at *b* meets with the austral at *a*, and that the austral at α meets with the boreal at β, thus the effect must be attraction. In Fig. 8, two currents of opposite directions are represented, where the boreal magnetism at *b* meets with that at β, and the austral magnetism at α with the similar at *a:* which must produce repulsion.

When the currents are not parallel, but form an angle, they attract each other when both are directed either towards the apex or in the contrary way, but they repel each other when one of the two currents is directed towards the apex at the same time that the other goes off from it. Fig. 9. represents two currents which go from the apex. The boreal magnetism being in one of these directed from *a* to *b;* the austral magnetism in the other from β to α, the result must be an attraction by which the conductors, if one of them is movable, are brought to parallelism. The figure represents only one side of the conductors; but the opposite sides, having both their magnetical directions reversed, will likewise be attractive. It is also easily understood, that the opposite magnetical poles are directed against each other, and produce attraction when the current in both conductors goes towards the apex of the angle. Fig. 10. represents two currents having opposite directions with respect to the apex of the angle. Here the similar poles in the magnetical rotations are directed against each other, and therefore produce repulsion, such as to place both conductors in the opposite ends of one straight line, if one of them is movable.

This may be confirmed by means of the apparatus represented in Plate CXXIII. Fig. 11, consisting of two parts, viz. a movable conductor, A C B, and a multiplying wire D E F G. The movable wire is terminated by two steel points at A and B, which are to be placed in two small steel cups filled with mercury, and communicating with a galvanic apparatus. The multiplying wire is preferred to a straight one, in order to increase the effect. The upper part D E, of the multiplying wire is placed at the same height as the branch B C of the movable conductor; but in such a position that both conductors prolonged would form an angle. The extremities F and G of the multiplying wire are to be put in communication with a galvanic apparatus.

Mr. Ampère, to whom we are indebted for the discovery of the mutual attractions and repulsions of the electrical currents, considers the law of this action as a fundamental one, at least so far as our present knowledge extends. He thus admits no rotative action in the electrical current, but he transports it to the magnet, in which he supposes electrical currents, revolving in planes perpendicular or nearly perpendicular to the axis of the magnet. At first he supposed that all the currents had their centres in the axis, and were situated in planes perpendicular to this axis, but as he soon found that this would not represent the phenomena, he supposed that each atom of the magnet was surrounded by electrical currents, still revolving in planes perpendicular to the axis of the magnet. When Mr. Poisson, however, showed, that in consequence of this view the greatest effect of a magnetical bar would be placed in its extremity, contrary to experiment, he changed this supposition, and at present he is of opinion that the currents are situated in a plane somewhat inclined to the axis of the magnet.

By these suppositions, and a considerable exertion of mathematical skill, he is enabled to make this view represent well enough the phenomena, though his theory is very complicated. It is not necessary here to enter into a discussion on all the points of this theory, as simple consideration of the fact upon which it is founded will be sufficient to decide the question.

Let us suppose that electromagnetism had not been discovered before the discovery of the mutual action of electrical currents, the application of the common philosophical rules should enable us to discover therein the rotative character of the action. The fact is, as above mentioned, that parallel currents attract each other when they have the same direction, and repel each other when they have opposite directions. Now it is to be remarked, that two parallel things of the same direction have their opposite sides placed against each other: the left of the one is nearest the right of the other: but two parallel things of contrary directions have their similar sides turned against each other: right against right, or left against left. Thus the fact reduced to the simplest philosophical expression is that *two points of electrical currents repel each other by their similar sides, and attract each other by their opposite sides.* The most direct enunciation of the experimental result cannot here be considered as at the same time the expression of the philosophical one; for it is evident that two parallel things cannot act upon each other immediately, but only by some transverse action, which here shows itself as consisting of attractions and repulsions in opposite directions, or in other terms, as having polarity. But such contrary powers forming a circle, should keep themselves in equilibrium, and produce no effect without their limits, were they not in motion. Thus the very experiment of Mr. Ampère should, in the absence of all other evidence, be sufficient to prove, *that the electric current contains a revolving action, exhibiting every appearance of polarity.* We do not mean to ascertain the nature of these attractions and repulsions; but it has been our object only to point out the more immediate consequences of the facts.

Electromagnetical Currents produced by Heat.

Dr. Seebeck, in his researches upon electromagnetism, extended at the same time his investigations to the laws of galvanic action, and among these to the influence of heat in galvanic arrangements. Some phenomena here occurred to him which led him to think that two metals, forming a circuit, might produce magnetism when the equilibrium of heat in it was disturbed. Experiment confirmed this opinion. Plate DXXIII. Fig. 12. represents such a circuit; let ABC be a piece of bismuth, and ADC a piece of copper, and let one of the junctions, *A* for instance, be heated, an electrical current will be established, which here can only betray its existence by the magnetical needle; this indicates all the magnetical properties of an electrical current, and, in the instance here mentioned, the current goes into the heated junction from the bismuth to the copper. Dr. Seebeck is not inclined to consider the effect thus produced as a true electrical current, but an effect *sui generis:* and indeed we have not hitherto been able to discover in this circuit either any chemical effect, nor heat or light; still we can represent all the phenomena of Dr. Seebeck's circuit by the same terms as those of the common electrical current: and in the explanation of all the facts, it will appear highly probable that this current is truly a particular kind of electrical one. Professor Oersted has proposed to call the current discovered by Dr. Seebeck the *thermo-electrical* current, and in consequence of this to distinguish the action hitherto called Galvanism by the name of the *Hydro-electrical current.* Hence we have now the names *thermo-electricity* and *hydro-electricity,* to which we could add the name *tribo-electricity* for the electricity produced by friction. Dr. Seebeck has made a very considerable number of experiments upon the thermo-electricity produced by the metals and other perfect conductors. In a circuit containing bismuth, together with one of the other metals, he finds that, in the heated junction, the current goes always from the bismuth to the other metal; of course the bismuth loses, at that point, positive electricity. This we shall, for shortness sake, express thus: bismuth becomes negative with all other metals in the thermo-electrical circuit. In the same sense tellurium may be said to become positive with all other metals. It appears already by these two examples, that the thermo-electrical order of the metals is not the same as the hydro-electrical; and indeed the experiments of Dr. Seebeck have proved that these two orders are discrepant throughout.

The order of the metals, beginning with that which becomes negative with all others, is,

1. *Bismuth.*
2. *Nickel.*
3. *Cobalt.*
4. *Palladium.*
5. *Platinum.* Several pieces of this metal gave very different results, even those which came from the same workshop. Three pieces from Jeannetty's platina manufacture were placed in the order of their effects very far from each other. The pieces which kept this place here between palladium and uranium were prepared by Dr. Wollaston, Mr. Bergemann, chemist at Berlin, Mr. Trick, chemist, appointed to the manufacture of china at Berlin, and Mr. Jeannetty at Paris. As one of these pieces was prepared by Dr. Wollaston, and the two Berlin chemists being men of much chemical skill, we may consider this place as that of the pure platinum, if Mr. Becquerel had not found that two parts of the same platinum wire give a considerable thermo-electric action, when one of them was drawn out so as to become much thinner. Hence it appears that the density of the platinum has a considerable influence upon its thermo-electrical effect. This might perhaps also be the case with other metals.
6. Uranium.
7. Copper, reduced from the oxide by means of black flux, Comp. No. 12.
8. Manganum.
9. Titanium.
10. Brass, some specimens. (Comp. No. 13.)
11. Gold, of Hungarian ducat containing $\frac{1}{90}$ alloy of silver and copper.
12. Copper, occurring in the trade, and containing no silver, iron, lead, or sulphur. (Comp. 21.)
13. Brass, some specimens. (Comp. No. 10.)
14. Platinum, a piece of unknown origin. (Comp. No. 5, 18, 29.)
15. Mercury, the purest occurring in trade.
16. Lead, specimens occurring in trade, and pure lead.
17. Tin, English and Bohemian.
18. Platinum, A bar from Jeannetty's manufacture.
19. Chromium.
20. Molybdænum.
21. Copper, occurring in trade, and containing neither silver, iron, lead or sulphur. (Comp. 12.)
22. Rhodium.
23. Iridium.
24. Gold, *a,* purified by antimonium, *b,* reduced from the oxide.

25. Silver, *a*, purified by cupellation, *b*, reduced from the chloride of silver.
26. Zinc, *a*, occurring in trade, *b*, pure zinc.
27. Copper, reduced from sulphate of copper, *a*, by iron, *b*, by zinc. (Comp. 12. and 21.)
28. Wolfram.
29. Platina, some specimens, (Comp. 5, 14, 18.)
30. Cadmium.
31. Steel.
32. Iron, *a*, occurring in trade, *b*, pure iron.
33. Arsenic.
34. Antimony, *a*, occurring in trade, *b*, pure.
35. Tellurium.

In this series, Dr. Seebeck found that though most of the metals placed here near each other give only a feeble effect, and the more distant a stronger effect, this rule is not constant; tellurium, for instance, gives with bismuth less effect than antimony. With most of the metals in the series tellurium produces a feebler effect than antimony; with silver it produces more effect than with most of the metals placed above it. Antimony produces more effect with cadmium than with mercury. Iron produces only a feeble effect with most of the other metals, and particularly with nickel and cobalt. Of such exceptions Dr. Seebeck has found a great many.

Dr. Seebeck also examined the thermo-electrical powers of several other bodies. Sulphuret of lead becomes negative even in contact with bismuth. Some other sulphurets, as sulphuret of iron, of arsenic, of cobalt and arsenic, of copper, all with a maximum of sulphur, stand in the thermo-electrical series very near to the bismuth. On the contrary, the sulphurets with a minimum of sulphur stand very near to antimony; that of copper stands even under antimony.

Dr. Seebeck found also that concentrated nitric and sulphuric acids are to be placed above the bismuth, but that a concentrated solution of potash or of soda, obtains a place below antimony and tellurium.

Dr. Seebeck constructed also circuits of two pieces of one metal; heating or melting one of the pieces, and putting one extremity of the other piece, which must be bent, in durable contact, while the opposite extremity was in temporary contact with the heated piece. A bent silver wire was, for instance, plunged first with one of its extremities and afterwards with the other in melted silver; the magnetic needle indicated that the current was directed from the melted metal to that extremity which had been the longest time in contact. The same effect, though feebler, was observed when the silver had ceased to be liquid. When a platina wire is tried with a heated piece of platina the direction of the current is opposite. The general result of Seebeck's experiments is, that in the metals of the superior part of the thermo-electric series the direction of the current is as in the platina going from the heated metal to that extremity of the bent piece, which is latest put in contact with it; but in the inferior part of this series the current goes, as in the silver, from the heated metal to that extremity of the other metal, which has been longer in contact with it.

As soon as the thermo-electrical current was discovered, it was obvious that a compound thermo-electrical circuit might be formed in analogy with Volta's complex hydro-electrical circuit. This consequence did not escape Dr. Seebeck, but discovering some opposing circumstances, which we shall soon mention, he bestowed little labour upon this subject, to which he perhaps proposed to return another time. Baron Fourier and Professor Oersted undertook, without knowing this observation of Dr. Seebeck's, a similar research. Their first complex thermo-electrical circuit was a hexagon formed of three pieces of bismuth and three of antimony soldered together. One of the sides was put in the magnetic direction, and a compass placed below it, when first one of the junctions was heated, then two, not adjacent junctions, were heated, at last three, still leaving between two heated junctions one which was not heated. The compass needle changed its direction some degrees by the heating of one of the junctions, still more by the heating of two, and most when all the three junctions were heated. By cooling the three junctions by means of ice, and leaving the three others to the temperature of the atmosphere, similar and even more comparable effects were produced. By heating three alternating junctions, and cooling the other with ice, the effect rose to 60° of the compass used in the experiment. In another series of experiments a rectangular circuit of 22 bars of antimony and 22 of bismuth soldered together was employed. Here likewise as in the preceding experiment, the combined effect of heating and cooling was employed. Now the circuit was opened by dissolving one of the junctions, and, in order to establish the circuit, when required, a little cup of brass destined to contain mercury, was soldered to each of the two bars, whose conjunction was interrupted. A copper wire of about 4 inches in length, and $\frac{1}{25}$ inch in diameter re-established nearly the current; and by two parallel pieces of this wire the current was brought to the full effect. A wire of the same diameter, but a little more than three feet long, was found a tolerably good conductor, while a platina wire of $\frac{1}{50}$th inch and about 16 inches long scarcely transmitted a fortieth of the effect. Liquid acids and solutions of alkalies or other metallic oxides, which prove excellent conductors in the hydroelectrical current, were found quite isolating in the thermo-electrical circuit. Two discs of silver, separated only by a lamina of the thinnest blotting paper, moistened with sulphate of copper, isolated likewise the whole effect of the thermo-electrical current.

The thermo-electrical current, even the most intense that was tried, produced no visible chemical effect; nor was it capable of producing heat in thin metallic wires, probably because they are too feeble conductors of thermo-electricity.

The thermo-electrical circuit also produces no effect upon the electrical condensation.

It is very remarkable that, notwithstanding all that has been mentioned, the thermo-electric circuit makes a prepared frog palpitate, like the hydro-electrical circuit. The communication between the extremities of the circuit and the nerves of the frog were made by means of platina wire, in order to guard against the influence of unequally oxidated surfaces.

Among circuits differing only by their length, the shortest has the greatest effect. A circuit of double length has not much more than half the effect. Complex circuits do not seem, therefore, at first sight, more efficacious than simple ones; the length being as much increased by the increased number of elements, as the effect should be heightened by the greater number of acting junctions; but comparing circuits of equal length whereof one has only two junctions, the other more, we see the true influence of the increase of acting junctions. Plate DXXIII. Fig. 13 represents a simple circuit of antimony *aa*, and bismuth *bb*, where only one of the junctions is to be heated or cooled. Fig. 14 represents a complex circuit of the same length, formed of two pieces *aa* of antimony, and two pieces *bb* of bismuth. Two of the junctions of the latter arrangement, situated on the extremities of one diagonal are here heated or cooled. Under the same changes of temperature, where the circuit, Fig. 13, made the needle to deviate about 22 degrees, that of Fig. 14, made it to deviate about 30 degrees. Fig. 15 and 16 represent two circuits of double the extent of the former, one simple, one having three alternations. By the same differences of temperature, by which the arrangement, Fig. 15, gave from 13 to 15 degrees, that of Fig. 16 gave nearly 32 degrees.

In several complex circuits, it is found that the heating or cooling of one junction only produces twice the angular deviations of that added by the addition of each active junction more. The effect of one active junction, when the others are at rest, is by experiment found to be twice the effect of all the arrangements, divided by the sum of the elements + one. The effect of each addition of a new active junction is only half this quantity, and seems even to be in a decreasing ratio, when the number of junctions is great.

The effect of thermo-electricity upon the multiplier is very instructive. Fig. 17 represents an arrangement formed by two pieces *b*, *b*, of bismuth, and one piece *a* of antimony. When the two free extremities of *b*, *b*, are put in communication with the extremities of the wire of the multiplier, and one of the junctions between *a* and *b* is heated or cooled, the needle of the multiplier is deviated, but very little; when one of the junctions is only cooled with ice, the effect is not so great as that of a disc of copper with one of silver, having common water as the liquid conductor. But when the extremities of *b*, *b*, are put in communication by means of a short piece of metal, the effect on the compass needle is considerable, whereas the effect of the hydro-electrical current of silver and copper, and even of silver and zinc, with common water as the liquid conductor, is scarcely sensible upon the same compass needle. This is a strong additional proof of the difficult transmission of thermo-electricity.

From all these observations we must conclude that the thermo-electric current produces an enormous quantity of electricity, but in a state of exceedingly small intensity. In order to conceive this well, it is to be remarked that the *intensity* of electricity is measured by the attractions and repulsions, whose force is in the inverse ratio of the squares of the distances, and that the *quantity* of electricity is measured by the number of equal surfaces which can be electrified by it to a certain degree of attraction and repulsion indicated by the electrometer. In the voltaic pile the intensity increases with the number of dics, the quantity with the surface of each of the discs. The greater the intensity the greater is the power of surmounting obstacles, or of penetrating through imperfect conductors; on the contrary, the greater the quantity the more perfect conductor is required to transmit it. The electricity produced by some thousand pairs of discs is able to penetrate a little lamina of air; that of some hundred pairs can at least penetrate through a considerable length of water; that of two pairs cannot easily be transmitted but by the solid conductors and some of the powerful liquid conductors.

The thermo-electrical current has a prodigious quantity of electricity in comparison with the hydro-electrical of silver, zinc, and water, but the intensity of the electricity is much greater in the latter; the electricity of the former is impaired by the resistance of the long multiplying wire, the electricity of the latter surmounting this resistance is on the contrary increased by the multiplying wire.

The complex thermo-electric circuit produces much more effect upon the multiplier, not only when the increased number of elements heightens the effect upon the compass needle, but still also when this increase does not augment the direct effect upon the needle. We must therefore conclude that the intensity increases with the number of the elements in the thermo-electrical as well as in the hydro-electrical current. It must therefore be possible to attain an intensity of the thermo-electrical current great enough for penetrating the liquid conductors, and producing the most considerable chemical effects. Still the construction of a thermo-electrical circuit of a great number of elements is very difficult, because the elements must be as short as possible in order to preserve the conducting faculty; but even the smallness of the distance between the heated and cooled parts must give way to a very speedy re-establishment of equilibrium. The best way seems to be, to produce the heating and cooling of the junctions by some continual current of hot and cold liquids.

A very easy manner of constructing thermo-electric batteries deserves to be mentioned. Fig. 18 represents it. The parts indicated by the odd numbers 1, 3, 5, represent copper slips, and those indicated by the even numbers 2, 4, 6, small bars of bismuth. All the junctions situated on one side of the dotted line *cd*, are to be heated, those on the other side are to be cooled. The extremities *a* and *b* are to be connected by a conductor. The number of elements may here be tolerably great.

That the intensity of the electro-magnetic current must increase with the temperature was to be presumed; but this is not a general law. Dr. Seebeck had already found some exceptions, and also Professor Cumming at Cambridge, who made his experiments without knowing those of Dr. Seebeck upon this subject. We shall not stop here to detail these experiments, as another philosopher, Mr. Becquerel, availing himself of the imposed instruments of research, and making a very ingenious application of them, has given us exact measures of the quantities here occurring.

It was supposed that the declination of the needle, produced by the electrical current is in the ratio of the sine of the angle of deviation. Though this is a consequence of the resolution of powers, he thought that, in a matter so little known as the magnetical effects of the electrical current, it might be advisable to examine the law of this measure by experiment, particularly with regard to the multiplier, where the current makes so many windings round the needle. In order to execute this plan, he formed his multiplier with four parallel and equal wires, covered with silk, and each making an equally great number of windings. Thus he had four multiplying windings about one frame. To the ends of each multiplying wire he soldered the ends of an iron wire, so that four thermo-electrical circuits, consisting of the copper wires of the multiplier and the iron wires were formed. When he wished to put one of these currents in activity, he cooled one of the junctions with ice, and heated the other in mercury. The junction was included in a thin bent glass tube, in order to guard it against the dissolving power of mercury. The mercury was heated by means of a lamp, somewhat above the temperature required, and when heated the lamp was taken away; thus the temperature remains for a short time stationary. In this manner he tried first the effect of one, then of two, three, or four of the multiplying circuits, and noted down the deviations produced, one of the junctions still being kept at the freezing point. Thus he found that one of the circuits gave, by 5° Centigrade or 9° Fahr. above the freezing point (41° Fahr.) a magnetic deviation of 0.65° French division, or 0,585° of common division of the arc. Two circuits gave by the same temperature twice 0.585°; three gave thrice, and four gave four times this quantity; whence he concluded, that when one circuit produces 4°.585 it has four times the power of that producing only 0°.585. It is easily understood that the greater angles of deviation could not be in the same ratio as the action; but this does not hinder us from drawing analogous conclusions. Thus by a difference of 180° Fah. one circuit gave the deviation 10,71° of the circle; but two circuits gave nearly the same (10°.575) by a difference of 90° Fah. But it is not in all temperatures that this proportion of the effect and temperature takes place; in very high degrees of heat he found that the effect of circuits of copper and iron did not increase so fast as the temperature. From the freezing point (32° Fah.) up to 284° Fah. the magnetical effect increases with the temperature. From this degree to 572° the magnetic power, though increasing with the temperature, still proceeds in a decreasing progression; and exposed to the immediate action of a lamp, the current is inverted. When none of the junctions is at the freezing point, the effect of the circuit is equal to the difference of the effect, which each of the two temperatures applied to one of the junctions, the other being at the freezing point, should give; thus, for instance, a circuit of iron and copper, when one junction is heated to 392° F., the other being at 32° F. has an intensity expressed by 37; but when the heat is only at 212°, the intensity is expressed by 22. The difference of these two numbers is 15, which is found by experiment to be the effect of the circuit, in which one junction is heated to 392° and the other to 212°. He found that a complex circuit of copper and iron produced an effect proportional to the number of elements, which is not the case, when the whole power of the circuit can be exerted, but is only so, when a very small part of the whole effect can be transmitted through a conductor, of such a length or feeble conducting faculty; that it requires much intensity of electricity, for being penetrated. Thus the observation of *Mr. Becquerel* proves, what had already been shown by less perfect experiments, *that the intensity of thermo-electricity increases as the number of the elements.*

Circuits of iron, with gold or silver, have likewise, as well as those which it forms with copper, a *minimum* of effect, by a certain elevated temperature, and in a still higher one their current changes its direction. In circuits of platina with gold, silver, lead, zinc, copper, and palladium, the differences of the intensities form an increasing arithmetical series.

Mr. Becquerel found that two pieces of platina form an active thermo-electrical current, when they are not of a perfectly equal nature. He cut through a piece of platina wire, and had one of the pieces drawn thinner; these two formed a thermo-electrical circuit. He maintains that the circuit is not efficacious unless a piece of some other metal is soldered to the one end of the wire, upon which statement we cannot but entertain some doubt, though Mr. Becquerel's authority is of no little weight. As Mr. Becquerel had found that the increments of the magnetic effect preserve the more their proportion to the increments of temperature, the more difficult the metal is in being melted, he considers a circuit of two unequal pieces of platina as a pyrometer. By means of this, he has tried the temperature of the different parts of a spirit-flame, and estimated the temperature of the blue flame bordering the white, at 1350° Centigr., or 2462° Fahr.; in the white part he estimated it to be 1080° Cent. or 1976° Fahr., and in the darker part of the flame to be 780° Cent. or 1426° Fahr. The last he considers as too high, because the other parts of the flame contributed to heat the junction.

Terrestrial Electro-Magnetism.

We cannot pass by this subject entirely, though we must treat it very briefly. Mr. Ampère, who thinks that magnetism consists only in transverse electrical currents, must, in consequence of his hypothesis, suppose an electrical current round the earth, from east to west. He thinks that the numerous strata, of which our globe is composed, may form considerable galvanic arrangements; still he supposes that the rotation of the earth cannot but have an effect on the electric currents around it. Mr. Ampère, in consequence of his system, admits no other magnetism of the earth than these currents. The opinion, that the earth is surrounded by electrical currents, though not strictly proved, is very probable. As for the galvanic arrangements which the earth is supposed to contain, there can be no doubt that the strata of the earth may form such combinations; but it is not at all proved that they produce a current from east to west. As far as the different currents formed by the strata, do not destroy the effect of each other, it is probable that their resultant effect lies nearly in the perpendicular; for the most general situation of the strata, is that one is placed above the other, generally with some inclination; but as this inclination may have all possible directions, the effects of the galvanic arrangements, (in so far as their action should have a horizontal direction, and thus be founded upon the inclinations,) must destroy each other, even if the inclination towards one side should be somewhat predominant; for galvanic arrangements combined in variable directions of their currents, produce a total effect much feebler than the difference of their positive and negative effects. The most efficacious excitation of electricity upon the earth appears to be produced by the sun. Its light passes round the globe from sunrise to sunrise, and produces evaporation, deoxidation and heat. Evaporation in contact with oxidable matters, produces electricity, as has already been asserted, but first exactly elucidated by the ingenious experiments of Mr. Pouillet. That the deoxidation which the sun produces during the day not only of the surface of plants, but also upon the surface of many other bodies, particularly when moistened, excites electric currents, is a well known galvanic fact. That the heat produced by the sunbeams, and also circulating from east to west, must produce an electrical current can scarcely be doubted; for though the surface of the earth be not composed of perfect conductors, and this resistance should make a common current insensible, the celerity of the circulation may, on the other hand, augment the effect to a degree sufficient for producing some effect upon the magnetic needle. Now, if it be admitted that the sun produces an electric current round the earth, this current must form a zone of considerable breadth, whose most intense part is situated in the plane of the circle, in which the sun seems to make its daily motion. Thus the situation of the most intense part of the zone varies with every day of the year. If we suppose that the earth had no other magnetism than that of this zone, a steel needle made magnetic by an artificial current, and then freely suspended, should take a direction towards the north and the south. Even a steel needle laid across the great natural current should be made magnetic, and suspended, take its direction accordingly. But the great current must also produce magnetism in the body of the earth itself; and as the magnetic effects of the inferior side of the current are opposite to those of the superior one, the magnetic poles of the earth become the opposite to those of the needle directed by the current, and should, therefore, if we for a moment suppose the electric zone destroyed, still give it the same direction. Thus the earth seems to have a constant magnetic polarity, produced, in the course of time, by the electrical currents which surround it, and a variable magnetism produced immediately by the same current. As the sun does not produce an equal effect upon water as upon solid bodies, the intensity of the current cannot be equal in all parts of a parallel circle, and therefore the direction of the needle cannot be perpendicular to the equator, nor can it form everywhere the same angle with the equator, for the lines of equal electromagnetic intensity must be twice bent by the influence of the two great masses of continent. The yearly and daily change of the electromagnetic zone, must occasion yearly and daily variations. As to the variations comprehended in greater periods, we might perhaps attribute them to a motion of the coolest points in each continent, which it appears cannot remain the same for ever, because the currents of warmer air must principally be directed towards such points; but we shall leave this research to future times, which may discover causes concealed from us, for explaining the great and secret revolution, which is continually performing in our globe.

It would be to offend against a love of truth, if we proposed these views as ascertained facts. Our researches upon the magnetism of the earth have been, during too short a time, directed by the electromagnetic discoveries, to enable us to give a complete theory of this subject. The great series of profound mathematical and philosophical investigations by which Professor Hansteen, at Christiana, has confirmed and improved the theory established by Dr. Halley, shows how many difficulties are to be surmouted. The accordance of this theory with observation, seems even to exclude the possibility of a new theory; but it must be remarked that this theory is only a mathematical representation of the phenomena, and does not pretend to be a physical one. In the same way as the mathematical laws of the celestial motions were discovered by Kepler, long time before their physical laws were superficially guessed by Hooke, or profoundly recognised and demonstrated by Newton, so the physical laws of the magnetism of the earth may now, perhaps, be fairly conjectured, and in a future age be brought to the requisite degree of perfection. Still we hope that these views will recommend themselves to farther investigation, as they would, if proved, have the great advantage of showing an intimate connexion between an extensive series of phenomena upon the earth and those of the universe.

Some Theoretical Considerations.

The question has during late years been often proposed, *whether or not magnetism and electricity* *are identical.* There has been a good deal of misunderstanding in the discussions on this subject. Mr. Ampère pretends that the discoverer of electromagnetism, though he had earlier admitted the identity of these effects, has, in his first paper upon electromagnetism, denied it. We must here remark, that the words have two acceptations; in one of these Professor Oersted is perhaps the most earnest supporter of this identity, in the other he is a no less decided opponent of it. His opinion is, that all effects are produced by one fundamental power, operating in different forms of action. These different forms constitute all the dissimilarities. Thus, for instance, pressure upon the mercury of the barometer, wind and sound, are only different forms of action of the same powers. It is easy to see that this fundamental identity extends to all mechanical effects. All pressures are produced by the same powers as that of air; all communications of motion, and likewise all vibrations, owe their origin to the same expansive and attractive powers, by which each body fills its space, and has its parts confined within this space. This fundamental and universal identity of mechanical powers has for a long time been more or less clearly acknowledged; but the effects which have hitherto not been reduced to mechanical principles, seemed to be derived from powers so different, that the one could scarcely be deduced from the other. The discoveries which began with galvanism, and which have principally illustrated our century, led us to see the common principles in all these actions. Two or three years before the beginning of the century, Ritter had, by means of the simple galvanic arrangement, pointed out and distinctly stated the principle of the electro-chemical theory; still his ideas were not generally admitted before the discovery of the Voltaic pile had struck the mind of the experimental philosophers with more palpable facts. That heat and light are produced by the union of the opposite electrical powers, had been acknowledged by the Swedish philosopher Wilcke, a cotemporary of Black, but this view was far from being generally admitted. Winterl brought it forward in 1800, and was supported by Ritter and Oersted. The last investigated the subject farther, and developed some of the principal laws of the generation of heat by the electrical and chemical powers.* He proved that the electrical powers are present in all cases where heat and light are generated. That magnetical effects can be produced by the same powers need not here be mentioned. As the chemical powers give rise to expansion and contraction, it appears that their nature is not different. Thus acknowledging the fundamental and universal identity of powers, effects must be considered as different, when their form of action differs, and therefore magnetism, in this acceptation of the term, is far from being identical with electricity. It would likewise be erroneous to pretend that all chemical effects are produced by electricity; but the truth seems to be, that the chemical effects are produced by the same powers which, in another form of action, produce electricity. The name of *electro-chemical* theory, given to the modern chemical system, seems, therefore, less admissible than the denomination of *dynamico-chemical* theory, proposed by Oersted so early as 1805. It is still true, that the common electro-chemical theory deserves its name, as it does not go out of the limits of an electrical view of the subject. This theory stops throughout in generalities, and gives no account of the disparities of the effects. We will not pretend that a sufficient dynamico-chemical theory has hitherto been pointed out; we must even admit that our knowledge is not ripe enough for this purpose; but we think that some laws, accounting for the disparities, have been pointed out in the work above quoted, upon the identity of electrical and chemical powers (viz. fundamental powers), and that the ideas therein explained deserved attentive examination. The dynamico-chemical theory must still remain very imperfect, until it is decided if the powers acting in magnetism, electricity, heat, light, and chemical affinities are to be ascribed to vibratory, circulating, and other internal motions or not. That these effects do not pass without the most remarkable internal motions, appears from the experiments upon light and upon electro-magnetism. The electrical current is a system of rotative motions, upon whose directions, perhaps, all the disparity of positive and negative electricity depends. It is not improbable that even magnetism involves some rotations, and thus the opinion of Mr. Ampère comes to agree with ours, at least in this point. When the transmission of the electrical current through liquid bodies is accompanied with a chemical decomposition, it seems necessary to admit that the substances styled electro-positives and electro-negatives, must rotate in opposite directions, and we may suppose that their neutralizing powers are connected with the propensities to those opposite rotations. The new discoveries, in short, reveal to us the world of secret motions, whose laws are probably analogous to those of the universe, and which deserve to be the subject of our most earnest meditations.

APPENDIX.

AMERICAN SILK.

IT is now well ascertained that the white mulberry, considered as the best food for silk worms, will grow and thrive in every part of the United States, and it is even believed by many, that the red mulberry (*morus rubra*) indigenous to this country, might supply its place. Experiments, however, have not sufficiently shown to what extent this is to be admitted. It appears that the worm feeds with equal avidity on the one as on the other, and that he does not show any preference to either when both are presented to him at the same time. But some say that there is a difference in the silk produced by that insect when fed on the leaves of the red mulberry; that it contains more gum, and consequently is harder and more difficult to reel than the cocoons of worms fed on the leaves of the white mulberry. We must leave it to time and experience to decide this question. In the meantime, we are happy to state, that the plantation of the white Italian mulberry is rapidly extending itself through almost every state in this Union, and that, from its abundance, it will probably before long supersede every other tree for the feeding of silk worms.

It is also an admitted fact, that the climate of this country, from north to south, is favourable to the raising of silk worms. Experiments have been made even in Vermont and Maine, and they have succeeded. It is well known, that for the space of seventy years, silk worms have been raised in great quantities in the state of Connecticut, particularly in the counties of Windham and Tolland, which abound in white mulberry trees. The farmers of those parts extract the silk from the cocoons, and manufacture it into sewing silk, which they dispose of in the circumjacent country by way of barter, and it even serves them as a circulating medium, the legislature of that state having provided wise regulations to prevent fraud and imposition. That silk, however, is not merchantable in our sea port towns, as it is neither equal to imported silk, nor can it be afforded at the same price. Such as it is, however, it serves the purposes of the country people, which is truly astonishing, when we consider that it is made without any other machinery than the common spinning wheel, and by persons unskilled in the arts of reeling and throwing or twisting the material, which in Europe constitute different professions, requiring long practice and a regular apprenticeship. Too much praise cannot be given to the industry and ingenuity of the Connecticut women, by whom this labour is exclusively performed. That state is destined to become rich by the silk culture and manufacture, when better methods and the proper instruments shall have been introduced among them. At present it cannot be said that this branch of industry is to them a source of riches; it has been remarked, on the contrary, that the silk districts are comparatively poor.

The culture of silk was in the view of the British government from the earliest period of the colonization of this country. King James I. who hated tobacco, the staple commodity of Virginia, gave orders to the governor of that colony to take measures to introduce the culture of silk, in hopes that it might supersede what he called the nauseous weed. Silk worms' eggs, white mulberry trees, and printed instructions were sent over and distributed. In 1623, the Colonial Assembly directed the planting of mulberry trees, and a fine was afterwards imposed on every planter who should not plant, at least, ten such trees for every hundred acres of land that he possessed, while a premium was offered of ten thousand pounds of tobacco to those who should export two hundred pounds worth of raw silk. It does not appear that any was ever exported, or even that any measures were taken to instruct the people in the art of spinning or reeling the silk from the cocoons, so as to make it merchantable; nevertheless, mulberry trees were generally planted, and it is said that they now abound in the eastern part of that state.

South Carolina, in early times, made some efforts to introduce the culture of silk, but those efforts were partial, and were not attended with much success. Some patriotic ladies sent raw silk of their own raising to England, where it was manufactured into stuffs. But the quantity was small, 251 lbs. of it only having been entered at the custom house in the course of six years. The thing did not proceed farther. The silk being of course very imperfectly reeled, its waste must have been considerable, and the proceeds of it not being equal to the labour and expense that it occasioned, discouragement necessarily followed.

The colony of Georgia proceeded in a more cautious manner, and their success was proportionate. Upon its first settlement in 1732, the culture of silk was contemplated as a principal object of attention, and lands were granted to settlers upon condition that they planted one hundred white mulberry trees upon every ten acres when cleared, and ten years were allowed for their cultivation. All this was excellent; but what was better still, is that a native of Piedmont was engaged to instruct the people in the art of rearing the worms and *winding the silk*. The colonial trustees undertook the management of the business, and they succeeded so well that before the year 1750, large quantities of raw silk had been exported from Georgia into England. In that year a public filature was erected by order of these trustees, and the exports of silk from the year 1750 to 1754 inclusive amounted to $8,880. In the year, 1050 lbs. of raw silk were produced at the filature, which supposes the reeling of at least 8000 lbs. of unstifled cocoons. In the year 1758, that building was consumed by fire with a quantity of silk, and 7040 lbs. of cocoons. M'Call, the historian of Georgia, relates, that in the year 1759, this colony exported upwards of 10,000 lbs. of raw silk, which sold for two or three shillings per pound higher than that of any other country. But this fact may well be doubted, as it is in direct contradiction to authentic records which will be presently mentioned.

One would naturally suppose that the production of raw silk as an article of exportation had been established in Georgia on a solid and lasting foundation. Yet it began to decline, for what reason we know not, many years previous to our revolution. We are informed by an official statement of William Brown, comptroller of the customs at Savannah, that between the years 1755 and 1772, a period of seventeen years, including the year 1759, no more than 8829 lbs. of raw silk were exported from that port, something less than had been before exported in five years. This branch of industry, however, lingered until some time after the peace with Great Britain. The last we hear of silk in Georgia is in the year 1790, when upwards of 200 lbs. weight of the raw article were purchased for exportation at 18*s.* and 26*s.* per pound, we presume of the currency of the country, (4*s.* 8*d.* to a dollar), which makes those prices equal to about $4 and $5,50 per pound, a very high price even at this day, when it is known that the current prices of Italian raw silks in the London market are from 9*s.* to 22*s.* sterling.

We are at a loss to conceive how a branch of industry which appeared then to be in so flourishing a state, can have suddenly disappeared from a state where it had been introduced in a manner so well calculated to ensure its permanency. We have been told that it was owing to the rage for the culture of cotton, which began about that time to take possession of the minds of the inhabitants of the southern states. This is the most rational way of accounting for an event which Georgia may long have reason to lament. We must add, also, that before the revolution, the business was monopolized by the trustees who had the management of the colony, in which there was but one filature of silk, which probably, after the war, fell into the hands of those who had neither the means nor the capacity to turn it to advantage. If the art of reeling silk had been generally disseminated through the state, it would, no doubt, have been preserved, whereas it appears to be entirely lost.

In the year 1770, on the recommendation of Dr. Franklin, who was then in England, the American Philosophical Society undertook to promote the culture of silk in Pennsylvania. Money was raised by subscription and a filature established at Philadelphia, to which an end was put by the revolutionary contest. Unfortunately, we have no details respecting this filature, its establishment, its progress, or its end. It is said by some that a person skilled in the art of reeling silk from the cocoons, was obtained from France and placed at the head of it, as director. But this fact is not sufficiently ascertained. It does not appear that any raw silk was exported from the port of Philadelphia.

During the revolutionary war, of course, (except, perhaps in Connecticut and for a while in Georgia,) no attention was paid to the culture of silk. After the peace, other objects engrossed the attention of the public. About the year 1790, Mr. Aspinwall of Connecticut, made fruitless efforts to introduce this branch of industry in Pennsylvania and New Jersey; he succeeded no farther than the planting in those states some thousand of mulberry trees. It does not appear that he was aware of the importance of the art of reeling; indeed, few persons, if any, in the country, seem at that time and long afterwards to have carried their views farther than the converting the raw material into sewing silk, as was done in Connecticut. The variety of arts, whose concurrence is required for the manufacture of silk stuffs, was far from being generally or correctly understood.

From time to time, however, some patriotic writers endeavoured, through the newspapers, to draw the attention of the public towards the culture of silk; but those publications produced little effect. It was recommended to the citizens to plant mulbury trees and raise silk worms; but nobody told them what they should do with the cocoons that those silk worms should produce. The example of Connecticut was sometimes set before them; but that was not very encouraging. A few pounds of domestic sewing silk were hardly worth the labour which the cultivation of the raw material would require, and indeed, it might have been observed that the counties of Tolland and Windham, where the greatest quantity of silk was raised, instead of being the richest in the state, were, as we have said, comparatively poor.

Still, there were reflecting minds, who, casting their eyes over the southern parts of the continent of Europe, particularly Italy and the south of France, and paying attention to the immense riches which they derived from the silk culture and manufactures, and the great profits which England obtained from the latter alone, felt an ardent desire that the United States should participate in these blessings, for which they were so well fitted by their climate, and the industry and activity of their citizens. But the difficulty was how to go to work to produce the desired effect.

At last an enlightened and patriotic citizen of Pennsylvania, Charles Miner, Esq. of West Chester, who for several years had been actively engaged in promoting the culture of silk in his immediate district, and who was then a member of the House of Representatives of the United States, had the happy idea of submitting the subject to the consideration of the national legislature, who he thought might devise effectual measures to attain the object he had in view. On the 29th of December 1825, the house on his motion resolved: "that their committee on agriculture be instructed to inquire whether the cultivation of the mulberry tree and the breeding of silk worms, for the purpose of producing silk, be a subject worthy of legislative attention, and should they think it to be so, that they obtain such information as may be in their power respecting the kind of mulberry tree most preferred, the best soil, climate and mode of cultivation, the probable value of the culture, taking into view the capital employed, the labour and the product; together with such facts and opinions as they might think useful and proper—and further, that the same committee inquire whether any legislative provisions are necessary or proper to promote the production of silk."

We have already observed that at that time the people were not generally aware of the difficulty of the art of spinning or reeling the silk from the cocoons, as is practised in Europe; the most that was thought requisite by the best informed, was the importation of a few machines to facilitate the labour; as to the skill, it was thought that it would be as easily acquired as was done in the article of cotton, which our people had easily learned to prepare for exportation and to employ in manufactures. Indeed, many believed that the women of Connecticut, who could make sewing silk, were sufficiently possessed of that art, and that instruction from abroad was not required, or if it were, it could easily be obtained from the books that had been written on the subject in France and elsewhere.

Under these impressions, the committee met and acted. On the 2d of May 1826, they made a full report, in which they gave a luminous view of the importance of the culture of silk to the United States. They showed that in five years, 1821—1825, we imported upwards of 35 millions of dollars worth of silk goods, of which we exported not quite 8 millions, leaving 27 millions to be paid by our citizens, and that in the last of those years we had imported ten millions worth of silks and exported only five millions of bread stuffs. After this strong exposition, and stating a variety of facts relative to the then existing state of the culture of silk in the United States, they recommended the following resolution, which the house adopted without debate: "*Resolved*, That the secretary of the treasury cause to be prepared a well digested manual, containing the best practical information that can be collected on the growth and *manufacture* of silk, adapted to the different parts of the Union, containing such facts and observations in relation to the growth and manufacture of silk in other countries as may be useful, and that the same be laid before congress at their next session."

The secretary of the treasury at that time was the Hon. Richard Rush, of Pennsylvania. It is to be regretted that he was not instructed personally to inquire and obtain information from those parts of Europe where the culture of silk most flourishes, and where the manufactures from that material have attained their highest perfection; he would have been told that the spinning of the raw silk, whether it was intended to be exported abroad or manufactured at home, was the first thing to be attended to, as it would promote the silk culture, by opening a market for the cocoons; he would have been told also, that it was a difficult art, that required instruction and experience, and he would no doubt have proposed to congress the best means to introduce that art among us; but as he was only ordered to cause a manual to be prepared, he performed that duty by committing the work to Dr. James Mease of Philadelphia, a member of the American Philosophical Society, who was known to have paid much attention to the general subjeet.

The manual was in consequence compiled by that gentleman, and on the 11th of February 1828, it was reported by the Secretary to the House of Representatives, who ordered 6000 copies of it to be printed for the use of the members. The Senate also ordered a number of copies to be printed, so that the work was disseminated far and wide. It contained full instructions for the planting of mulberry trees and the raising of silk worms, the latter chiefly extracted from the great work of Count Dandolo, whose method, though perhaps well suited to the meridian of Italy and France, is much too troublesome for that of this country. Experience indeed has shown, that silk worms may be raised among us without the aid of artificial heat, which Count Dandolo, and after him the author of the manual, recommends as indispensable. Our farmers would never submit to the numerous minute observances which that work requires to bring the cocoons to perfection.

All these proceedings, emanating from the highest authority in the nation, gave a strong impulse to the silk culture in the United States. Mulberry trees were planted in various places, nurseries were formed in the neighbourhood of our large towns; foreign works were translated, extracted from and abridged; in short, a considerable zeal was excited throughout the Union. A society was formed in the city of Philadelphia, in the year 1828, "for promoting the culture of the mulberry tree and the raising of silk worms." Although there were among them many rich individuals, their joint funds were not considerable; they therefore very properly confined themselves at first to the granting of premiums.

Their views, however, soon extended beyond what appears to have been their original plan, and desirous of adding example to precept, and to introduce into Pennsylvania the making of sewing silk, as practised in Connecticut, they endeavoured to obtain from that state a woman qualified to instruct other females in that branch of industry, in which having failed, they turned their thoughts to Europe, and wrote to a correspondent at Marseilles to procure for them and send over a person sufficiently qualified to reel the silk from the cocoons and convert it into sewing silk. This order was not easy to be executed, as the reeling of silk is performed by women, under the direction of an overseer, called a director of a filature, and the making of sewing silk from the raw material after it is reeled, belongs to a class of mechanics called silk-throwsters, who employ a great deal of expensive machinery. Of course a person competent to both could not easily be obtained. After, however, many fruitless inquiries, the agent found a young man, who, on examination, proved to be adequate to the task required. This young man, named John D'Homergue, was the son of an eminent silk manufacturer at Nismes, who had brought him up to the various branches of his profession, in hopes that he should succeed him in his establishment. The young man, however, when he came to the age of manhood, chose to follow the profession of a lawyer, and at the time that we speak of, was the editor of a newspaper in the city of Marseilles. The agent engaged him to come over to this country, telling him, as was really the truth, that the company which had sent for him consisted of some of the richest and most respectable men in the city of Philadelphia. He had, indeed, no instructions to make a specific bargain with him, but there was no doubt that on his arrival every thing would be done to his satisfaction. Mr. D'Homergue in consequence embarked, and arrived in the city of Philadelphia in the month of May 1829.

It is very clear that Mr. D'Homergue had no idea of our numerous associations for the *promotion* of various things connected with the general welfare of the country. He thought of a mercantile company, associated for the purpose of carrying on together some lucrative branch of industry, and provided with means adequate to their object. He found, on the contrary, excellent patriots, but poor manufacturers. He found no preparation made for a silk establishment, no place provided for carrying on the operations, no machinery, except one single Piedmont reel, which had been imported by one of the members. In short, he met with the most complete disappointment.

This society, however, by being the means of inducing Mr. D'Homergue to come to the United States, rendered an important service to their country, the happy consequences of which will be long felt, whatever may become of the individual hereafter. He has contributed much to enlighten the public mind on the subject of the culture and manufacture of silk, which he published in the year 1829, and which have drawn the attention of the national legislature. There is now a bill before the House of Representatives of the United States, reported by their committee on agriculture on the 12th of March 1830, the object of which is to establish, at Philadelphia, a normal school, in which Mr. D'Homergue is to be employed in instructing sixty young men, from the different states of the Union, in the art of reeling silk from the cocoons, an art which requires practical instruction and experience, and without which the culture and manufacture of silk can never be effectually carried on in this country. The pressure of other business has hitherto prevented that bill from being taken into consideration; but its plan seems to be generally approved, and there is great reason to hope that it will finally receive the legislative sanction. This is the more probable, that Mr. D'Homergue, during the two years that have elapsed, has been unceasing in his exertions to promote his favourite object. A filature has been established under his direction in the city of Philadelphia, in which more than twenty women have been more or less instructed in the art of reeling silk from the cocoons. Several parcels of raw silk from that filature have already been exported to Europe, where they have been pronounced to be a fair beginning, and to give great hopes for the future. Of that silk, Mr. D'Homergue has wove two flags, bearing the colours of the United States, each twelve feet long and six feet broad, one of which has been presented to the House of Representatives of the United States, and the other to the Legislature of Pennsylvania, who have both condescended to give to those specimens of American industry, a conspicuous place in the halls of their sittings.

In the meantime, correct information on the subject of the various arts connected with the culture and manufacture of silk, has been widely disseminated by a great number of writings throughout the United States, and artists of various descriptions (but no reelers or spinners of silk from the cocoons) have migrated from Europe to our shores. There are now several throwsting mills in operation in various parts of our country, that work on foreign raw silk, which is now imported in great abundance. It is hoped that, if the plan before congress shall be adopted, it will not be long before our manufacturers shall be supplied with the domestic material, and that silk will thus become one of the principal sources of our national riches and prosperity.

DUPONCEAU.

GENERAL EXPLANATION

OF THE

PLATES BELONGING TO VOLUME SEVENTEENTH

OF THE

AMERICAN EDITION

OF THE

NEW EDINBURGH ENCYCLOPÆDIA.

PLATE CCCCLXXXVII. No. I.

Fig. 1, 2. Represents Dr. Wollaston's Dip Sector.
Fig. 3, 4, 6. Are Diagrams explanatory of the principle of Hadley's Sextant.
Fig. 5. Is a representation of this Sextant.
Fig. 8. Is a Diagram explanatory of the principle of Amici's Sextant. See Fig. 10, Plate CCCCLXXXVII, No. II.
Fig. 9. Is a drawing of this Sextant.

PLATE CCCCLXXXVII. No. II.

Fig. 7. Shows the method of using Hadley's Sextant.
Fig. 10. Is a Diagram illustrative of Amici's Sextant.
Fig. 11. Represents Troughton's artificial Horizon.
Fig. 12. Represents Dollond's artificial Horizon.
Fig. 13. Shows the method of using the artificial Horizon.
Fig. 14. Is the cover of the artificial Horizon.
Fig. 15. Represents Serson's Nautical Top.
Fig. 16, 17. Represents Troughton's Level Sextant.
Fig. 18, 19. Represent Mr. Adam's Nautical Eye Top.
Fig. 20, 21. Represent Dr. Brewster's improvement upon it.

PLATES CCCCLXXXVIII to CCCCXCV.

Are Diagrams illustrative of the principles of Ship-building.

PLATE CCCCXCVI.

Fig. 1—4. Contain a comparative view of the construction of square and circular sterns.

PLATE CCCCXCVII.

Fig. 1—9. Show the advantage of circular over square sterns.

PLATE CCCCXCVIII.

The principal figure is the disposition of the frame of an 84 Gun ship, according to the improved construction of Sir R. Seppings.
Fig. 1—7. Are a perspective view, plan, &c. of a longitudinal section of a 74 Gun ship.

PLATE CCCCXCIX.

Fig. 1, 2. Is a Draught for Building a Ship of 84 Guns.

PLATE D.

Fig. 1—5. Represent Sir R. Seppings's improvements on Ships in the Mercantile Navy.

PLATE DI.

Fig. 1, 2. Show the old principle of framing the stern with transoms.

Fig. 3—6. Are Diagrams illustrative of the theory of the paddle wheels of Steam Boats.

PLATE DII.

Fig. 1. Represents Mr. Morton's Portable Slip, or apparatus for hauling vessels out of water to be repaired.

PLATE DIII.

Fig. 1—96. Are Representations of the particles of Snow seen through a Microscope according to the Observations of Mr. Scoresby.

PLATE DIV.

Fig. 1—3. Show Dr. Ure's apparatus for measuring the elasticity of Steam.

Fig. 4, 5, 6. Represent the first Steam Engine invented by the Marquis of Worcester, according to the idea of Mr. Scott of Ormiston.

Fig. 7. Represents Dr. Papin's first Steam Engine.

Fig. 8, 9, 10. Contain a representation of Savery's Steam Engine.

Fig. 11. Represents Dr. Papin's second Steam Engine.

PLATE DV.

Fig. 1, 2. Represent Dr. Desagulier's improvement on Savery's Engine.

Fig. 3. Shows Mr. Kier of Birmingham's improvement on Savery's Steam Engine.

Fig. 4, 5. Contain a view of Newcomen's Atmospheric Engine.

PLATE DVI.

Fig. 1, 2. (marked Fig. 6, 7 of Plate DV). Represent Beighton's Steam Engine.

Fig. 3. (marked Fig. 1 in text). Is a view of Leupold's High Pressure Engine.

Fig. 4. (marked Fig. 2 in text) Shows Blakey's improvement on the Steam Boiler.

Fig. 5. (marked Fig. 3 in text) Shows Mr. Watt's mechanism for opening and shutting the Nozle Valves.

PLATE DVII.

Represents Mr. Watt's Reciprocating Engine of 1788. In p. 368 margin, read Plate DVII, in place of DVIII.

PLATE DVIII.

Fig. 1. Represents the Albion Mill Steam Engine erected by Messrs. Boulton and Watt.

Fig. 2. Shows the Regulator Box.

Fig. 3. Is a Diagram explaining the principle of the parallel motion.

Fig. 4. Shows the construction of the Throttle Valve.

PLATE DIX.

Fig. 1. Represents Mr. Hornblower's Double Cylinder Engine.

Fig. 2, 3. Show Hornblower's Skeleton Valve.

Fig. 4. Represents Trevithick's High Pressure Engine.

Fig. 5. Shows Trevithick's Boiler.

Fig. 6, 7. Show the principle of the Steam Engine proposed by Mr. Perkins.

Fig. 8—13. Represent a Steam Engine without a Boiler, the invention of Mr. Scott of Ormiston.

Fig. 14—18. Show Mr. Gurney's Tube Boiler.

Fig. 19, 20. Show Mr. Gurney's Condenser.

Fig. 21. Represents Mr. Murray's Sliding Valve.

Fig. 22. Represents Mr. Sim's Valve.

Fig. 23. Represents Cartwright's Piston.

Fig. 24. Represents Jessop's Piston.

PLATE DX.

Fig. 1, 2. Are drawings of Jonathan Hull's Steam Boat, invented in 1735.

Fig. 3. Is an enlarged view of the mechanism of Hull's reciprocating motion.

Fig. 4. Is an external view of a Steam Vessel.

Fig. 5. Represents the Engine erected by Mr. Gutzmer for the Royal George Steam Boat.

Fig. 6, 7. Are an Isometrical view and section of the Steam Boat Engine.

Fig. 8. Represents Gurney's Steam Boat Engine.

Fig. 9, 10. Show the revolving Paddles of Mr. Oldham, compared with the common Paddles.

PLATE DX. No. II.

Fig. 1. Represents the Steam Boat invented by John Fitch.

Fig. 2. Represents the Bridge over the Delaware River near Trenton.

Fig. 3. Represents Oliver Evans's Columbia Steam Engine.

PLATE DXI.

Fig. 1—4. Represent Messrs. Losh and Stephenson's Rail Road and Steam Carriage.
Fig. 5, 6. Are drawings of a Steam Carriage Engine.
Fig. 7—10. Represent Mr. James Watt's original apparatus for Drying by Steam.

PLATES DXII, DXIII, DXIII, No. II.

Are illustrative of the principles of Stenography.

PLATE DXIV.

Fig. 1—5. Represent Professor Barlow's apparatus for measuring the Strength of Materials.

PLATES DXV, DXVI, DXVII.

Are illustrative of the article Surgery, and are minutely described in pages 597, 598 of this volume.

PLATES DXVIII, DXIX, DXX.

Are illustrative of the article Tactics, *Naval*, in this volume.

PLATE DXXI.

Fig. 1. Shows Dr. Hooke's Telegraph.
Fig. 2. Represents M. Chappe's Semaphore.
Fig. 3. Mr. Edgeworth's second Telegraph.
Fig. 4. Rev. Mr. Gamble's Shutter Telegraph.
Fig. 5. Rev. Mr. Gamble's radiated Telegraph.
Fig. 6. Dr. Garnet's Telegraph.
Fig. 7. Lord George Murray's Telegraph.
Fig. 8. French Semaphore Telegraph.
Fig. 9. Mr. Edgeworth's one-armed Telegraph.
Fig. 10. French Coast Telegraph.
Fig. 11. Colonel Pasley's polygrammatic Telegraph.
Fig. 12. Colonel Pasley's improved Telegraph.
Fig. 13. Colonel Macdonald's Shutter Telegraph.
Fig. 14. Sir Home Popham's Semaphore.
Fig. 15. Colonel Macdonald's Ball and Shutter Telegraph.
Fig. 16. Colonel Macdonald's 6 ball and 3 figure Telegraph.
Fig. 17. Colonel Pasley's Universal Telegraph.
Fig. 18. Do. Do. for nocturnal signals.
Fig. 19, 20. Show the construction of the above Telegraph.
Fig. 21. Shows the Telegraphic signs for this Telegraph.

PLATE DXXII.

Fig. 1—6. Illustrate the Electro-magnetic discoveries of Professor Oersted.
Fig. 7. Shows Berzelius's idea of four magnetic Poles in the uniting wire.
Fig. 8. Shows Professor Oersted's apparatus for deciding this question.
Fig. 9. Professor Schweigger's Multiplier.
Fig. 10. M. Nobili's improved Multiplier.
Fig. 11. Professor Oersted's Multiplier.
Fig. 12. Is Mr. Faraday's apparatus for causing a Magnet to revolve round an electrical Conductor.
Fig. 13. Is Mr. Faraday's apparatus for causing a Magnet to revolve round its own axis by means of an electrical current.
Fig. 14. Illustrates the development of magnetism in other bodies by the electrical current.
Fig. 15. Method used by MM. Arago and Ampere.
Fig. 16. Shows the apparatus used in M. Ampere's experiments on the effects of the magnet on the uniting wire.
Fig. 17. Is an apparatus in which the earth's magnetism gives a direction to the uniting wire.
Fig. 18. Shows M. Ampere's application of the principle of the multiplier to move the uniting wire, as somewhat modified by Professor Van de Roos.

PLATE DXXIII.

Fig. 1. Is another apparatus invented by M. Ampere for the same purpose.
Fig. 2. Is M. Ampere's apparatus improved by Mr. Marsh for showing the magnetical effect of the earth on the uniting wire.
Fig. 3. Is an apparatus for causing a movable uniting wire to revolve round a magnet.
Fig. 4. Is Ampere's revolving apparatus.
Fig. 5. Is Professor Barlow's revolving apparatus.
Fig. 6. Is Professor Pohl's revolving apparatus.
Fig. 7—10. Illustrate M. Ampere's discoveries respecting the mutual action of electrical currents.
Fig. 11. Is an apparatus for illustrating M. Ampere's doctrines.
Fig. 12—17. Are illustrative of Dr. Seebeck's discovery of electro-magnetic currents produced by heat.
Fig. 18. Shows the method of constructing Thermo-electric batteries.

END OF VOLUME SEVENTEENTH.

ERRATA.

Page 670, first column, 23d line from bottom, for *Hagersville* read *Rogersville*.
Page 671, first column, 2d line, for *remains* read *remain*.
Same column, 5th line, for *Atchabalaya* read *Atchufalaya*.
Same column, article Tequendama, for *Stanblack* read *Stauback*.
Same article, for *Catskill* read *Caterkill*.

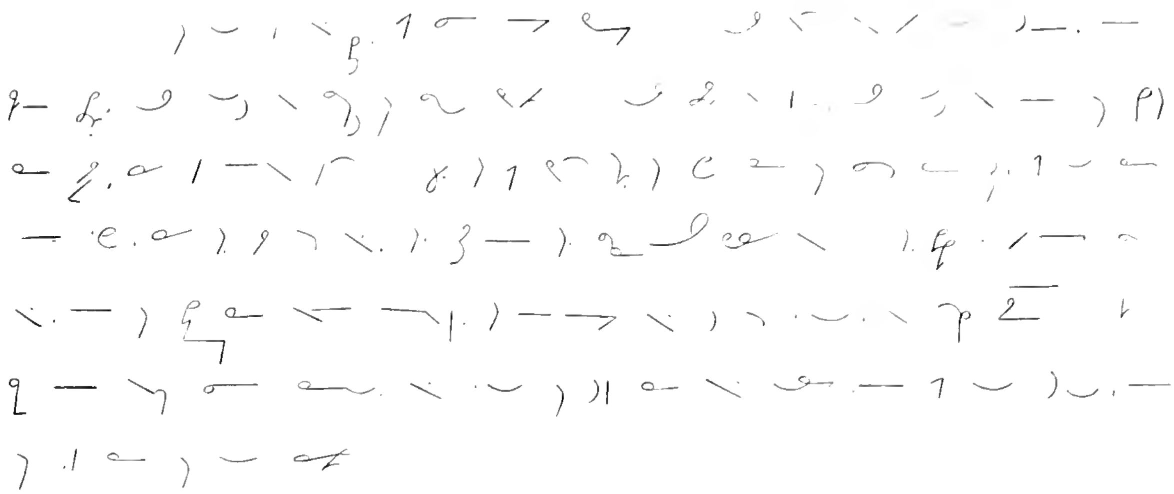
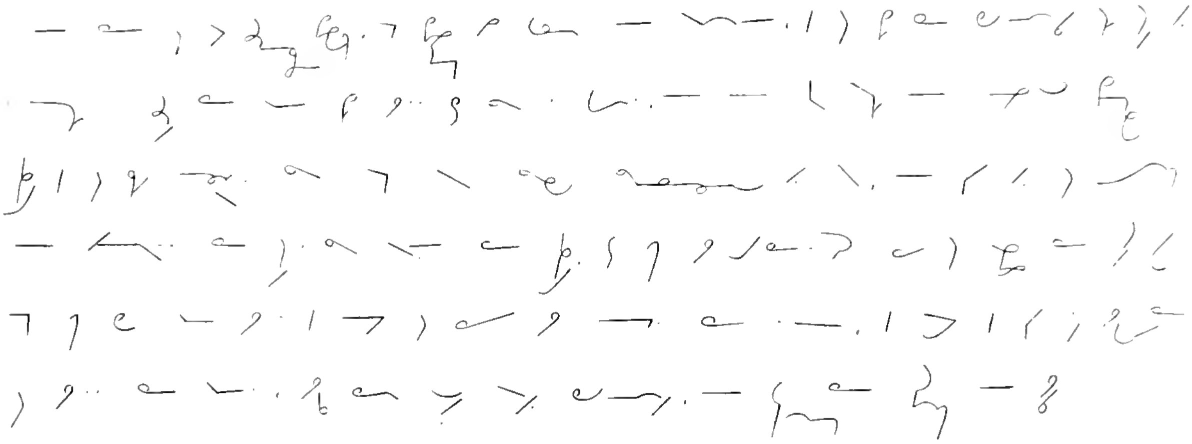
THE ALPHABET Fig 1
b, be, bee, by, buy
d, do, does, doth
f, if, of, off
g, egg, god, good
h, but seldom used as the aspirate can be added in reading
k, king
l, ill, will, well, lord
m, man, him
n, in, inn, on, and
p, up
r, err, or, are
s, is, us, as, ass
t, at, it
v, has, hath, have, how
w, was, were
x, ax, ox
y, ye, you
Fig. 2
con, can, came.
com, come, came.
count, account.
ante, anti, against.
enter, inter, entire
trans, tran, train
serve, service, servant.
multiple, multiply, multitude.
struct, strike, struck.
st, state, saint
circle, circum, circumstance
world, globe
for, fore, far, fare, fair
from
with, within, without
triangle, trinity, together
together with.
scrip, scribe, ascribe.
ble, able, enable.
Fig 2 continued
clude, cloud, clude
ness
ing, thing
cle, ple, kill, call, coal
ct, act
one, one another
th, the, thee
this, these
that, those
wh, who, what
he
she
they.
sh, shall, shell
ch, child, children
Christ, Christ Jesus
cross.
Fig. 3.
1st say, see, sigh, so, su
2d na, ne, nigh, no, nu
3d bow, fowl, fail, toil
4th act, action, ten, tention.
5th nation, session, mission, motion, illusion
6th a come, come over.
b good, good, good
c back, back and fore or back and breast
d king, kingdom, la, lament
e law, lawful, brimfull
f the ship was full of goods
wor, worship
g before, behind, before and behind, or before and after
h a, awe, O, oh, owe
i s, Sir, n, nor, l, ler
k t, tr, tart.
l ba, ball, tie, toil
m n, name

EXAMPLES

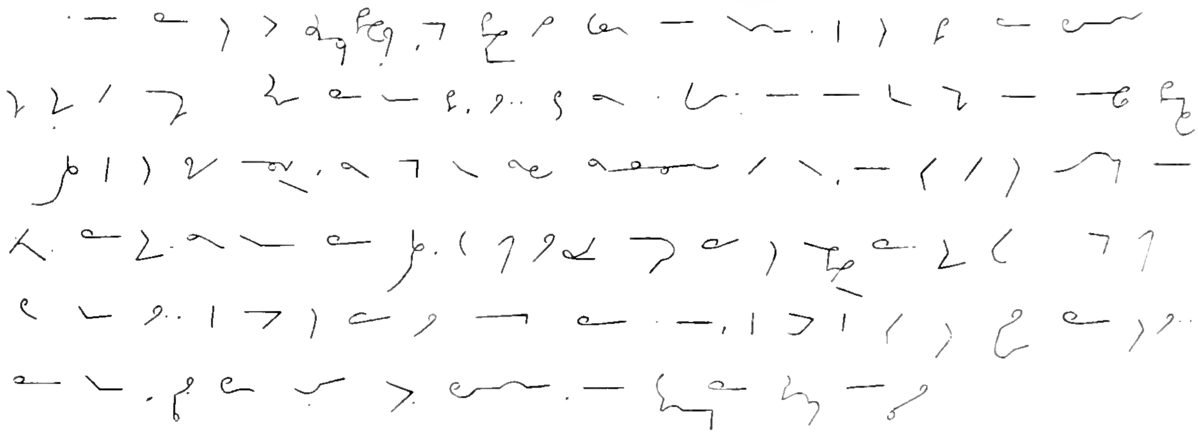
The 23rd Psalm



From Doctor Blair's Rhetoric

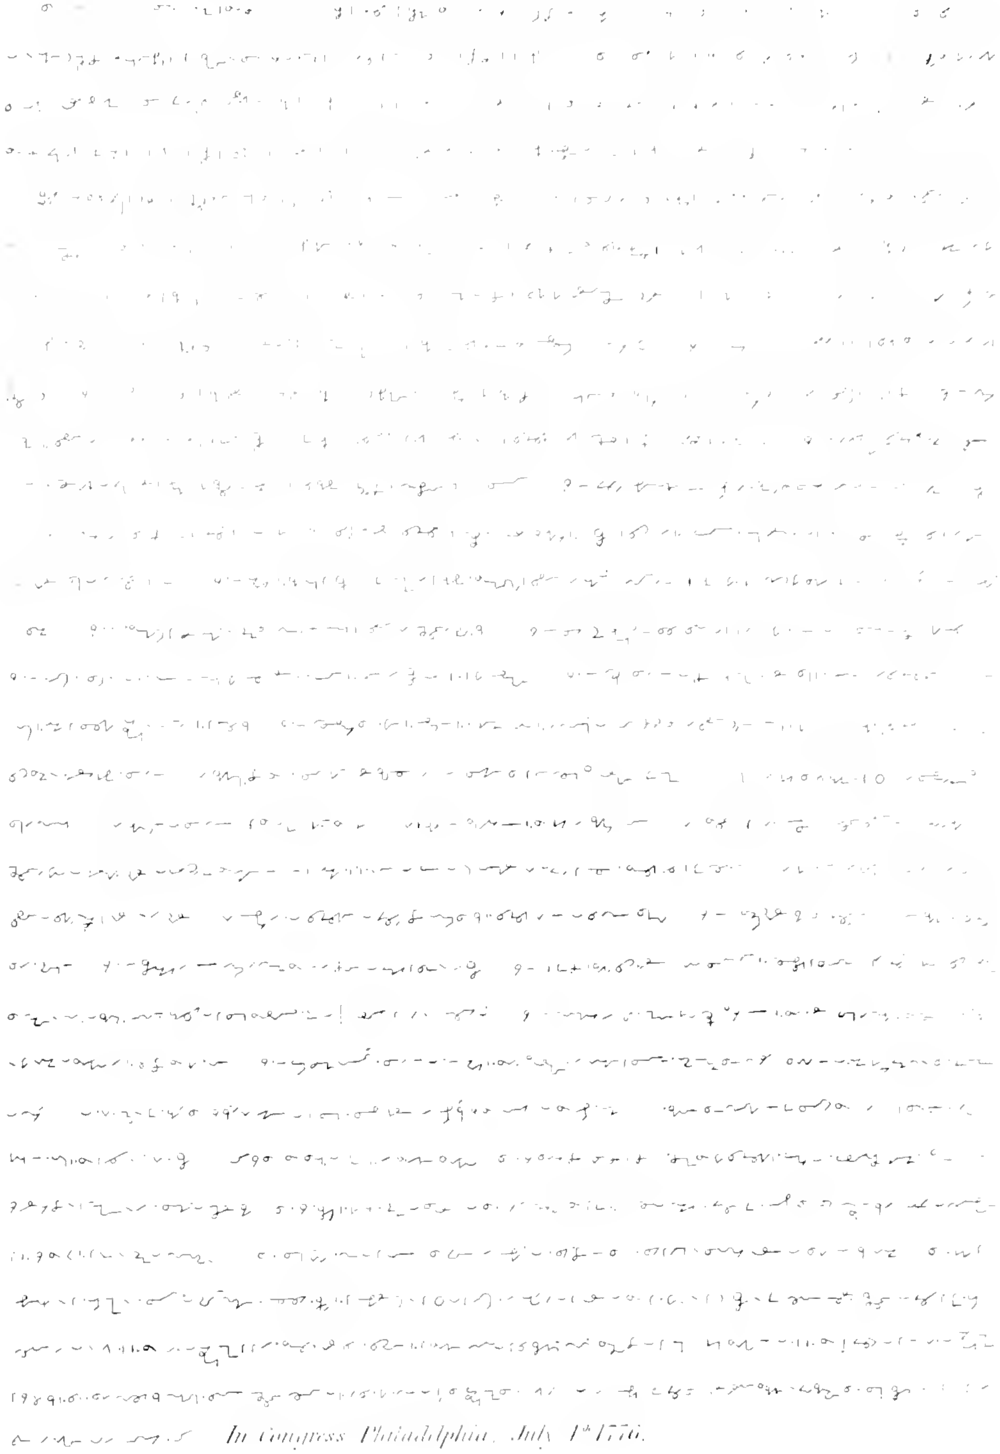


The succeeding passage is a form for following a Speaker more easily by using a few vowel points and not lifting the pen till a word is finished



DECLARATION OF AMERICAN INDEPENDENCE.

The following is a Fac Simile from the hand of M.T.C. Gould



In Congress Philadelphia, July 4th 1776.

John Hancock.
